The connection details dialog box has a **Libraries** path where it will download JAR libraries from the eXist server. If you are using Oxygen XML Editor version 25.0 or older with eXist version 6.2.0 or newer and the final connection to the server does not work, you need to remove

all libraries with the pattern `log4j-*.jar` from the folder of downloaded libraries because they may interfere with the logging in Oxygen XML Editor.

3. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

Attention:
Oxygen XML Editor has been tested to work with the latest stable *eXist* version (version 6). It might work with previous *eXist* versions, but they have not been tested and cannot be guaranteed to be compatible.

How to Configure an eXist Connection Manually

Attention:
For this manual procedure, you need to already have an *eXist* database server installed. Also, Oxygen XML Editor has been tested to work with the latest stable *eXist* version (version 6). It might work with previous *eXist* versions, but they have not been tested and cannot be guaranteed to be compatible.

Tip:
There is an easier way to configure an *eXist* database connection using a built-in wizard. For more information, see How to Configure an eXist Connection Using the Built-in Wizard *(on page 2152)*.

Step 1: Configure eXist Data Source Drivers

Oxygen XML Editor supports *eXist* database server versions up to and including version 5.0. To configure a data source for an *eXist* database, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Data Sources** panel.
3. Enter a unique name for the data source.
4. Select *eXist* from the driver **Type** drop-down menu.
5. Click the **Add Files** button to add the *eXist* driver files. The following driver files should be added and they are found in the installation directory of the *eXist* database server. Make sure you copy the files from the installation of the *eXist* server where you want to connect from Oxygen XML Editor.
   - The `exist.jar` file located in the base directory (if present, depending on the server version).
   - All JAR files in the `lib/core/` directory (if present) or all JAR files located in the `lib` directory except for the JAR libraries with the pattern `log4j-*.jar`, which may interfere with the logging in Oxygen XML Editor.
6. Click the **OK** button to finish the data source configuration.

Step 2: Configure an eXist Connection

To configure a connection to an *eXist* database, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select a previously configured *eXist* data source from the **Data Source** drop-down menu.
5. Enter the connection details:
    a. Set the URI to the installed *eXist* engine in the **XML DB URI** field.
    b. Set the user name in the **User** field.
    c. Set the password in the **Password** field.
    d. Enter the start collection in the **Collection** field.

    eXist organizes all documents in hierarchical collections. Collections are like directories. They are used to group related documents together. This text field allows the user to set the default collection name.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

Resources

For more information about running XQuery against an *eXist* XML database, watch our video demonstration:

https://www.youtube.com/embed/Yoc5h1zSddA

eXist Contextual Menu Actions

While browsing *eXist* database connections in the **Data Source Explorer** view *(on page 2133)*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the **Data Sources** preferences page *(on page 285)* where you can configure both data sources and connections.

Disconnect (when connected)

Stops the connection.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Container Level Nodes

New File or New Document

Creates a new file on the connection, in the current folder.

New Collection

Creates a new collection on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Paste

Pastes the copied selection.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus

back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Save As

Allows you to save the selected resource as a file on disk.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the **Compare Files** tool *(on page 484)*.

MarkLogic Database Connections (Deprecated)

Oxygen XML Editor Enterprise edition includes support for MarkLogic database connections. Once you configure a MarkLogic connection *(on page 2158)*, you can use the **Data Source Explorer** view *(on page 2133)* to display all the application servers that are configured on the MarkLogic server. You can expand each application server and view all of its configured modules, and the **Data Source Explorer** view *(on page 2133)* allows you to open and edit these modules.

Note:
To browse modules located in a database, directory properties must be associated with them. These directory properties are generated automatically if the *directory creation* property of the database is set to automatic. If this property is set to **manual** or **manual-enforced**, add the directory properties of the modules manually, using the XQuery function `xdmp:directory-create()`. For example, for two documents with the `/code/modules/main.xqy` and `/code/modules/imports/import.xqy` IDs, run the following query:

```
(xdmp:directory-create('/code/modules/'), xdmp:directory-create('/code/modules/imports/'))
```

For more information about directory properties, go to: http://blakeley.com/blogofile/2012/03/19/directory-assistance/.

MarkLogic and XQuery

MarkLogic connections can be used in conjunction with XQuery scripts to debug and solve problems with XQuery transformations. XQuery modules can also be validated using a MarkLogic server to allow to you to spot possible issues without the need of actually executing the XQuery script.

When debugging XQuery files with MarkLogic *(on page 2161)*, you can use the **Data Source Explorer** view *(on page 2133)* to open the files from the application server that is involved in the debugging process. By using the **Data Source Explorer** view *(on page 2133)*, any imported modules are better identified by the MarkLogic server. You can also use step actions and breakpoints *(on page 2163)* in the modules to help identify problems.

Modules Container

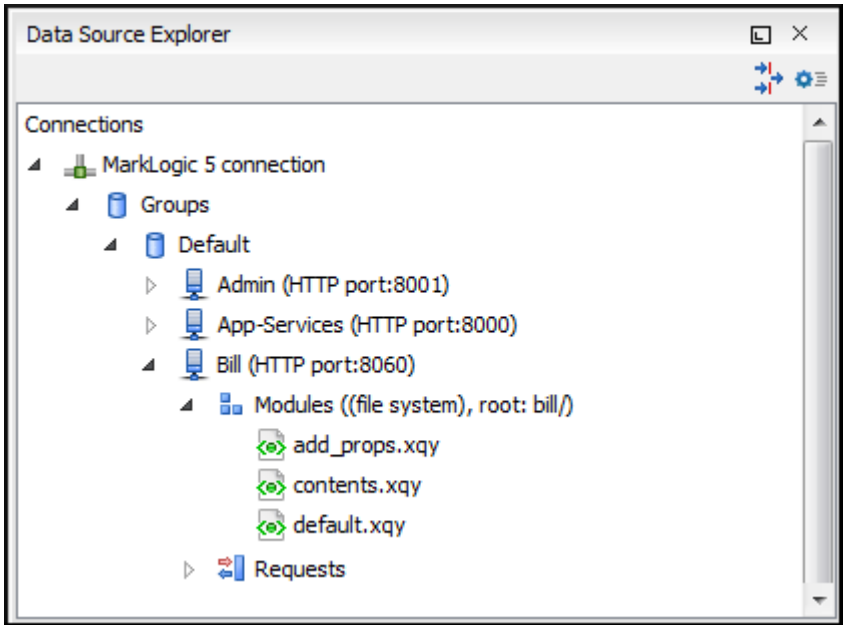
For each Application server (for example: *Bill (HTTP port:8060)*), you have access to the XQuery modules that are visible to that server. When editing, executing, or debugging XQuery it is recommended to open the XQuery files from this **Modules** container.

Note:
You can also manage resources for a MarkLogic database through a WebDAV connection, although it is not recommended if you work with XQuery files since imported modules may not be resolved correctly.

Requests Container

Each MarkLogic application server includes a **Requests** container. In this container, Oxygen XML Editor displays both queries that are stopped for debugging purposes and queries that are still running. To clean up the entire **Requests** container at the end of your session, right-click it and use the **Cancel all requests** action *(on page 2165)*.

Figure 547. MarkLogic Connection in Data Source Explorer



Configuring a MarkLogic Database Connection

Note that this feature is available in Oxygen XML Editor Enterprise edition only.

Follow this procedure to configure the support for a MarkLogic database connection:

1. Download the MarkLogic driver from MarkLogic Community site.
2. Configure MarkLogic *Data Source* drivers *(on page 2158)*.
3. Configure a MarkLogic *Connection (on page 2159)*.
4. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

Related Information:
MarkLogic Development in Oxygen XML Editor *(on page 2160)*

How to Configure MarkLogic Data Source Drivers

Notes:

- Available in the Enterprise edition only.
- Oxygen XML Editor supports MarkLogic version 4.0 or later.

To configure a data source for MarkLogic, follow this procedure:

1. Download the **XCC Java distribution** zip file from: http://developer.marklogic.com/products/xcc.
2. Unzip the downloaded archive.

3. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
4. Click the **New** button in the **Data Sources** panel.
5. Enter a unique name for the data source.
6. Select *MarkLogic* from the driver **Type** drop-down list.
7. Click the **Add Files** button and select the MarkLogic driver file from the `lib` folder of the archive that you downloaded and unzipped. The driver file name is `marklogic-xcc-{server_version}.jar`, where *{server_version}* is the MarkLogic server version.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to configure your MarkLogic Connection *(on page 2159)*.

How to Configure a MarkLogic Connection

Notes:

- Available in the Enterprise edition only.
- Oxygen XML Editor supports MarkLogic version 4.0 or later.

To configure a connection to a MarkLogic database, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select a previously configured MarkLogic data source from the **Data Source** drop-down menu.
5. Enter the connection details.

    a. The host name or IP address of the installed MarkLogic engine in the **XDBC Host** field. Oxygen XML Editor uses XCC connector to interact with MarkLogic XDBC server and requires the basic authentication schema to be set. Starting with version MarkLogic 4.0 the default authentication method when you create an HTTP or WebDAV Server is *digest*, so make sure to change it to *basic*.

    b. Set the port number of the MarkLogic engine in the **Port** field. A MarkLogic XDBC application server must be configured on the server on this port. This XDBC server will be used to process XQuery expressions against the server. Later, if you want to change the XDBC server, instead of editing the configuration just use the **Use it to execute queries** action *(on page 2164)* from Data Source Explorer.

    c. Set the user name to access the MarkLogic engine in the **User** field.

    d. Set the password to access the MarkLogic engine in the **Password** field.

e. Optionally, in the **WebDAV URL** field, set the URL used for browsing the MarkLogic database in the **Data Source Explorer** view *(on page 2133)*.
The **Database** field specifies the database that will have the XQuery expressions executed. If you set this option to default, the database associated to the application server of the configured port is used.

6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

MarkLogic Development in Oxygen XML Editor

The Oxygen XML Editor support for MarkLogic includes features designed for developers, such as debugging XQuery transformations, remote and collaborative debugging, XQuery editing and validation, and an XQuery builder *(on page 1052)* that helps to improve productivity.

Working with XQuery Files

MarkLogic supports working with XQuery files to create queries over stored XML content. You can open an XQuery file, configure a transformation scenario to match your MarkLogic connection, write the XQuery, and then execute it.

When editing XQuery modules stored on the MarkLogic server, the **Outline** view *(on page 1050)* collects and displays all the functions from all imported modules. The *Content Completion Assistant (on page 3418)* also presents all of these functions along with the latest built-in XQuery functions in accordance with the server version.

When developing queries for MarkLogic, it is best to open the resources from the **Data Source Explorer** view *(on page 2133)*. When you execute or debug XQuery files opened from this view, imported modules can be resolved better by the MarkLogic server. Another advantage is that validation is automatically performed on the MarkLogic server, including any imported modules.

XQuery Debugging

Oxygen XML Editor allows you to use MarkLogic connections to debug real applications that use XQuery (for example, web applications that trigger XQuery executions). By setting the server in debug mode, you can intercept all the XQuery scripts that run on that server. Oxygen XML Editor connects to the MarkLogic server, shows you the running XQuery scripts, and allows you to debug them. The remote debugging support also allows you to debug collaboratively. Multiple users can participate in the same debugging session. You can start a debugging session and another user can continue it, and vice versa.

Working with Modules

MarkLogic has a concept of two types of XQuery modules, *library* and *main* modules. A *library* module is used to define functions. Library modules cannot be evaluated directly. They are imported, either from other library

modules or from main modules. A *main* module is used as an entry point that can be executed as an XQuery program. For more information on these types of modules, see XQuery Library Modules and Main Modules.

When working with *library* modules, you need to create a validation scenario and associate it with the module. In the validation scenario you need to specify a main module as the entry point for validation. The modules need to be deployed on a MarkLogic server because Oxygen XML Editor will request the server to validate the modules.

To validate *library* modules stored on a MarkLogic server, follow these steps:

1. Configure a MarkLogic database connection *(on page 2158)*.
2. Expand the MarkLogic connection in the **Data Source Explorer** view *(on page 2133)* and open the *library* modules. The *main* module must also be opened from the **Data Source Explorer** view *(on page 2133)*.
3. Configure a validation scenario *(on page 799)* for each *library* module. Specify the *main* module in the **URL of the file to validate** field.

   Result: Validation is done on the server that contains the *main* module. The *main* module and all other *library* modules involved in the validation must be saved. Otherwise, the server will validate what was saved on the server, without the uncommitted changes. Also, the *Content Completion Assistant (on page 3418)* and the **Outline** view *(on page 1050)* should now present the functions from all the modules.

Related Information:
Debugging with MarkLogic *(on page 2161)*
Configuring a MarkLogic Database Connection *(on page 2158)*

Debugging with MarkLogic

Oxygen XML Editor includes support for debugging XQuery transformations that are executed against a MarkLogic database.

To use a debugging session against the MarkLogic engine, follow these steps:

1. Configure a MarkLogic data source *(on page 2158)* and a MarkLogic connection *(on page 2159)*.
2. Make sure that the debugging support is enabled in the MarkLogic server that Oxygen XML Editor accesses. On the server side, debugging must be activated in the XDBC server and in the *Task Server* section of the server control console (the switch *debug allow*). If the debugging is not activated, the MarkLogic server reports a **DBG-TASKDEBUGALLOW** error.

   Note:
   An XDBC application server must be running to connect to the MarkLogic server and this XDBC server will be used to process XQuery expressions against the server. You can change the XDBC application server that Oxygen XML Editor uses to process XQuery expressions by

selecting the **Use it to execute queries** action *(on page 2164)* from the contextual menu in the **Data Source Explorer** view *(on page 2133)*.

3. Open the XQuery file and start the debugging process.
   - If you want to debug an XQuery file stored on the MarkLogic server, it is recommended to use the **Data Source Explorer** view *(on page 2133)* and open the file from the application server that is involved in the debugging process. This improves the resolving of any imported modules.
   - The MarkLogic XQuery debugger integrates seamlessly into the XQuery Debugger *perspective (on page 358)*. If you have a MarkLogic validation scenario configured for the XQuery file, you can choose to debug the scenario *(on page 2236)* directly.
   - Otherwise, switch to the **XQuery Debugger** *perspective (on page 3422)*, open the XQuery file in the editor, and select the MarkLogic connection in the XQuery engine selector from the debug control toolbar *(on page 2219)*.

     For general information about how a debugging session is started and controlled, see the Working with the Debugger *(on page 2236)* section.

In a MarkLogic debugging session, you can use step actions and *breakpoints (on page 2240)* to help identify problems. When you add a *breakpoint (on page 2241)* on a line where the debugger never stops, Oxygen XML Editor displays a warning message. These warnings are displayed for *breakpoints* you add either in the main XQuery (which you can open locally or from the server) or for *breakpoints* you add in any XQuery that is opened from the connection that participates in the debugging session. For more information, see Using Breakpoints for Debugging Queries that Import Modules with MarkLogic *(on page 2163)*.

Remote Debugging with MarkLogic

Oxygen XML Editor allows you to debug remote applications that use XQuery (for example, web applications that trigger XQuery executions). Oxygen XML Editor connects to a MarkLogic server, shows you the running XQuery scripts and allows you to debug them. You can even pause the scripts so that you can start the debugging queries in the exact context of the application. You can also switch a server to debug mode to intercept all XQuery scripts.

Oxygen XML Editor also supports collaborative debugging. This feature allows multiple users to participate in the same debugging session. You can start a debugging session and at a certain point, another user can continue it.

Important:
When using the remote debugging feature, the HTTP and the XDBC servers involved in the debugging session must have the same module configuration.

Resources

For more information about the XQuery debugger for MarkLogic, watch our video demonstration:

https://www.youtube.com/embed/eQ4ThDZq1bk

Related Information:
MarkLogic Development in Oxygen XML Editor *(on page 2160)*
Configuring a MarkLogic Database Connection *(on page 2158)*

Using Breakpoints for Debugging Queries that Import Modules with MarkLogic

When debugging queries that imports modules stored in the database, it is recommended to place *breakpoints (on page 2240)* in the modules. When starting a new debugging session, make sure that the modules that you will debug are already opened in the editor. This is necessary so that the *breakpoints* in all the modules will be considered. Also, make sure that there are no other open modules that are not involved in the current debugging session.

To place *breakpoints* in the modules, use the following procedure:

1. In the **Data Source Explorer** view *(on page 2133)*, open all the modules from the  **Modules** container of the XDBC application server *(on page 2159)* that performs the debugging.
2. Set *breakpoints (on page 2241)* in the module as needed.
3. Continue debugging *(on page 2236)* the query.

If you get a warning that the *breakpoints* failed to initialize, try the following solutions:

- Check the **Breakpoints** view *(on page 2224)* and make sure there are no older *breakpoints* (set on resources that are not part of the current debugging context).
- Make sure you open the modules from the context of the application server that does the debugging and place *breakpoints* there.

Related Information:
MarkLogic Database Connections (Deprecated) *(on page 2156)*
MarkLogic Development in Oxygen XML Editor *(on page 2160)*

Peculiarities and Limitations of the MarkLogic Debugger

MarkLogic debugger has the following peculiarities and limitations:

- Debugging support is only available for MarkLogic server versions 4.0 or newer.
- For MarkLogic server versions 4.0 or newer, there are three XQuery syntaxes that are supported: *'0.9-ml' (inherited from MarkLogic 3.2)*, *'1.0-ml'*, and *'1.0'*.
- All declared variables are presented as strings. The **Value** column of the **Variables** view contains the expression from the variable declaration. It can be evaluated by copying the expression with the **Copy value** action from the contextual menu of the **Variables** view *(on page 2234)* and pasting it in the **XWatch** view *(on page 2226)*.

- There is no support for output to source mapping *(on page 2237)*.
- There is no support for showing the trace *(on page 2231)*.
- You can only set breakpoints *(on page 2224)* in imported modules in one of the following cases:
  - When you open the module from the context of the application server involved in the debugging, using the **Data Source Explorer** view *(on page 2133)*.
  - When the debugger automatically opens the modules in the Editor.
- No *breakpoints (on page 2240)* are set in modules from the same server that are not involved in the current debugging session.
- No support for profiling *(on page 2241)* when an XQuery transformation is executed in the debugger.

MarkLogic Contextual Menu Actions

While browsing MarkLogic connections in the **Data Source Explorer** view *(on page 2133)*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the **Data Sources** preferences page *(on page 285)* where you can configure both data sources and connections.

Disconnect (when connected)

Stops the connection.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Container Level Nodes

Enable Debug Mode

Switches the server to a debugging mode. For more information, see MarkLogic debugging sessions *(on page 2161)*.

Use it to Execute Queries

The server will be used to process XQuery expressions against it.

Refresh

Performs a refresh on the selected node.

Module or Folder Level Nodes

Export

Allows you to export the folder on the remote connection to a local folder.

Refresh

Performs a refresh on the selected node.

Requests Level Nodes

Refresh

Performs a refresh on the selected node.

Cancel all requests

Cancels all queries that are either running or stopped on the application server. You can use this action to clean up the entire **Requests** container at the end of your sessions.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Refresh

Performs a refresh on the selected node.

Compare

Compares two selected resources using the **Compare Files** tool *(on page 484)*.

Configuring a MarkLogic Database Connection *(on page 2158)*
MarkLogic Development in Oxygen XML Editor *(on page 2160)*
Debugging with MarkLogic *(on page 2161)*

MySQL Database Connections (Deprecated)

Oxygen XML Editor includes support for MySQL database connections. Oxygen XML Editor allows you to browse the structure of a SQL Server database in the **Data Source Explorer** view *(on page 2133)*, open tables in the **Table Explorer** view *(on page 2135)*, and perform various operations on the resources in the repository.

Configuring a MySQL Database Connection

To configure the support for a MySQL database, follow this procedure:

1. Configure MySQL *Data Source* drivers *(on page 2166)*.
2. Configure a MySQL *Connection*. *(on page 2167)*
3. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

How to Configure MySQL Data Source Drivers

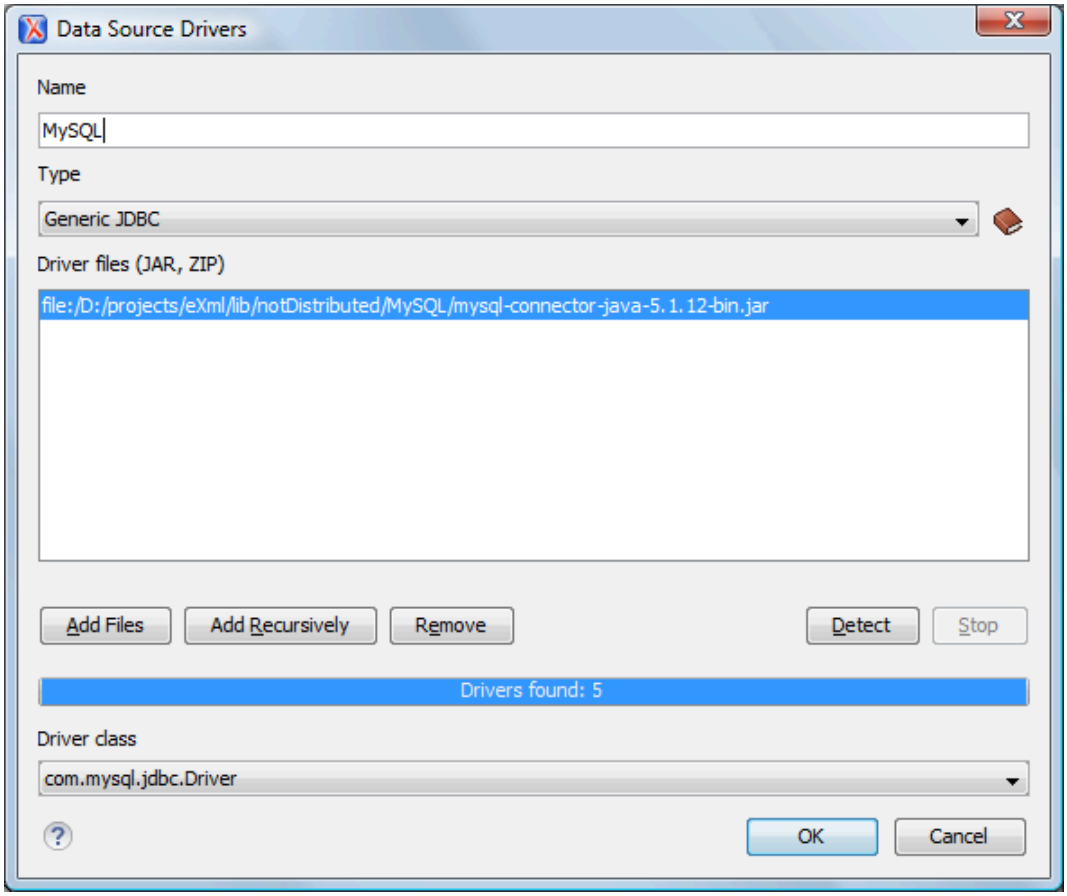
To connect to a MySQL server, you need to create a generic JDBC type data source based on the MySQL JDBC driver available on the MySQL website.

To configure this data source, follow these steps:

1. Go to https://www.oxygenxml.com/database_drivers.html and download the appropriate MySQL driver.
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
3. Click the **New** button in the **Data Sources** panel.

   The dialog box for configuring a data source is opened.

Figure 548. Data Source Drivers Configuration Dialog Box



4. Enter a unique name for the data source.
5. Select *Generic JDBC* in the driver **Type** drop-down list.
6. Click the **Add Files** button and select the MySQL driver file that you downloaded.

   The driver file for the MySQL server is called `mysql-com.jar`.
7. Select the most appropriate **Driver class**.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to configure your MySQL connection *(on page 2167)*.

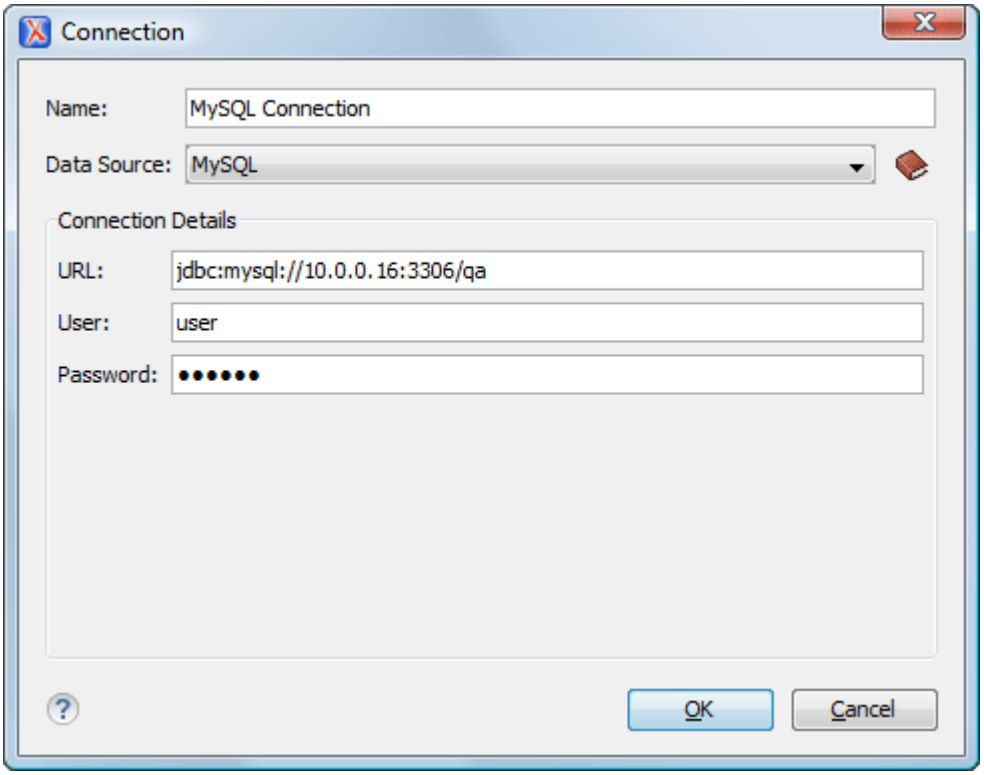
How to Configure a MySQL Connection

To configure a connection to a MySQL server, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

Figure 549. Connection Configuration Dialog Box



3. Enter a unique name for the connection.
4. Select the *MySQL* data source in the **Data Source** drop-down list.
5. Enter the connection details.
    a. Enter the URL of the MySQL server.
    b. Enter the user name for the connection to the MySQL server.
    c. Enter the password for the connection to the MySQL server.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

Generic JDBC Database Connections

Oxygen XML Editor includes support for Generic JDBC database connections.

Configuring a Generic JDBC Database Connection

To configure the support for a generic JDBC database, follow this procedure:

1. Configure Generic JDBC *Data Source* drivers *(on page 2169)*.
2. Configure a Generic JDBC *Connection (on page 2169)*.
3. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

How to Configure Generic JDBC Data Source Drivers

Starting with version 17, Oxygen XML Editor comes bundled with Java 11, which does not provide built-in access to JDBC-ODBC data sources. To access such sources, you need to find an alternative JDBC-ODBC bridge or use a platform-independent distribution of Oxygen XML Editor along with a Java VM version 7 or 6.

To configure a generic JDBC data source, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Data Sources** panel.
3. Enter a unique name for the data source.
4. Select *Generic JDBC* in the driver **Type** drop-down list.
5. Add the driver file(s) using the **Add Files** button.
6. Select the most appropriate **Driver class**.
7. Click the **OK** button to finish the data source configuration.
8. Continue on to configure a generic JDBC connection *(on page 2169)*.

How to Configure a Generic JDBC Connection

To configure a connection to a generic JDBC database, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select the *Generic JDBC* data source in the **Data Source** drop-down menu.
5. Enter the connection details.
    a. Enter the URL of the generic JDBC database, with the following format: `jdbc: <subprotocol>: <subname>`.
    b. Enter the user name for the connection to the generic JDBC database.
    c. Enter the password for the connection to the generic JDBC database.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

JDBC-ODBC Database Connections

Oxygen XML Editor includes support for JDBC-ODBC database connections.

How to Configure a JDBC-ODBC Connection

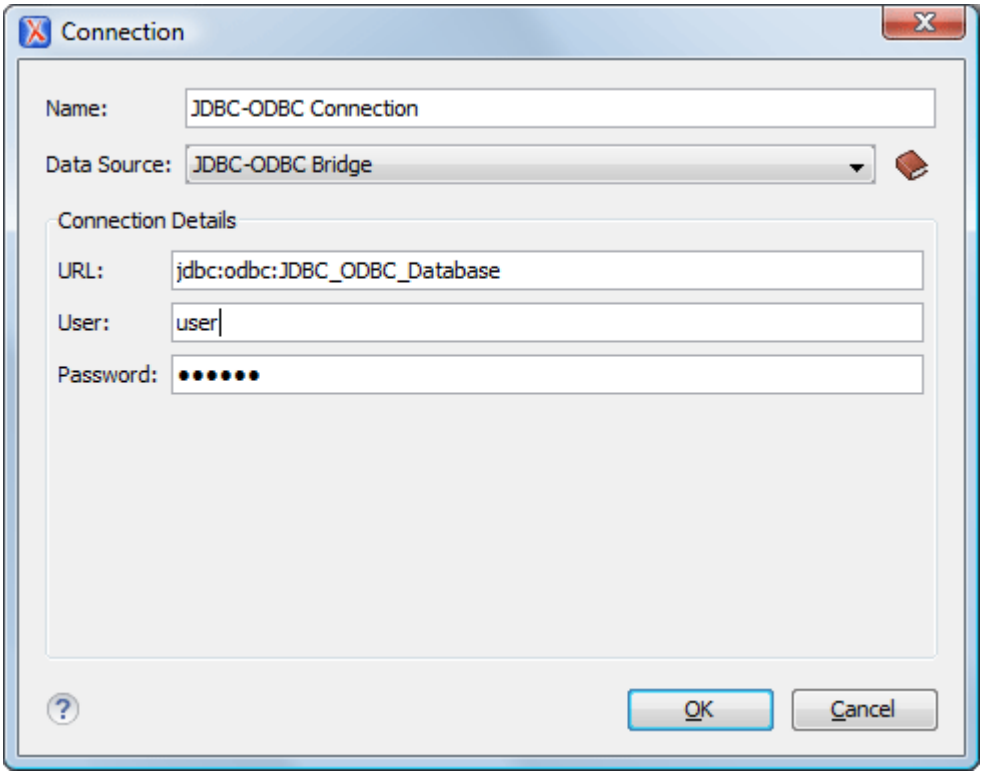
Starting with version 17, Oxygen XML Editor comes bundled with Java 11, which does not provide built-in access to JDBC-ODBC data sources. To access such sources, you need to find an alternative JDBC-ODBC bridge or use a platform-independent distribution of Oxygen XML Editor along with a Java VM version 7 or 6.

To configure a connection to an ODBC data source, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

   Figure 550. Connection Configuration Dialog Box



3. Enter a unique name for the connection.
4. Select *JDBC-ODBC Bridge* in the **Data Source** drop-down list.
5. Enter the connection details.
   a. Enter the URL of the ODBC source.
   b. Enter the user name of the ODBC source.
   c. Enter the password of the ODBC source.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

BaseX Database Connections

Oxygen XML Editor includes support for BaseX database connections using a WebDAV connection. BaseX is a light-weight XML database engine and XQuery processor. Oxygen XML Editor allows you to browse the structure of a BaseX database in the **Data Source Explorer** view *(on page 2133)* and perform XQuery executions.

How to Configure a BaseX Connection

To configure a BaseX connection, follow these steps:

1. First of all, make sure the BaseX HTTP Server is started. For details about starting the BaseX HTTP server, go to http://docs.basex.org/wiki/Startup#BaseX_HTTP_Server. The configuration file for the HTTP server is named `.basex` and is located in the BaseX installation directory. This file helps you to find out which port the HTTP server using. The default port for BaseX WebDAV is 8984.
2. To ensure that everything is functioning, open a WebDAV URL inside a browser and check to see if it works. For example, the following URL retrieves a document from a database named TEST: `http://localhost:8984/webdav/TEST/etc/factbook.xml`.
3. Once you are sure that the BaseX WebDAV service is working, you can configure the WebDAV connection in Oxygen XML Editor as described in How to Configure a WebDAV Connection *(on page 2179)*. The WebDAV URL should resemble this: `http://{hostname }:{port}/webdav/`. If the BaseX server is running on your own machine and it has the default configuration, the data required by the WebDAV connection is:
   - WebDAV URL: `http://localhost:8984/webdav`
   - User: `admin`
   - Password: `admin`
4. Once the WebDAV connection is created, to view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

BaseX Contextual Menu Actions

While browsing BaseX connections in the **Data Source Explorer** view *(on page 2133)*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the **Data Sources** preferences page *(on page 285)* where you can configure both data sources and connections.

Disconnect (when connected)

Stops the connection.

New Folder

Creates a new folder on the connection.

Import Files

Allows you to add a new file on the connection, in the current folder.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

New File or New Document

Creates a new file on the connection, in the current folder.

New Folder

Creates a new folder on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Paste

Pastes the copied selection.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

 **Cut**

Removes the current selection and places it in the clipboard.

 **Copy**

Copies the current selection into the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename

Renames the current resource

 **Delete**

Deletes the current container.

 **Refresh**

Performs a refresh on the selected node.

 **Properties**

Shows various properties of the current container.

 **Find/Replace in Files**

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the **Compare Files** tool *(on page 484)*.

Base X XQJ Connection

XQuery execution is possible in a BaseX connection through an XQJ connection.

Important:
The XQJ connector is only capable of running XQuery 1.0 scrips, therefore XQuery 3.0 and 3.1 scripts are not supported.

BaseX XQJ Data Source

First of all, create an XQJ data source as described in How to Configure an XQJ Data Source *(on page 2174)*. The BaseX XQJ API-specific files that must be added in the configuration dialog box are `xqj-api-1.0.jar`, `xqj2-0.1.0.jar` and `basex-xqj-1.2.3.jar` (the version names of the *JAR* file may differ). These libraries can be downloaded from *xqj.net/basex/basex-xqj-1.2.3.zip*. As an alternative, you can also find the libraries in the BaseX installation directory, in the **lib** sub-directory.

BaseX XQJ Connection

The next step is to create an XQJ connection *(on page 2175)*.

For a default BaseX configuration, the following connection details apply (you can modify them when necessary):

- **Port**: 1984
- **serverName**: localhost
- **user**: admin
- **password**: admin

XQuery Execution

Now that the XQJ connection is configured, open the XQuery file you want to execute in Oxygen XML Editor and create an XQuery Transformation *(on page 1588)*. In the **Transformer** drop-down menu, select the name of the XQJ connection you created. Apply the transformation scenario and the XQuery will be executed.

How to Configure an XQJ Data Source

Any transformer that offers an XQJ API implementation can be used when validating XQuery or transforming XML documents. An example of an XQuery engine that implements the XQJ API is Zorba.

1. If your XQJ Implementation is native, make sure the directory containing the native libraries of the engine is added to your system environment variables: to **PATH** - on Windows, to **LD_LIBRARY_PATH** - on Linux, or to **DYLD_LIBRARY_PATH** - on macOS. Restart Oxygen XML Editor after configuring the environment variables.
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
3. Click the **New** button in the **Data Sources** panel.
4. Enter a unique name for the data source.
5. Select **XQuery API for Java (XQJ)** in the **Type** combo box.
6. Click the **Add** button to add XQJ API-specific files.
   You can manage the driver files using the **Add**, **Remove**, **Detect**, and **Stop** buttons.
   Oxygen XML Editor detects any implementation of *javax.xml.xquery.XQDataSource* and presents it in **Driver class** field.
7. Select the most suited driver in the **Driver class** combo box.

8. Click the **OK** button to finish the data source configuration.
9. Continue on to configure the XQJ connection *(on page 2175)*.

How to Configure an XQJ Connection

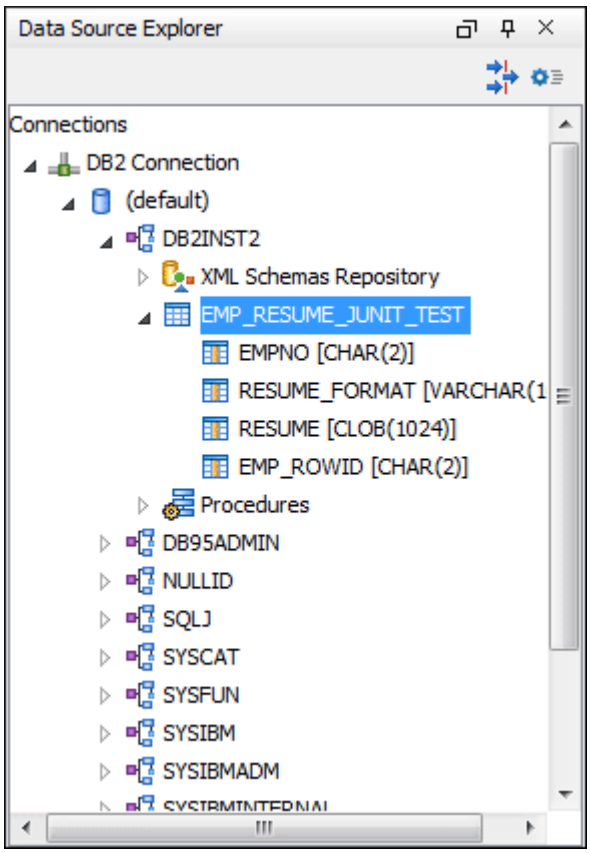
The steps for configuring an XQJ connection are the following:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select one of the previously configured XQJ data sources *(on page 2174)* in the **Data Source** combo box.
5. Fill-in the connection details.
   The properties presented in the connection details table are automatically detected depending on the selected data source.
6. Click the **OK** button to finish the connection configuration.

IBM DB2 Database Connections (Deprecated)

Oxygen XML Editor includes support for IBM DB2 database connections. Oxygen XML Editor allows you to browse the structure of an IBM DB2 database in the **Data Source Explorer** view *(on page 2133)*, open tables in the **Table Explorer** view *(on page 2135)*, and perform various operations on the resources in the repository.

Figure 551. IBM DB2 Database Connection



Configuring an IBM DB2 Database Connection (Deprecated)

To configure the support for the IBM DB2 database, follow this procedure:

1. Go to the IBM website and in the *DB2 Clients and Development Tools* category select the *DB2 Driver for JDBC and SQLJ* download link. Fill out the download form and download the zip file. Unzip the zip file and use the `db2jcc.jar` and `db2jcc_license_cu.jar` files in Oxygen XML Editor for configuring a DB2 data source *(on page 2176)*.
2. Configure IBM DB2 *Data Source* drivers *(on page 2176)*.
3. Configure an IBM DB2 Server *Connection (on page 2177)*.
4. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

How to Configure IBM DB2 Data Source Drivers (Deprecated)

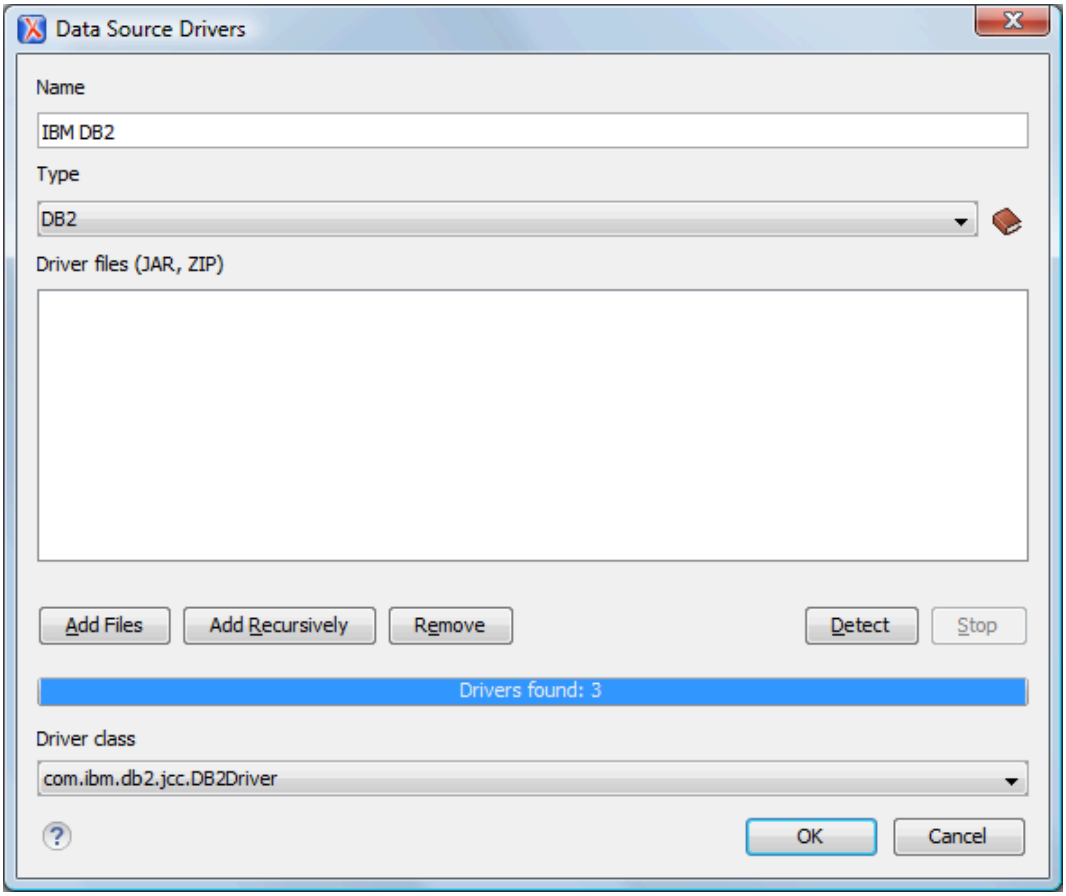
Note:
Available in the Enterprise edition only.

To configure a data source for connecting to an IBM DB2 server, follow these steps:

1. Go to the IBM website and in the *DB2 Clients and Development Tools* category select the *DB2 Driver for JDBC and SQLJ* download link. Fill out the download form and download the zip file.
2. Unzip the downloaded archive.
3. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
4. Click the **New** button in the **Data Sources** panel.

   The dialog box for configuring a data source is opened.

Figure 552. Data Source Drivers Configuration Dialog Box



5. Enter a unique name for the data source.
6. Select *DB2* in the driver **Type** drop-down menu.
7. Click the **Add Files** button and select the IBM DB2 driver files from the archive that you downloaded and unzipped.

   The IBM DB2 driver files are:

   - `db2jcc.jar`
   - `db2jcc_license_cisuz.jar`
   - `db2jcc_license_cu.jar`
8. Select the most appropriate **Driver class**.
9. Click the **OK** button to finish the data source configuration.
10. Continue on to configure your IBM DB2 connection *(on page 2177)*.

How to Configure an IBM DB2 Connection (Deprecated)

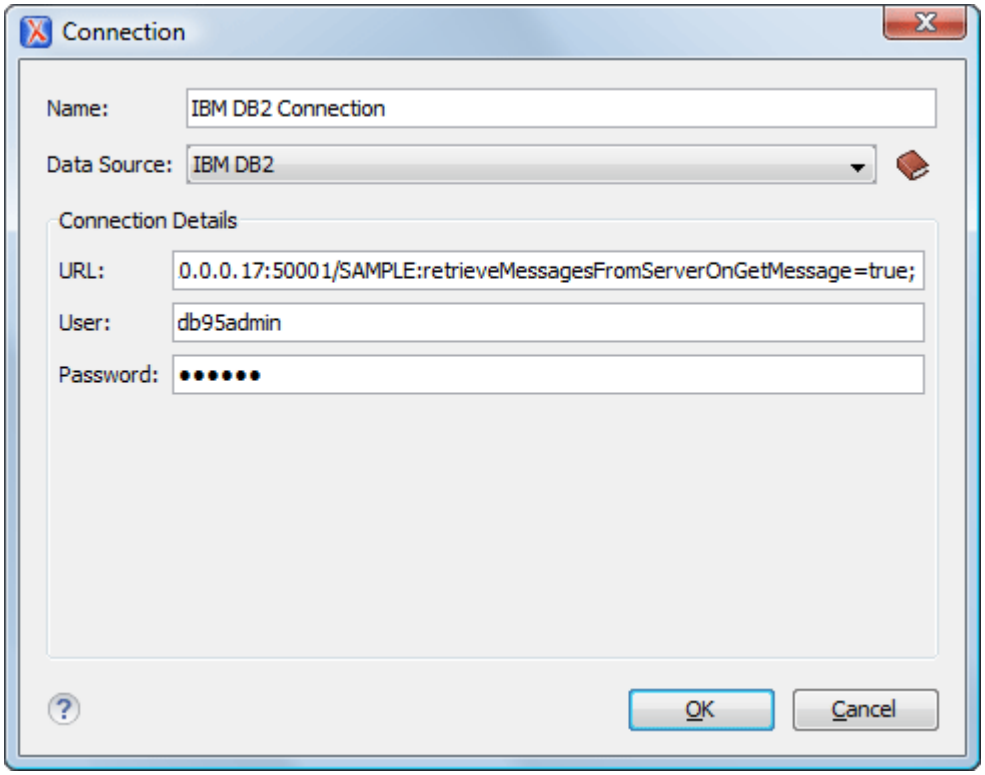
Note:
The support to create an IBM DB2 connection is available in the Enterprise edition only.

To configure a connection to an IBM DB2 server, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

   Figure 553. Connection Configuration Dialog Box



3. Enter a unique name for the connection.
4. Select an *IBM DB2* data source in the **Data Source** drop-down menu.
5. Enter the connection details.
   a. Enter the URL to the installed IBM DB2 engine.
   b. Enter the user name to access the IBM DB2 engine.
   c. Enter the password to access the IBM DB2 engine.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

IBM DB2 Contextual Menu Actions (Deprecated)

General Contextual Menu Actions

For relational databases, the following general actions are available in the contextual menu of the **Data Source Explorer** view *(on page 2133)*, depending on the node where it is invoked:

Refresh

Performs a refresh on the selected node.

Disconnect (available on Connection nodes)

Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

Configure Database Sources (available on Connection nodes)

Opens the **Data Sources** preferences page *(on page 285)* where you can configure both data sources and connections.

Edit (available on Table nodes)

Opens the selected table in the **Table Explorer** view *(on page 2135)*.

Export to XML (available on Table nodes)

Opens the **Export Criteria** dialog box (a thorough description of this dialog box can be found in the Import from Database *(on page 2210)* chapter).

Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the **Data Source Explorer** view *(on page 2133)*, the various nodes in IBM DB2 connections include the following additional contextual menu actions:

XML Schema Repository Level Nodes

Register

Opens a dialog box for adding a new schema file in the DB XML repository. In this dialog box, you enter a collection name and the necessary schema files. Schema dependencies management can be done by using the **Add** and **Remove** buttons.

Schema Level Nodes

Unregister

Removes the selected schema from the XML Schema Repository.

View

Opens the selected schema in Oxygen XML Editor.

WebDAV Connections

Oxygen XML Editor includes support for WebDAV server connections. Oxygen XML Editor allows you to browse the structure of a WebDAV connection in the **Data Source Explorer** view *(on page 2133)* and perform various operations on the resources in the repository.

How to Configure a WebDAV Connection

By default, Oxygen XML Editor contains built-in data source drivers for **WebDAV** connections. Based on this data source, you can create a WebDAV connection for browsing and editing data from a database that provides a WebDAV interface. The connection is available in the **Data Source Explorer** view *(on page 2133)*.

To configure a WebDAV connection, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select one of the WebDAV data sources in the **Data Source** drop-down menu.
5. Enter the connection details:
   a. Set the URL to the WebDAV repository in the field **WebDAV URL**.
   b. Set the user name that is used to access the WebDAV repository in the **User** field.
   c. Set the password that is used to access the WebDAV repository in the **Password** field.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.
   For more information about the WebDAV support in Oxygen XML Editor, watch our video demonstration:

   https://www.youtube.com/embed/vDXO36CqbvM

WebDAV Contextual Menu Actions

While browsing WebDAV connections in the **Data Source Explorer** view *(on page 2133)*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the **Data Sources** preferences page *(on page 285)* where you can configure both data sources and connections.

Disconnect (when connected)

Stops the connection.

New Folder

Creates a new folder on the connection.

Import Files

Allows you to add a new file on the connection, in the current folder.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

New File or New Document

Creates a new file on the connection, in the current folder.

New Folder

Creates a new folder on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Paste

Pastes the copied selection.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system

application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the **Compare Files** tool *(on page 484)*.

SQL Execution Support

The database support in Oxygen XML Editor includes support for writing SQL statements, syntax highlighting, *folding (on page 3420)*, and dragging and dropping from the **Data Source Explorer** view *(on page 2133)*.
It also includes transformation scenarios for executing the statements, and the results are displayed in the **Table Explorer** view *(on page 2135)*.

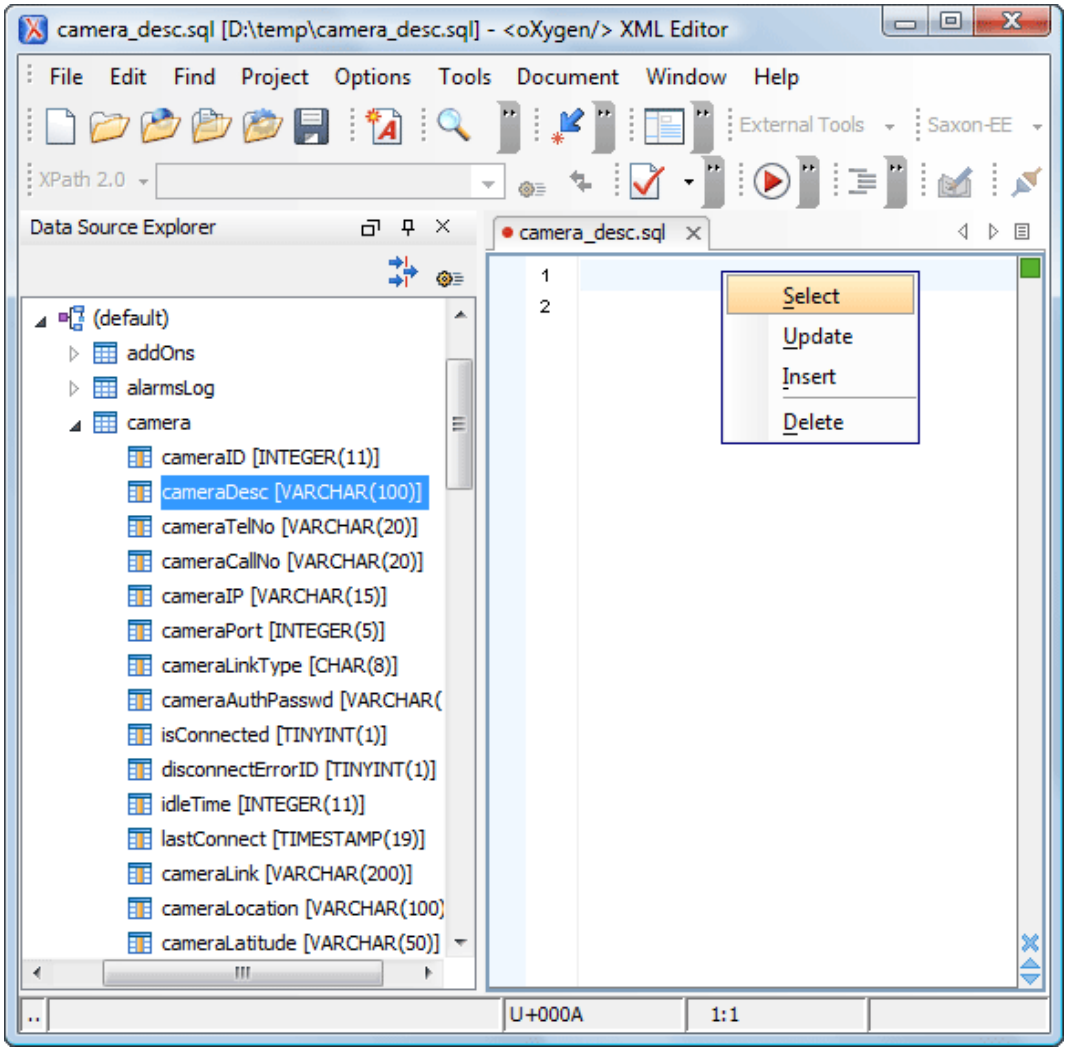
Drag and Drop from Data Source Explorer View

Dragging operations from the **Data Source Explorer** view *(on page 2133)* and dropping them in the SQL Editor allows you to create SQL statements quickly by inserting the names of tables and columns in the SQL statements.

1. Configure a database connection (see the specific procedure for your database server in the Database Connection Support *(on page 2138)* section).
2. Browse to the table you will use in your statement.
3. Drag the table or a column of the table into the editor where a SQL file is open.

   Drag and drop actions are available both on the table and on its fields. A pop-up menu is displayed in the SQL editor.

Figure 554. SQL Statement Editing with Drag and Drop



4. Select the type of statement from the pop-up menu.

   Depending on your choice, dragging a table results in one of the following statements being inserted into the document:

   - **SELECT `*field1*`,`*field2*`, ... FROM `*catalog*`.`*table*`** (for example: `SELECT` `` `DEPT`,`DEPTNAME`,`LOCATION` FROM `camera`.`cameraDesc` ``)
   - **UPDATE `*catalog*`.`*table*` SET `*field1*`=, `*field2*`=,....** (for example: `UPDATE` `` `camera`.`cameraDesc` SET `DEPT`=, `DEPTNAME`=, `LOCATION`= ``)

- **INSERT INTO `*catalog*`. `*table*` (`*field1*`,`*field2*`, ...) VALUES (, ,)** (for example: `INSERT INTO` `` `camera`.`cameraDesc` (`DEPT`,`DEPTNAME`,`LOCATION`) VALUES (, , ) ``)
- **DELETE FROM `*catalog*`. `*table*`** (for example: `DELETE FROM` `` `camera`.`cameraDesc` ``)

Depending on your choice, dragging a column results in one of the following statements being inserted into the document:

- **SELECT `*field*` FROM `*catalog*`. `*table*`** (for example: `SELECT` `` `DEPT` `FROM` `camera`.`cameraDesc` ``)
- **UPDATE `*catalog*`. `*table*` SET `*field*`=** (for example: `UPDATE` `` `camera`.`cameraDesc` `SET` `DEPT`= ``)
- **INSERT INTO `*catalog*`. `*table*` (`*field1*`) VALUES ()** (for example: `INSERT INTO` `` `camera`.`cameraDesc` (`DEPT`) VALUES () ``)
- **DELETE FROM `*catalog*`. `*table*`** (for example: `DELETE FROM` `` `camera`.`cameraDesc` `WHERE` `DEPT`= ``)

SQL Validation

SQL validation support is offered for IBM DB2. Note that if you choose a connection that does not support SQL validation, you will receive a warning when trying to validate. The SQL document is validated using the connection from the associated transformation scenario.

Executing SQL Statements

The steps for executing an SQL statement on a relational database are as follows:

1. Configure a transformation scenario *(on page 1470)* using the **Configure Transformation Scenario(s)** action from the toolbar or the **Document > Transformation** menu.
   A SQL transformation scenario needs a database connection. You can configure a connection using the **Preferences** button from the SQL transformation dialog box.
   The dialog box contains the list of existing scenarios that apply to SQL documents.
2. Set parameter values for SQL placeholders using the **Parameters** button from the SQL transformation dialog box.
   For example, in `SELECT * FROM` `` `test`.`department` `where DEPT = ? or DEPTNAME = ?` `` the two parameters can be configured for the place holders (?) in the transformation scenario.

   When the SQL statement is executed, the first placeholder is replaced with the value set for the first parameter in the scenario, the second placeholder is replaced by the second parameter value, and so on.

   Restriction:
   When a stored procedure is called in an SQL statement executed on an SQL Server database, mixing inline parameter values with values specified using the **Parameters** button of the scenario dialog box is not recommended. This is due to a limitation of the SQL Server driver

for Java applications. An example of stored procedure that is not recommended: `call dbo.Test(22, ?)`.

3. Execute the SQL scenario by clicking the **OK** or **Apply associated** button.

   The result of a SQL transformation is displayed in a view *(on page 558)* at the bottom of the Oxygen XML Editor window.

4. View more complex return values of the SQL transformation in a separate editor panel.
   A more complex value returned by the SQL query (for example, an *XMLTYPE* or *CLOB* value) cannot be displayed entirely in the result table.

   a. Right-click the cell containing the complex value.

   b. Select the action **Copy cell** from the contextual menu.
      The action copies the value in the clipboard.

   c. Paste the value into an appropriate editor.
      For example, you can paste the value in an opened XQuery editor panel of Oxygen XML Editor.

XQuery and Databases

XQuery is a native XML query language that is useful for querying XML views of relational data to create XML results. It also provides the mechanism to efficiently and easily extract information from Native XML Databases (NXD) and relational data. The following database systems supported in Oxygen XML Editor offer XQuery support:

- *Native XML Databases:*
  - eXist
  - MarkLogic (validation support available starting with version 5)
- *Relational Databases:*
  - IBM DB2
  - Microsoft SQL Server (validation support not available)
  - Oracle (validation support not available)

Related information

Editing XQuery Documents *(on page 1046)*

Build Queries with Drag and Drop from the Data Source Explorer View

When a query is edited in the XQuery editor, the XPath expressions can be composed quickly by dragging them from the **Data Source Explorer** view *(on page 2133)* and dropping them into the editor panel.

1. Configure the data source drivers *(on page 2138)* for the particular relational database in the **Data Sources** preferences page *(on page 285)*.
2. Configure the connection *(on page 2138)* for the particular relational database in the **Data Sources** preferences page *(on page 285)*.
3. Browse the connection in the **Data Source Explorer** view *(on page 2133)*, expanded to the table or column that you want to insert in the query.
4. Drag the table or column name to the XQuery editor panel.
5. Drop the table or column name where the XPath expression is needed.

An XPath expression that selects the dragged name is inserted in the XQuery document at the cursor position.

XQuery Validation When Connected to a Database

With Oxygen XML Editor, you can validate your XQuery documents when connected to a database. When you open an XQuery document from a connection that supports validation (for example, MarkLogic, or eXist), by default Oxygen XML Editor uses this connection for validation. If you open an XQuery file using a MarkLogic connection, the validation resolves imports better.

Related Information:
XQuery Validation *(on page 1047)*

XQuery Transformation for Databases

XQuery is designed to retrieve and interpret XML data from any source, whether it is a database or document. Data is stored in relational databases but it is often required that the data be extracted and transformed as XML when interfacing to other components and services. Also, it is an XPath-based querying language supported by most NXD vendors. To perform a query, you need an XQuery transformation scenario.

1. Configure the data source drivers and the connection *(on page 2138)* for the particular database.
2. Configure an XQuery transformation scenario.

    a. Click the **Configure Transformation Scenario** toolbar button or go to menu **Document > Transformation > Configure Transformation Scenario**.

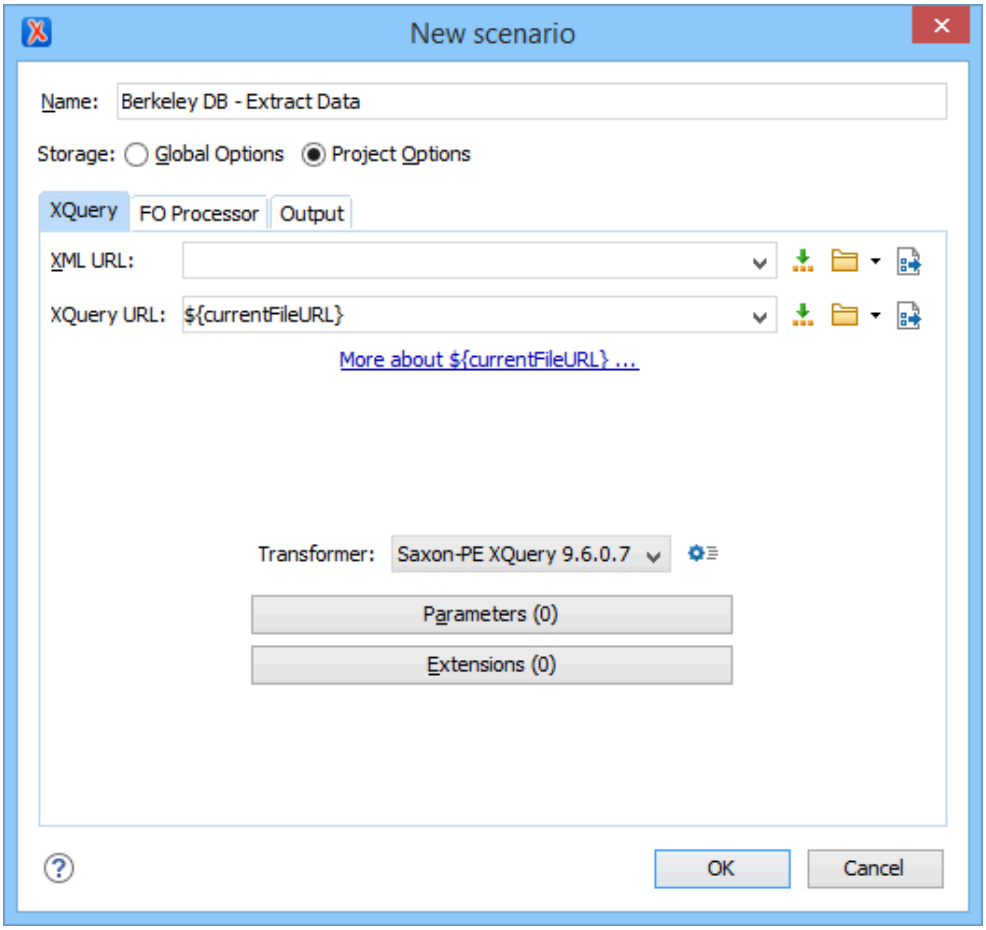
    The **Configure Transformation Scenario** dialog box *(on page 1600)* is opened.

    b. Click the **New** button toward the bottom of the dialog box.

    c. Select **XML Transformation with XQUERY** *(on page 1520)*.

    The **New Scenario** dialog box for configuring an XQuery scenario is opened.

Figure 555. New Scenario Dialog Box



d. Insert the scenario name in the dialog box for editing the scenario.

e. Choose the database connection in the **Transformer** drop-down list.

f. Configure any other parameters as needed.
For an XQuery transformation, the output tab has an option called **Sequence** that allows you to run an XQuery in lazy mode. The amount of data extracted from the database is controlled from the **Size limit on Sequence view** option *(on page 262)* in the **XQuery** preferences page. If you choose **Perform FO Processing** in the **FO Processor** tab, the **Sequence** option is ignored.

g. Click the **OK** button to finish editing the scenario.

Once the scenario is associated with the XQuery file, the query can include calls to specific XQuery functions that are implemented by that engine. The available functions depend on the target database engine selected in the scenario. For example, for eXist, the *Content Completion Assistant (on page 3418)* lists the functions supported by that database engine. This is useful for only inserting calls to the supported functions (standard XQuery functions or extension ones) into the query .

3. Run the transformation scenario.
To view a more complex value returned by the query that cannot be entirely displayed in the XQuery query result table at the bottom of the Oxygen XML Editor window (for example, an XMLTYPE or CLOB value), do the following:

- Right-click that table cell.
- Select the **Copy cell** action from the contextual menu to copy the value into the clipboard.
- Paste the value wherever you need it (for example, in an open XQuery editor panel of Oxygen XML Editor).

Related information

XML Transformation with XQuery *(on page 1520)*
XQuery XQJ Transformation *(on page 2188)*

XQuery XQJ Transformation

XQuery API for Java (XQJ) refers to the common Java API for the XQuery 1.0 specification. The XQJ API enables you to execute XQuery against an XML data source.

Important:
The XQJ connector is only capable of running XQuery 1.0 scrips, therefore XQuery 3.0 and 3.1 scripts are not supported.

Oxygen XML Editor supports any transformer that offers an XQJ API implementation and it be used for validating XQuery or transforming XML documents.

To configure the support for XQJ, do the following:

1. Configure an XQJ *Data Source (on page 2174)*.
2. Configure an XQJ *Connection (on page 2175)*.
3. To view your connection, go to the **Data Source Explorer** view *(on page 2133)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database** *perspective (on page 3422)*.

How to Configure an XQJ Data Source

Any transformer that offers an XQJ API implementation can be used when validating XQuery or transforming XML documents. An example of an XQuery engine that implements the XQJ API is Zorba.

1. If your XQJ Implementation is native, make sure the directory containing the native libraries of the engine is added to your system environment variables: to **PATH** - on Windows, to **LD_LIBRARY_PATH** - on Linux, or to **DYLD_LIBRARY_PATH** - on macOS. Restart Oxygen XML Editor after configuring the environment variables.
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
3. Click the **New** button in the **Data Sources** panel.
4. Enter a unique name for the data source.
5. Select **XQuery API for Java (XQJ)** in the **Type** combo box.
6. Click the **Add** button to add XQJ API-specific files.
   You can manage the driver files using the **Add**, **Remove**, **Detect**, and **Stop** buttons.

Oxygen XML Editor detects any implementation of *javax.xml.xquery.XQDataSource* and presents it in **Driver class** field.

7. Select the most suited driver in the **Driver class** combo box.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to configure the XQJ connection *(on page 2175)*.

How to Configure an XQJ Connection

The steps for configuring an XQJ connection are the following:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select one of the previously configured XQJ data sources *(on page 2174)* in the **Data Source** combo box.
5. Fill-in the connection details.
   The properties presented in the connection details table are automatically detected depending on the selected data source.
6. Click the **OK** button to finish the connection configuration.

XQuery Database Debugging

Oxygen XML Editor includes a debugging interface that helps you to detect and solve problems with XQuery transformations that are executed against MarkLogic databases.

For more information about the debugging support in Oxygen XML Editor, see Debugging XSLT Stylesheets and XQuery Documents *(on page 2217)*.

Debugging with MarkLogic

Oxygen XML Editor includes support for debugging XQuery transformations that are executed against a MarkLogic database.

To use a debugging session against the MarkLogic engine, follow these steps:

1. Configure a MarkLogic data source *(on page 2158)* and a MarkLogic connection *(on page 2159)*.
2. Make sure that the debugging support is enabled in the MarkLogic server that Oxygen XML Editor accesses. On the server side, debugging must be activated in the XDBC server and in the *Task Server* section of the server control console (the switch *debug allow*). If the debugging is not activated, the MarkLogic server reports a **DBG-TASKDEBUGALLOW** error.

Note:
An XDBC application server must be running to connect to the MarkLogic server and this XDBC server will be used to process XQuery expressions against the server. You can change the XDBC application server that Oxygen XML Editor uses to process XQuery expressions by

selecting the **Use it to execute queries** action *(on page 2164)* from the contextual menu in the **Data Source Explorer** view *(on page 2133)*.

3. Open the XQuery file and start the debugging process.
   - If you want to debug an XQuery file stored on the MarkLogic server, it is recommended to use the **Data Source Explorer** view *(on page 2133)* and open the file from the application server that is involved in the debugging process. This improves the resolving of any imported modules.
   - The MarkLogic XQuery debugger integrates seamlessly into the XQuery Debugger *perspective (on page 358)*. If you have a MarkLogic validation scenario configured for the XQuery file, you can choose to debug the scenario *(on page 2236)* directly.
   - Otherwise, switch to the **XQuery Debugger** *perspective (on page 3422)*, open the XQuery file in the editor, and select the MarkLogic connection in the XQuery engine selector from the debug control toolbar *(on page 2219)*.

     For general information about how a debugging session is started and controlled, see the Working with the Debugger *(on page 2236)* section.

In a MarkLogic debugging session, you can use step actions and *breakpoints (on page 2240)* to help identify problems. When you add a *breakpoint (on page 2241)* on a line where the debugger never stops, Oxygen XML Editor displays a warning message. These warnings are displayed for *breakpoints* you add either in the main XQuery (which you can open locally or from the server) or for *breakpoints* you add in any XQuery that is opened from the connection that participates in the debugging session. For more information, see Using Breakpoints for Debugging Queries that Import Modules with MarkLogic *(on page 2163)*.

Remote Debugging with MarkLogic

Oxygen XML Editor allows you to debug remote applications that use XQuery (for example, web applications that trigger XQuery executions). Oxygen XML Editor connects to a MarkLogic server, shows you the running XQuery scripts and allows you to debug them. You can even pause the scripts so that you can start the debugging queries in the exact context of the application. You can also switch a server to debug mode to intercept all XQuery scripts.

Oxygen XML Editor also supports collaborative debugging. This feature allows multiple users to participate in the same debugging session. You can start a debugging session and at a certain point, another user can continue it.

Important:
When using the remote debugging feature, the HTTP and the XDBC servers involved in the debugging session must have the same module configuration.

Resources

For more information about the XQuery debugger for MarkLogic, watch our video demonstration:

https://www.youtube.com/embed/eQ4ThDZq1bk

MarkLogic Development in Oxygen XML Editor *(on page 2160)*
Configuring a MarkLogic Database Connection *(on page 2158)*

Using Breakpoints for Debugging Queries that Import Modules with MarkLogic

When debugging queries that imports modules stored in the database, it is recommended to place *breakpoints (on page 2240)* in the modules. When starting a new debugging session, make sure that the modules that you will debug are already opened in the editor. This is necessary so that the *breakpoints* in all the modules will be considered. Also, make sure that there are no other open modules that are not involved in the current debugging session.

To place *breakpoints* in the modules, use the following procedure:

1. In the **Data Source Explorer** view *(on page 2133)*, open all the modules from the  **Modules** container of the XDBC application server *(on page 2159)* that performs the debugging.
2. Set *breakpoints (on page 2241)* in the module as needed.
3. Continue debugging *(on page 2236)* the query.

If you get a warning that the *breakpoints* failed to initialize, try the following solutions:

- Check the **Breakpoints** view *(on page 2224)* and make sure there are no older *breakpoints* (set on resources that are not part of the current debugging context).
- Make sure you open the modules from the context of the application server that does the debugging and place *breakpoints* there.

Related Information:
MarkLogic Database Connections (Deprecated) *(on page 2156)*
MarkLogic Development in Oxygen XML Editor *(on page 2160)*

Peculiarities and Limitations of the MarkLogic Debugger

MarkLogic debugger has the following peculiarities and limitations:

- Debugging support is only available for MarkLogic server versions 4.0 or newer.
- For MarkLogic server versions 4.0 or newer, there are three XQuery syntaxes that are supported: *'0.9-ml' (inherited from MarkLogic 3.2)*, *'1.0-ml'*, and *'1.0'*.
- All declared variables are presented as strings. The **Value** column of the **Variables** view contains the expression from the variable declaration. It can be evaluated by copying the expression with the **Copy value** action from the contextual menu of the **Variables** view *(on page 2234)* and pasting it in the **XWatch** view *(on page 2226)*.

- There is no support for output to source mapping *(on page 2237)*.
- There is no support for showing the trace *(on page 2231)*.
- You can only set breakpoints *(on page 2224)* in imported modules in one of the following cases:
  - When you open the module from the context of the application server involved in the debugging, using the **Data Source Explorer** view *(on page 2133)*.
  - When the debugger automatically opens the modules in the Editor.
- No *breakpoints (on page 2240)* are set in modules from the same server that are not involved in the current debugging session.
- No support for profiling *(on page 2241)* when an XQuery transformation is executed in the debugger.

Integration with Microsoft SharePoint

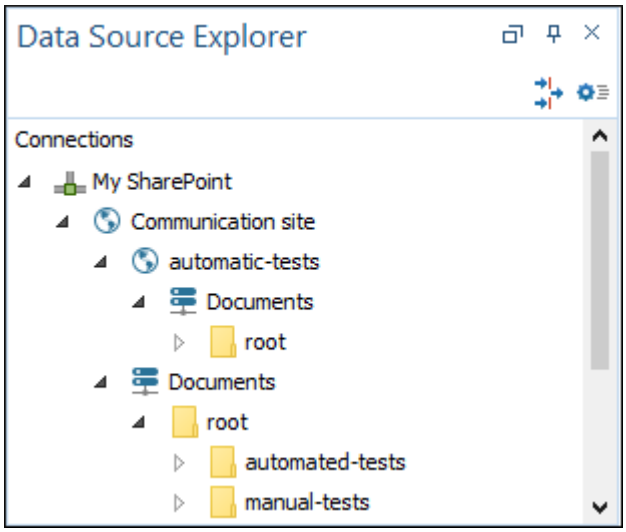
Restriction:
The SharePoint integration is only available in the Enterprise edition of Oxygen XML Editor.

Oxygen XML Editor provides support for browsing and managing SharePoint connections in the **Data Source Explorer** view *(on page 2133)* and there is also a specialized **SharePoint Browser** view *(on page 2197)*. You can easily create new resources on the repository, copy and move them using contextual actions or the drag and drop support, or edit and transform the documents in the editor.

There are two types of integrations that are possible:

- **SharePoint Online** - A new implementation that uses the SharePoint REST API v.2 and it supports OAuth credentials (access tokens). If you need authentication, you must use this type of integration.
- **SharePoint** - The older implementation that was implemented using SharePoint Web Services (now deprecated) and it does NOT support OAuth credentials (access tokens).

Figure 556. SharePoint Connection in Data Source Explorer View



Related Information:
Working with Databases *(on page 2133)*

How to Configure a SharePoint Connection

By default, Oxygen XML Editor contains built-in data source drivers for **SharePoint**. Use this data source to create a connection to a SharePoint server that will be available in the **Data Source Explorer** view or **SharePoint Browser** view *(on page 2197)*.

There are two types of possible SharePoint connections:

- **SharePoint Online** - A new implementation that uses the SharePoint REST API v.2 and it supports OAuth credentials (access tokens). If you need authentication, you must use this type of integration.
- **SharePoint** - The older implementation that was implemented using SharePoint Web Services (now deprecated) and it does NOT support OAuth credentials (access tokens).

SharePoint Online Connection

To configure a SharePoint connection, follow these steps:

1. Open the **Connection** dialog box using one of these methods:
   - Select **New SharePoint Online Connection** from the **Settings** drop-down menu in the **SharePoint Browser** view (or using the quick action *(on page 2197)*).
   - Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Data Sources**. Select **SharePoint Online** in the **Data Sources** pane and in the **Connections** pane, click the **New** button.
2. Enter a unique name for the connection.
3. Make sure **SharePoint Online** is selected in the **Data Source** combo box.
4. Enter the **Tenant URL** for your SharePoint repository and click **OK**.

In the **SharePoint Browser** view *(on page 2197)*, you can select your connection using the **Site** drop-down menu. Then select **Log in with Microsoft account** from the left pane (or user drop-down menu on the right side of the view) to open Microsoft's log in page in your default browser. Once authenticated, your repository content should be displayed in the view. If you have problems with the log-in process, see Troubleshooting SharePoint Online Connections *(on page 2194)*.

Note:
If you are still logged in when you close Oxygen XML Editor, the authentication persists the next time the application is started. If, for some reason, the authentication fails to recover the access token, an error is displayed in the **Results** pane at the bottom of the application. If this happens, you need to re-authenticate Oxygen XML Editor by using the **Log in with Microsoft account** action.

SharePoint Connection (Older Version)

To configure a SharePoint connection, follow these steps:

1. Open the **Connection** dialog box using one of these methods:
   - Select **New SharePoint Connection** from the **Settings** drop-down menu in the **SharePoint Browser** view (or using the quick action *(on page 2197)*).
   - Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Data Sources**. Select **SharePoint** in the **Data Sources** pane and in the **Connections** pane, click the **New** button.
2. Enter a unique name for the connection.
3. Make sure **SharePoint** is selected in the **Data Source** combo box.
4. Fill-in the connection details:
   a. Enter the **SharePoint URL** for your SharePoint repository.
   b. Set the server domain in the **Domain** field. If you are using a SharePoint 365 account, leave this field empty.
   c. Set the user name to access the SharePoint repository in the **User** field.
   d. Set the password to access the SharePoint repository in the **Password** field.
5. Click **OK**.

Troubleshooting SharePoint Online Connections

Allowed SharePoint Online Sites

SharePoint Online sites supported by Oxygen XML Editor have the following syntax:

- `https://tenant.SharePoint.com`
- `https://tenant.SharePoint.com/sites/siteName`
- `https://tenant.SharePoint.com/sites/siteName/subsiteName1/..../subsiteNameK`
- `https://tenant.SharePoint.com/teams/siteName`
- `https://tenant.SharePoint.com/teams/siteName/subsiteName1/..../subsiteNameK`

Authentication Workflow Problems

Once you configure the SharePoint Online Connection *(on page 2193)* and use the *Log in with Microsoft account* action, the action will open the default browser for authentication. If this is the fist time you access this SharePoint site, you will have to Grant Permissions to Oxygen XML Editor *(on page 2195)*.

If the authentication is successful, the browser should display the **Authentication complete** page:

Attention:
If you cannot get past the *This page isn't working* response while using *Google Chrome*, try using a different browser.

Once you go back to Oxygen XML Editor, in the *SharePoint Browser* you should see your username details and be able to browse the repository.

Grant Permissions to Oxygen XML Editor

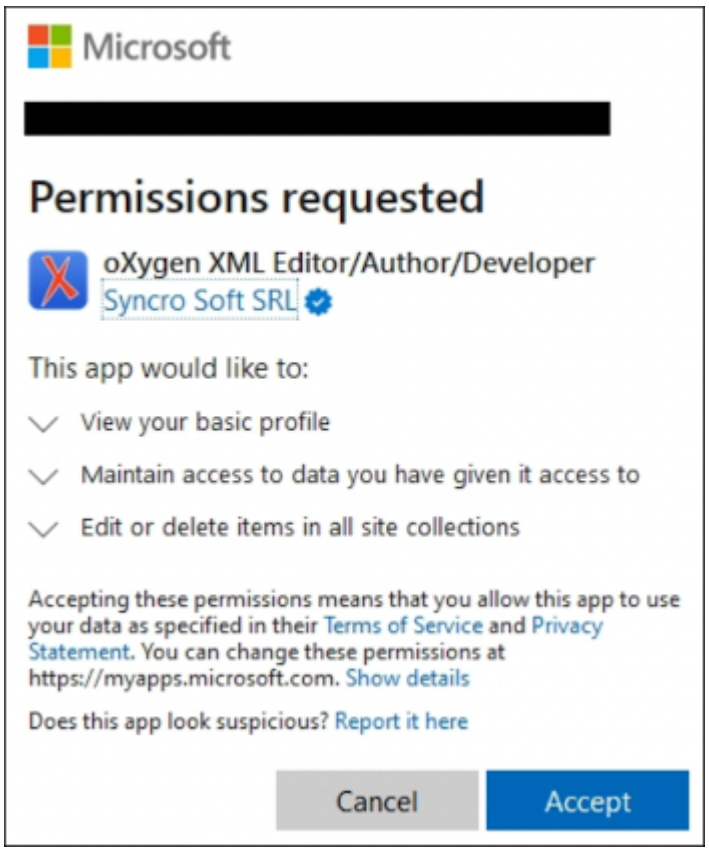
When you first **Log in** and access your **SharePoint** server, you may need to grant **SharePoint Enterprise Application** permissions for the Oxygen XML Editor application to:

- View your basic profile.
- Maintain access to data you have given access to.
- Edit or delete items in all site collections.

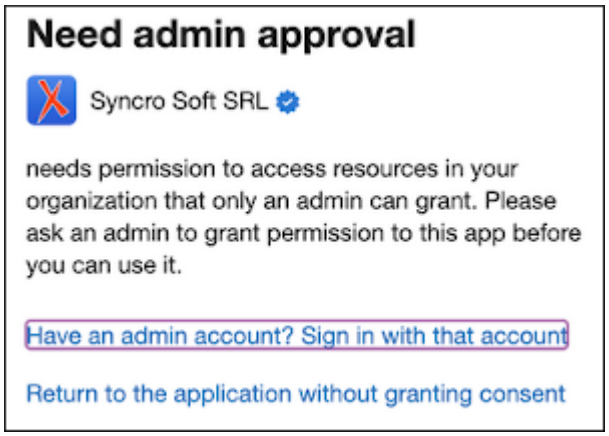
The **Permissions requested** form will appear when you first authenticate to your **SharePoint** server from Oxygen XML Editor.

If you have administrative privileges, you are able to grant permissions directly from the form:

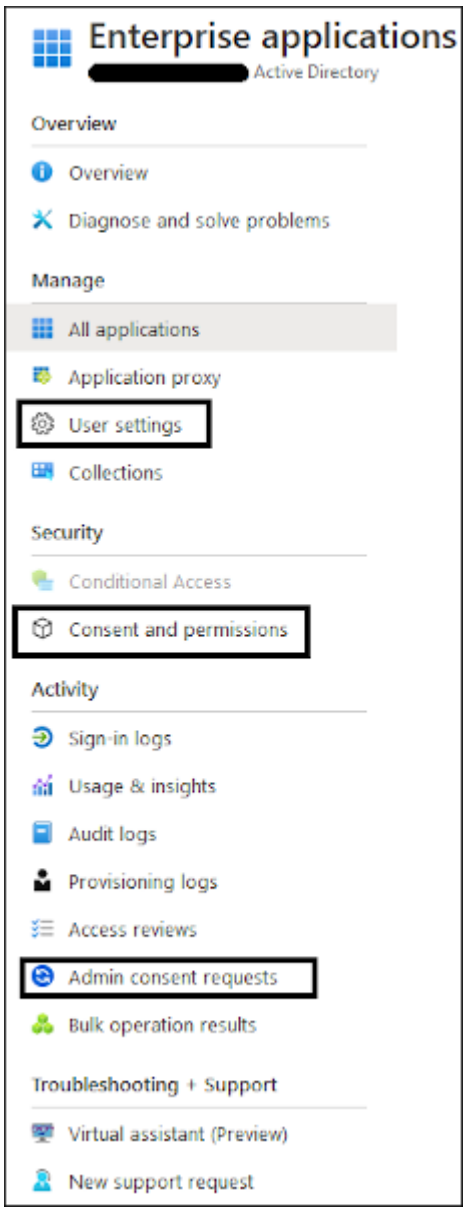
Figure 557. Permissions Requested Form



If you do not have admin rights to give Oxygen XML Editor permissions to access the **SharePoint** server, the **Permissions requested** form will suggest that you contact the administrator for your **SharePoint** account so that they can grant the permissions.



The **SharePoint** global administrator should log in to https://portal.azure.com/, navigate to **Manage Azure Active Directory > Enterprise applications**, and approve the request under the **Admin consent requests** category.



The administrator can also check the **User settings** category and configure the **Users can request admin consent to apps they are unable to consent to** options and policies.

More consent settings can be configured by the admin under the **User consent settings** category.

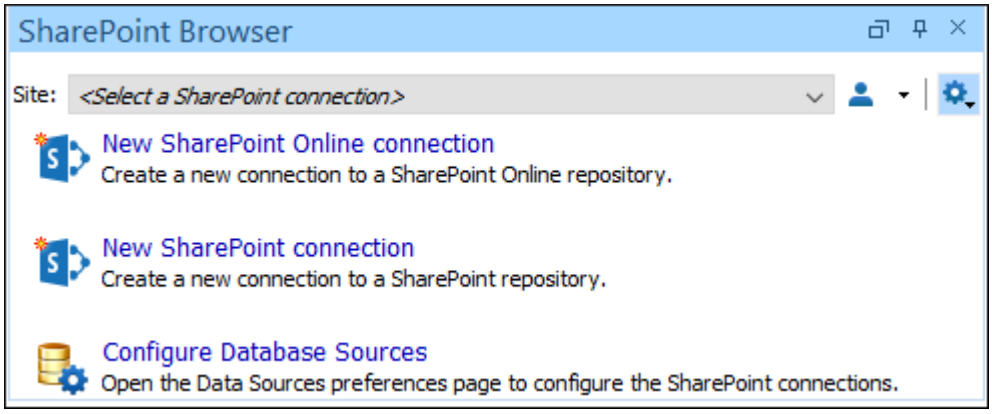
SharePoint Browser View

The **SharePoint Browser** view allows you to connect to a SharePoint repository and perform SharePoint-specific actions on the available resources. To display this view, go to **Window > Show View > SharePoint Browser**.

Getting Started

When you first open the view, it includes some quick actions to help you get connected to your SharePoint repository *(on page 2193)* (these actions are also available in the **Settings** drop-down menu).

Figure 558. SharePoint Browser View Quick Actions



The SharePoint Browser View Interface

The header stripe of the **SharePoint Browser** view includes:

Site drop-down menu

Use this drop-down to select and connect to an already defined SharePoint connection *(on page 2193)*.

User drop-down menu

This drop-down includes

- **Log in with Microsoft account** (if logged out) - Opens the Microsoft login page in your default browser and authenticates Oxygen XML Editor.
- **Log out** (if logged in) - Logs out of your Microsoft account and the authorization between Oxygen XML Editor and Microsoft is revoked.
- **Help** - Opens the online user guide to a topic relevant to the current context.

Settings drop-down menu

This drop-down includes

- **New SharePoint Online Connection** - Opens the **Connection** dialog box with the SharePoint Online data source automatically selected.
- **New SharePoint Connection** - Opens the **Connection** dialog box with the SharePoint (older version) data source automatically selected.
- **Configure Database Sources** - Opens the **Database Sources** preferences page where you can configure your SharePoint connection.
- **Layout** - Use this option to choose the layout for the view. You can choose between: **Automatic**, **Vertical**, and **Horizontal**.

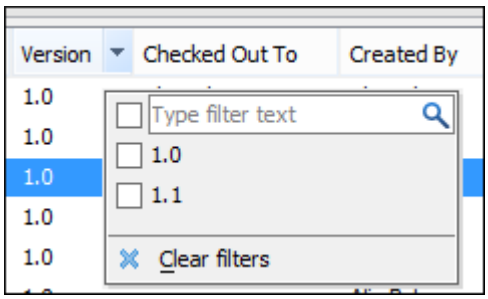
Once you are connected, the view is separated into two panes. The left pane is a navigation area that presents the SharePoint site structure in a tree-like fashion with the following node types:

- **Site**
- **Sub-site**
- **Folders**

When a folder node is selected in the left pane, the right pane displays the contents of the folder (either folders or files).

You can filter and sort the displayed items. To display the available filters of a column, click the filter widget located on the column header. You can apply multiple filters at the same time.

Figure 559. Column Filter



Checking Documents In and Out

To check out a document from the server, right-click the file and select **Check Out**. You can discard the previous checkout operation, making the file available for editing to other users, by selecting **Discard Check Out**.

To check in a document that has been checked out, right-click the file and select **Check In**. For SharePoint Online connections, you only have the option to enter a comment and click the **Check In** button to process it. For SharePoint (older version), you can also choose the check in type (**Minor Version**, **Major Version**, or **Overwrite**).

Related Information:
How to Configure a SharePoint Connection *(on page 2193)*

SharePoint Contextual Menu Actions

While browsing SharePoint connections in the **Data Source Explorer** view *(on page 2133)* or the **SharePoint Browser** view *(on page 2197)*, the following contextual menu actions are available, depending on the type of node:

Connection Nodes (Data Source Explorer view only)

Configure Database Sources

Opens the **Data Sources** preferences page *(on page 285)* where you can configure both data sources and connections.

Log in with Microsoft Account (when not connected)

Opens the Microsoft login page in your default browser and authenticates Oxygen XML Editor.

Disconnect (when connected)

Stops the connection.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Site Nodes / Sub-site Nodes

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

New File or New Document

Creates a new file on the connection, in the current folder.

New Folder

Creates a new folder on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files (Data Source Explorer view only)

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application (Data Source Explorer view only)

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Check Out

Checks out the selected document on the server.

Check In

Checks in the selected document on the server. This action opens the **Check In** dialog box. For SharePoint Online connections, you only have the option to enter a comment and click the **Check In** button to process it.

For SharePoint (older version), the following options are available:

- **Minor Version** - Increments the minor version of the file on the server.
- **Major Version** - Increments the major version of the file on the server.
- **Overwrite** - Overwrites the latest version of the file on the server.
- **Comment** - Allows you to add a comment for a file that you check in.

Discard Check Out

Discards the previous checkout operation, making the file available to other users.

Important:
Due to some API restrictions, the *Discard Checkout* action may not work when SharePoint Online connections are made directly to a sub-site.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

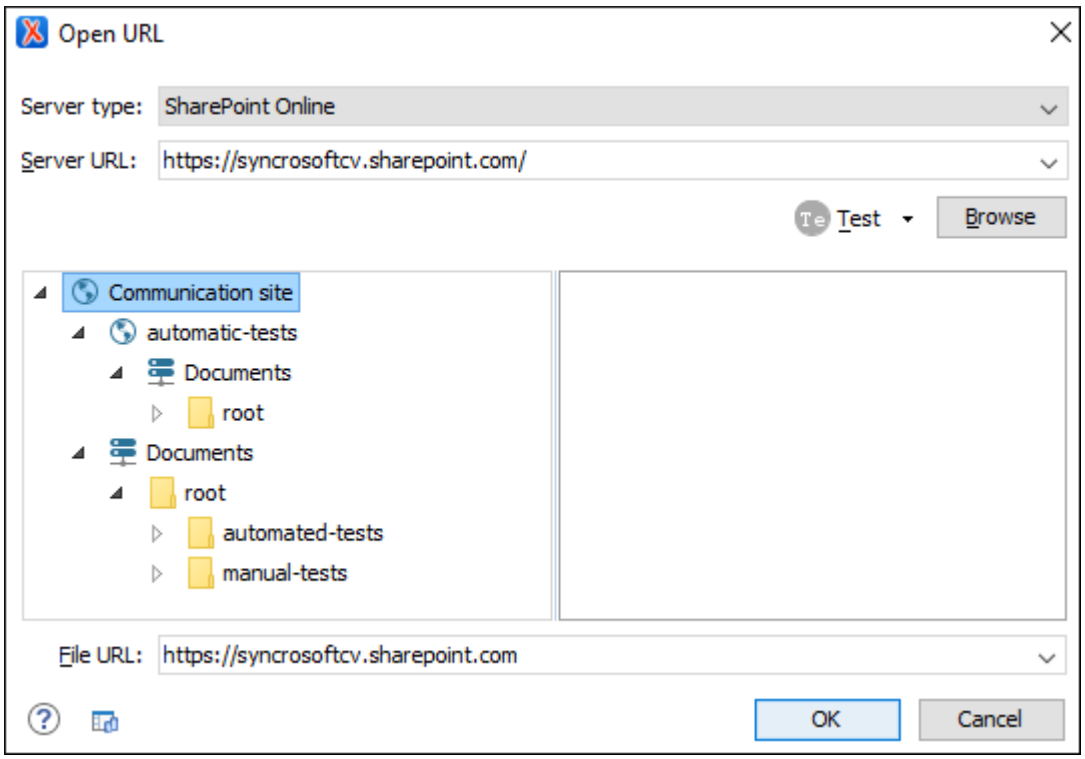
Compare

Compares two selected resources using the **Compare Files** tool *(on page 484)*.

Browsing for Remote Files with SharePoint Online

The **Open URL** dialog box (used for browsing remote files) includes support for connecting to a SharePoint Online server, with controls similar to the **SharePoint Browser** view *(on page 2197)*. To open this dialog box, go to **File >** **Open URL** (or click the **Open URL** toolbar button), then choose the **Browse for remote file** option from the drop-down menu.

Figure 560. Open URL Dialog Box for SharePoint Online



The displayed dialog box is composed of the following:

Server Type

Specifies the type of server (**SharePoint Online** in this case).

Note:
If you select **SharePoint On-Premises**, the controls are similar to those for WebDav and other servers *(on page 397)*.

Server URL

Specifies the protocol (HTTP, HTTPS or FTP) and the host name or IP of the server.

User drop-down menu

This drop-down includes:

- **Log in with Microsoft account** (if logged out) - Opens the Microsoft login page in your default browser and authenticates Oxygen XML Editor.
- **Log out** (if logged in) - Logs out of your Microsoft account and the authorization between Oxygen XML Editor and Microsoft is revoked.
- **Help** - Opens the online user guide to a topic relevant to the current context.

Browse

Use this button to retrieve the data from the server. Once the authentication completes, the files from the server will be available in the dialog box.

File URL

You can use this combo box to directly specify the URL to be opened or saved. This combo box also displays the current selection when the user changes selection by browsing the tree of folders and files on the server.

MS Azure Active Directory Authentication

It is possible to use your MS Azure Active Directory credentials for SharePoint authentication. To configure the application to use your *client ID* and *client secret*, set the following **Oxygen** system properties *(on page 342)*:

- `com.oxygenxml.azure.active.directory.client.id` - Specifies a custom *client ID*.
- `com.oxygenxml.azure.active.directory.client.secret` - Specifies a custom *client secret*.

Your application should allow the following API permissions:

Table 44. API Permissions - Microsoft Graph

Microsoft Graph			
Name	**Type**	**Description**	**Admin consent**
email	Delegated	View users' email address	No
Files.ReadWrite.All	Delegated	Have full access to all files user can access	No

Table 44. API Permissions - Microsoft Graph (continued)

Microsoft Graph			
offline_access	Delegated	Maintain access to data you have given it access to	No
openid	Delegated	Sign users in	No
profile	Delegated	View users' basic profile	No
Sites.ReadWrite.All	Delegated	Edit or delete items in all site collections	No
User.Read	Delegated	Sign in and read user profile	No

Table 45. API Permissions - SharePoint

SharePoint			
Name	**Type**	**Description**	**Admin consent**
AllSites.Read	Delegated	Read items in all site collections	No
AllSites.Write	Delegated	Read and write items in all site collections	No

Notice:
The *Redirect URI* should be set to: `http://localhost/oauth/redirect`

15.

Importing Data

Computer systems and databases contain data in incompatible formats and exchanging data between these systems can be very time consuming. Converting the data to XML can greatly reduce the complexity and create data that can be read by various types of applications.

Oxygen XML Editor offers support for importing text files, MS Excel files, Database Data, and HTML files into XML documents. The XML documents can be further converted into other formats using the Transform features *(on page 1470)*.

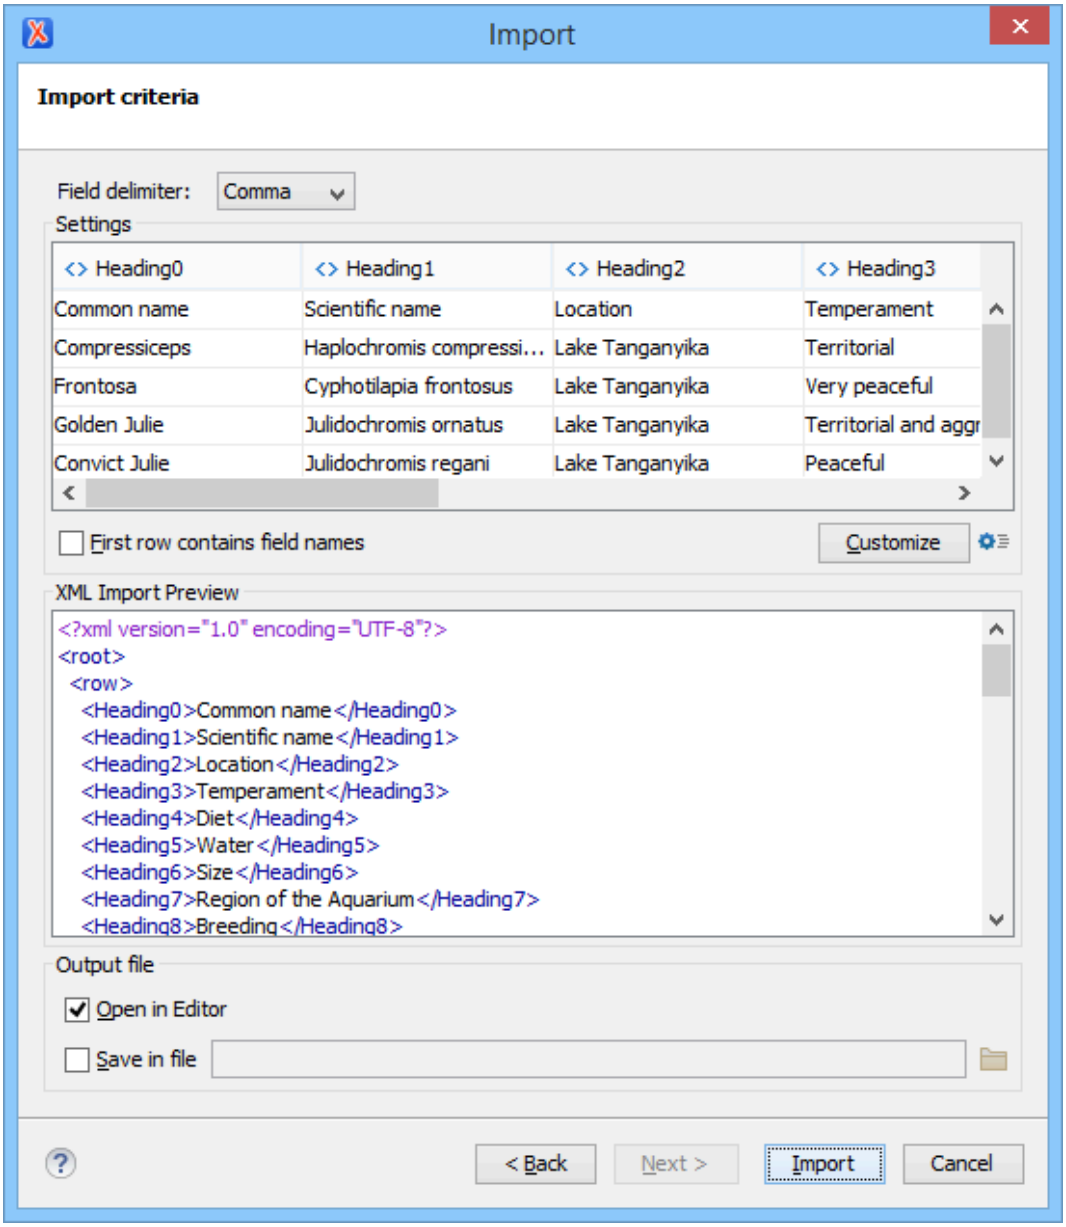
Import from Text Files

Oxygen XML Editor includes the possibility of importing text files (`txt` or `csv` file extensions) as XML documents.

To import a text file into an XML file, follow these steps:

1. Go to **File > Import/Convert > Text File to XML**.
   A **Select text file** dialog box is displayed.
2. Select the URL of the text file (`txt` or `csv` file extensions).
3. Select the encoding of the text file.
4. Click the **Next** button.
   The **Import Criteria** dialog box is displayed.

Figure 561. Import Criteria Dialog Box



5. Configure the settings for the conversion.
   a. Select the **Field delimiter** for the import settings. You can choose between the following: `Comma`, `Semicolon`, `Tab`, `Space`, or `Pipe`.
   b. The **Import settings** section presents the input data in a tabular form. By default, all data items are converted to element content (<> symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (= symbol). Clicking a second time causes the column data to be ignored (× symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.
   c. **First row contains field names** - If this option is selected, the default column headers are replaced (where such information is available) by the content of the first row. In other words, the first row is interpreted as containing the field names. The changes are also visible in the preview panel.

d. **Customize** - This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following options in the drop-down menu: `ELEMENT`, `ATTRIBUTE`, or `SKIPPED`.
e. **Import Settings** - Clicking this button opens the **Import** preferences page *(on page 274)* that allows you to configure more import options.
f. The **XML Import Preview** panel contains an example of what the generated XML document looks like.
g. **Open in editor** - If selected, the new XML document created from the imported text file is opened in the editor.
h. **Save in file** - If selected, the new XML document is saved in the specified path.

6. Click **Import** to generate the XML document.

Import from MS Excel Files

Oxygen XML Editor provides several methods for importing MS Excel files into an XML file. The first method is to use the Oxygen XML Editor **Smart Paste** mechanism *(on page 623)* by simply copying data from Excel and pasting it into a document in **Author** mode (note that this is only supported in DITA, DocBook, TEI, JATS, and XHTML documents). You can also copy data from Excel and paste it into inserted cells in **Grid** mode, but this is a more manual process. If you want to import an entire Excel file, Oxygen XML Editor also offers a configurable import wizard that works with any type of XML document.

Smart Paste Method in Author Mode

If you are importing data into DITA, DocBook, TEI, JATS, or XHTML documents, you can open the Excel spreadsheet in your office application, copy its content, and simply paste it into your document in **Author** mode.

The Oxygen XML Editor **Smart Paste** mechanism *(on page 623)* will convert the pasted content to the equivalent XML markup and considers various pasting solutions to keep the resulting document valid, while preserving the original text styling (such as bold, italics, underline) and formatting (such as lists, tables, paragraphs).

Grid Mode Method

The **Grid** mode in Oxygen XML Editor displays all content in an XML document as a structured grid of nested tables and you can work with the cells in those tables much like you would with any spreadsheet application. When importing Excel data into **Grid** mode, you first need to insert new cells in the particular nested table and then you can paste data from Excel the same as you would in any table or spreadsheet.

1. Copy the particular cells from your Excel spreadsheet that you want to import into an XML file.
2. Switch to **Grid** mode in Oxygen XML Editor.
3. Expand the particular nodes and locate the nested table where you want to insert the copied cells.

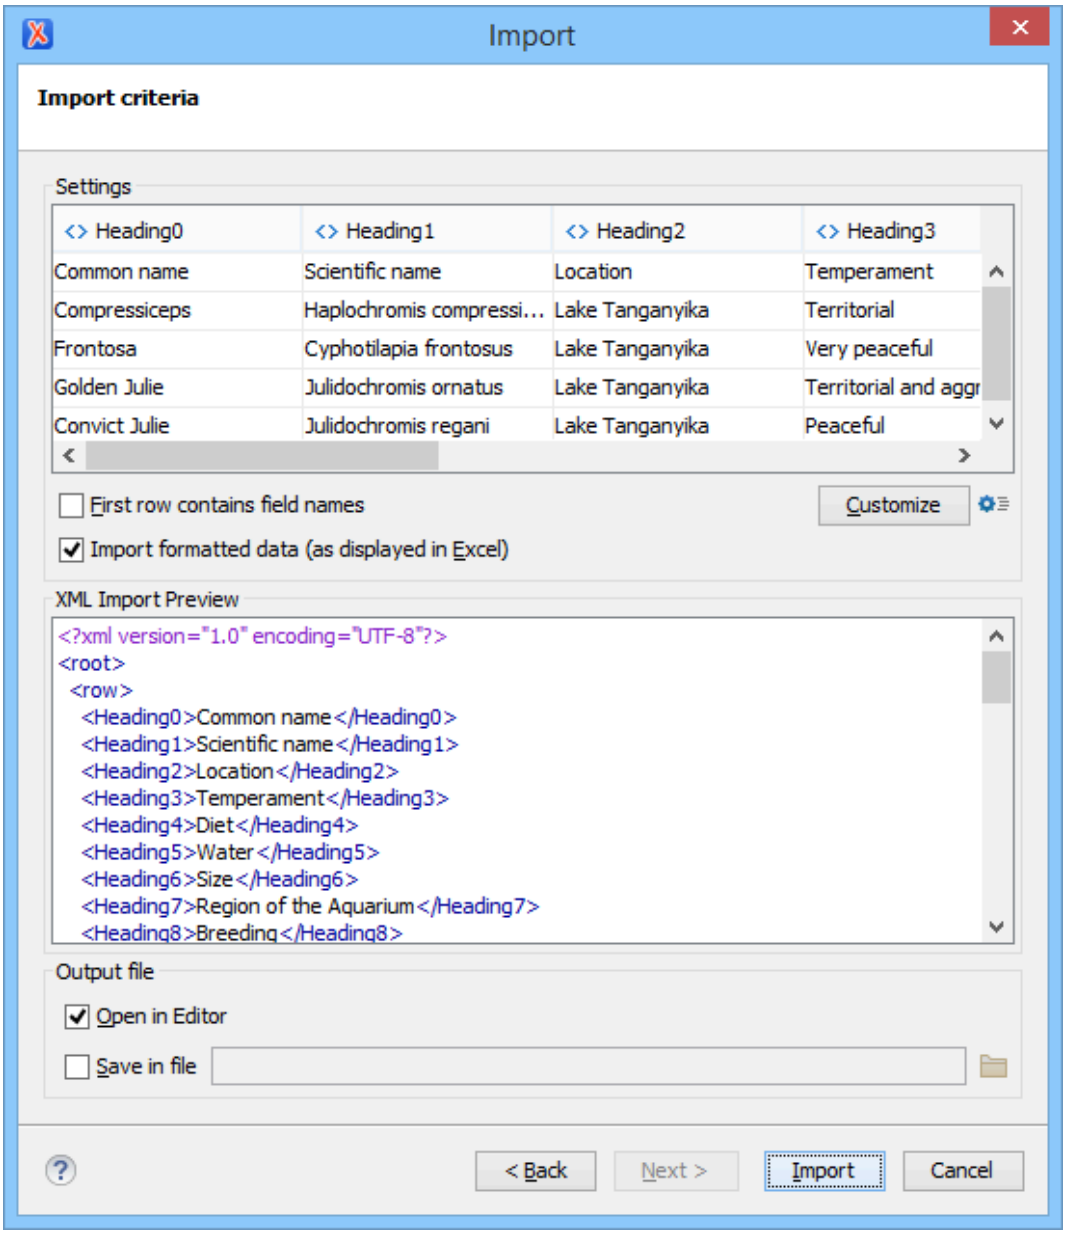
4. Right-click a particular row or column where you want to insert the data and select **Insert row** or **Insert column**, depending on the structure of the copied cells.
5. Paste the copied cells from the clipboard into the newly inserted cells in **Grid** mode.
6. You may need to make some manual adjustments. For example, if the selection of copied cells contained an empty cell, Oxygen XML Editor might ignore that cell.

Import Wizard Method

To use the **Import** wizard to import an Excel file into an XML file, follow these steps:

1. Go to **File > Import/Convert > MS Excel file to XML**.
2. Select the URL of the Excel file. The sheets of the document you are importing are presented in the **Available Sheets** section of this dialog box.
3. Click the **Next** button to proceed to the next stage of the wizard.

Figure 562. Import Wizard



4. Configure the settings for the conversion. This stage of the wizard offers the following options:

   Import settings section

   Presents the input data in a tabular form. By default, all data items are converted to element content (symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (symbol). Clicking a second time causes the column data to be ignored (symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.

   First row contains field names

   If this option is selected, the default column headers are replaced (where such information is available) by the content of the first row. In other words, the first row is interpreted as containing the field names. The changes are also visible in the preview panel.

   Customize

   This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following option in the drop-down menu: `ELEMENT`, `ATTRIBUTE`, or `SKIPPED`.

   Import Settings

   Clicking this button opens the **Import** preferences page *(on page 274)* that allows you to configure more import options.

   Import formatted data (as displayed in Excel)

   If this option is selected, the imported data retains the Excel data formatting (such as the representation of numeric values or dates). If deselected, the data formatting is not imported.

   XML Import Preview panel

   Contains an example of what the generated XML document will look like.

   Open in editor

   If selected, the new XML document created from the imported file is opened in the editor.

   Save in file

   If selected, the new XML document is saved in the specified path.

5. Click **Import** to generate the XML document.

Resources

For more information about exchanging data between Oxygen XML Editor and spreadsheet applications, watch our video demonstration:

https://www.youtube.com/embed/8VwsF58zLkU

Related information

Exporting XML Content to Excel *(on page 597)*

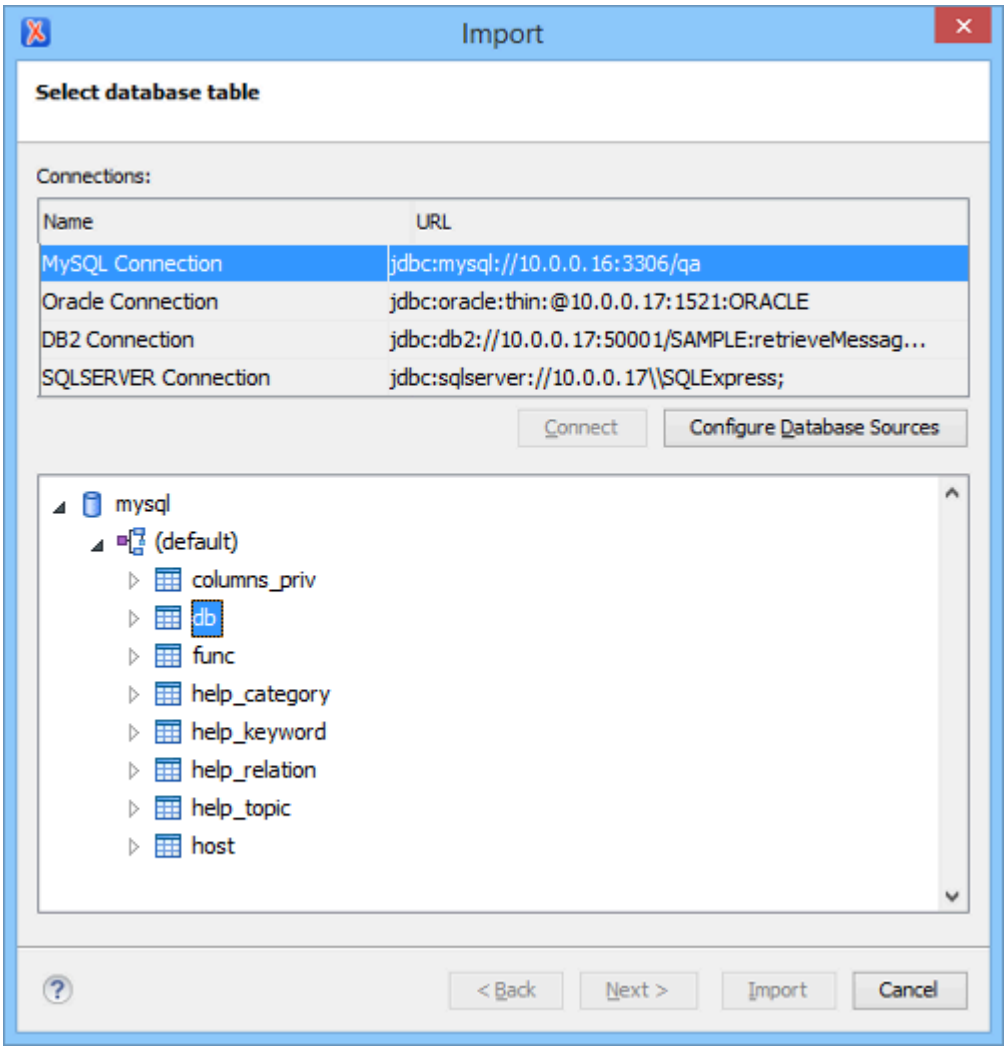
Import Database Data as an XML Document

To import the data from a relational database table as an XML document, follow these steps:

1. Go to **File > Import/Convert > Database Data to XML** to start the **Import** wizard.

   This opens a **Select database table** dialog box that lists all the defined database connections:

   Figure 563. Select Database Table Dialog Box



2. Select the connection to the database that contains the appropriate data.

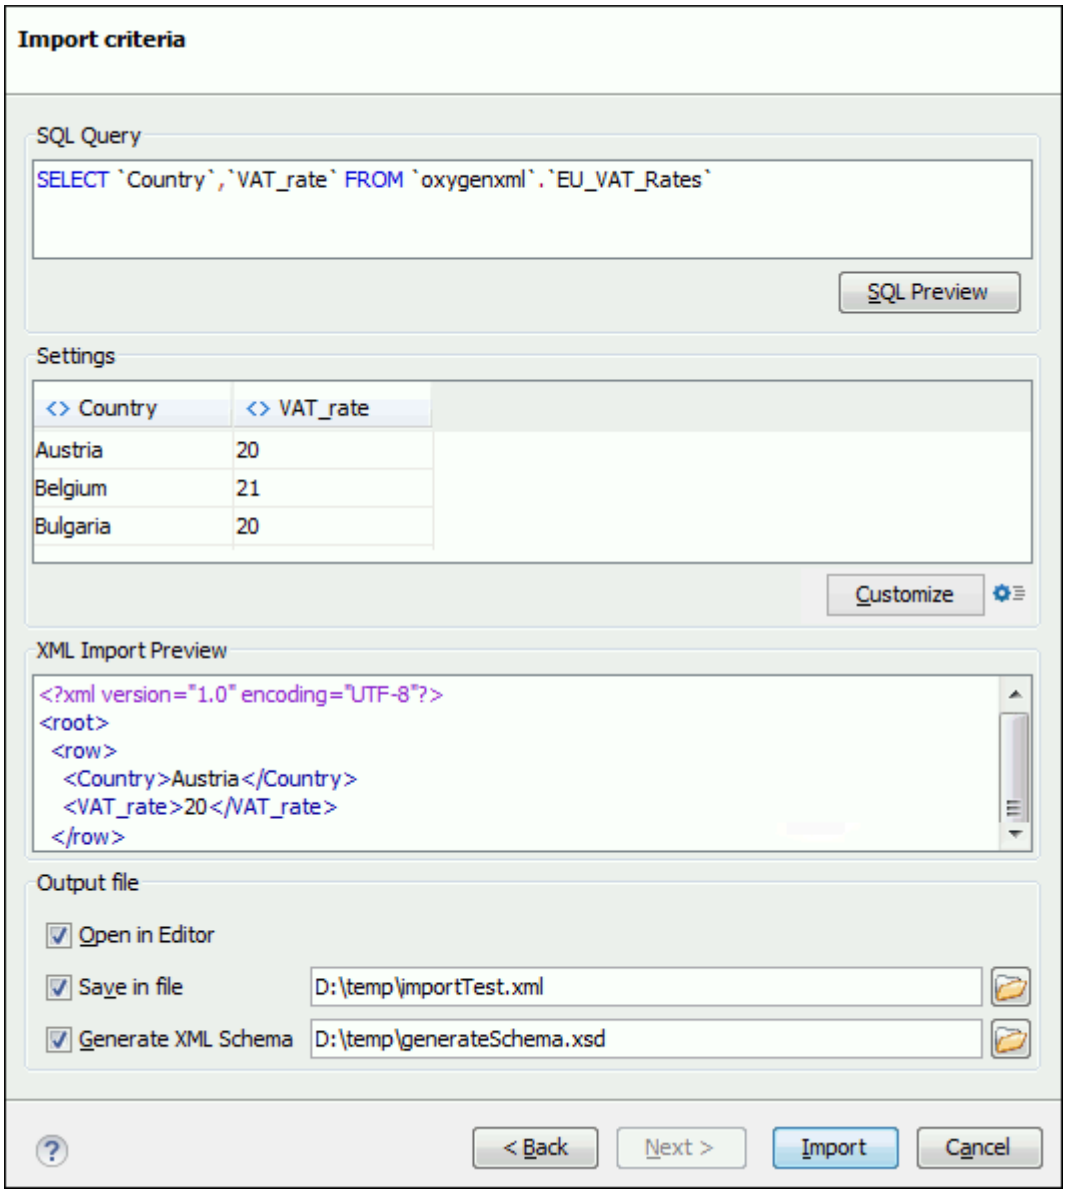
Only connections configured in relational data sources can be used to import data.

3. If you want to edit, delete, or add a data source or connection, click the **Configure Database Sources** button.

   The **Preferences/Data Sources** option page is opened.
4. Click **Connect**.
5. In the list of sources, expand a schema and choose the required table.
6. Click the **Next** button.

   The **Import Criteria** dialog box is opened with a default query string in the **SQL Query** pane.

Figure 564. Import from Database Criteria Dialog Box



7. Configure the settings for the conversion.
   a. **SQL Preview** - If this button is pressed, the **Settings** pane displays the labels that are used in the XML document and the first five lines from the database. By default, all data items are converted to element content (<> symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to

attribute values (symbol). Clicking a second time causes the column data to be ignored (symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.

b. **Customize** - This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following option in the drop-down menu: `ELEMENT`, `ATTRIBUTE`, or `SKIPPED`.

c. **Import Settings** - Clicking this button opens the **Import** preferences page *(on page 274)* that allows you to configure more import options.

d. The **XML Import Preview** panel contains an example of what the generated XML document looks like.

e. **Open in editor** - If selected, the new XML document created from the imported file is opened in the editor.

f. **Save in file** - If selected, the new XML document is saved in the specified path.

g. **Generate XML Schema** - Allows you to specify the path of the generated XML Schema file.

8. Click **Import** to generate the XML document.

Import from HTML Files

Oxygen XML Editor offers two methods for importing HTML files into an XML document. The first method is to simply copy data from an HTML document and paste it into a document in **Author** mode, but this is only supported in DITA, DocBook, TEI, JATS, and XHTML documents. Oxygen XML Editor also offers a configurable import wizard that works with any type of XML document.

Smart Paste Method

If you are importing data into DITA, DocBook, TEI, JATS, or XHTML documents, you can open the HTML document in your web browser, copy its content, and paste it into your document in **Author** mode.

The Oxygen XML Editor **Smart Paste** mechanism *(on page 623)* will convert the pasted content to the equivalent XML markup and considers various pasting solutions to keep the resulting document valid, while preserving the original text styling (such as bold, italics, underline) and formatting (such as lists, tables, paragraphs).

Import Wizard Method

To use the **Import** wizard to import from HTML files, follow these steps:

1. Go to **File > Import/Convert > HTML File to XHTML**. The **Import HTML to XHTML** wizard is displayed.
2. Enter the URL of the HTML document.
3. Select the type of the resulting XHTML document:

- XHTML5
- XHTML 1.0 Transitional
- XHTML 1.0 Strict

4. Click the **OK** button.

Result: The resulting document is an XHTML file containing a DOCTYPE declaration that references the XHTML DTD definition on the Web. The parsed content of the imported file is transformed to XHTML5, XHTML Transitional, or XHTML Strict depending on the option you chose.

Import Content Dynamically

Along with the built-in support for various useful URL protocols (such as HTTP or FTP), Oxygen XML Editor also provides special support for a *convert* protocol that can be used to chain predefined processors to dynamically import content from various sources.

Important:
Starting with version 26, the dynamic conversion protocol is disabled by default. To enable it, you must set the `com.oxygenxml.enable.convert.url.protocol` system property *(on page 350)* to the value of `true`.

A *dynamic conversion URL* chains various processors that can be applied, in sequence, on a target resource and has the following general syntax:

```
convert:/processor=xslt;ss=urn:processors:excel2d.xsl/processor=excel!/urn:files:my.xls
```

The previous example first applies a processor (`excel`) on a target identified by the identifier (`urn:files:sample.xls`) and converts the Excel™ resource to XML. The second applied processor (`xslt`) applies an XSLT stylesheet identified using the identifier (`urn:processors:excel2d.xsl`) over the resulting content from the first applied processor. These identifiers are all mapped to real resources on disk via an *XML catalog* that is configured in the application, as in the following example:

```
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
  <rewriteURI uriStartString="urn:files:" rewritePrefix="./resources/"/>
  <rewriteURI uriStartString="urn:processors:" rewritePrefix="./processors/"/>
</catalog>
```

The target resource part of the conversion URL must always follow the `!/` pattern. It can be any of the following:

- An absolute URL that points to a resource.
- An identifier that will be resolved to an actual resource via the *XML Catalog (on page 3425)* support in the application. In the example above, the **urn:files:sample.xls** target resource is resolved via the *XML catalog*.

- A relative location. This location can only be resolved to an actual resource URL when the application has enough information about the location where the URL is referenced.

  For example, for a *DITA map (on page 3419)* with a `<topicref>` such as:

  ```
  <topicref href="convert:/.../processor=excel!/resources/sample.xls"/>
  ```

  the `resources/sample.xls` path will be resolved relative to the *DITA map* location.

This type of URL can be opened in the application by using the **Open URL** action from the **File** menu. It can also be referenced from existing XML resources via *xi:include* or as a topic reference from a *DITA map*.

A *GitHub* project that contains various dynamic conversion samples for producing DITA content from various sources (and then publishing it) can be found here: https://github.com/oxygenxml/dita-glass.

Conversion Processors

A set of predefined conversion processors is provided in Oxygen XML Editor. Each processor has its own parameters that can be set to control the behavior of the conversion process. All parameters that are resolved to resources are passed through the *XML catalog* mapping.

The following predefined conversion processors are included:

- **`xslt` Processor** - Converts an XML input using the Saxon EE XSLT processor. The `ss` parameter indicates the stylesheet resource to be loaded. All other specified parameters will be set as parameters to the XSLT transformation.

  ```
  convert:/processor=xslt;ss=urn:processors:convert.xsl;p1=v1!/urn:files:sample.xml
  ```

- **`xquery` Processor** - Converts an XML input using the Saxon EE XQuery processor. The `ss` parameter indicates the XQuery script to be loaded. All other specified parameters will be set as parameters to the XSLT transformation.

  ```
  convert:/processor=xquery;ss=urn:processors:convert.xquery;p1=v1!/urn:files:sample.xml
  ```

- **`excel` Processor** - Converts an Excel™ input to an XML format that can later be converted by other piped processors. It has a single parameter `sn`, which indicates the name of the sheet that needs to be converted. If this parameter is missing, the XML will contain the combined content of all sheets included in the Excel™ document.

  ```
  convert:/processor=excel;sn=test!/urn:files:sample.xls
  ```

- **`java` Processor** - Converts an input to another format by applying a specific Java method. The `jars` parameter is a comma-separated list of *JAR (on page 3420)* libraries, or folders that libraries will be loaded from. The `ccn` parameter is the fully qualified name of the conversion class that will be instantiated. The conversion class needs to have a method with the following signature:

  ```
  public void convert(String systemID, String originalSourceSystemID,
  InputStream is, OutputStream os, LinkedHashMap<String, String> properties)
  throws IOException
  ```

```
convert:/processor=java;jars=libs;ccn=test.JavaToXML!/
urn:files:java/WSEditorBase.java
```

- **`js` Processor** - Converts an input to another format by applying a JavaScript method. The `js` parameter indicates the script that will be used. The `fn` parameter is the name of the method that will be called from the script. The method must take a string as an argument and return a string. If any of the parameters are missing, an error is thrown and the conversion stops.

  ```
  convert:/processor=js;js=urn:processors:md.js;fn=convertExternal!/urn:files:sample.md
  ```

- **`json` Processor** - Converts a JSON input to XML. It has no parameters.

  ```
  convert:/processor=json!/urn:files:personal.json
  ```

- **`xhtml` Processor** - Converts HTML content to well-formed XHTML. It has no parameters.

  ```
  convert:/processor=xhtml!/urn:files:test.html
  ```

- **`wrap` Processor** - Wraps content in a tag name making it well-formed XML. The `rn` parameter indicates the name of the root tag to use. By default, it is `wrapper`. The `encoding` parameter specifies the encoding that should be used to read the content. By default, it is `UTF8`. As an example, this processor can be used if you want to process a comma-separated values file with an XSLT stylesheet to produce XML content. The CSV file is first wrapped as well-formed XML, which is then processed with an `xslt` processor.

  ```
  convert:/processor=wrap!/urn:files:test.csv
  ```

- **`cache` Processor** - Caches the converted content obtained from the original document to a temporary file. The cache will be used on subsequent uses of the same URL, thus increasing the speed for the application returning the converted content. If the original URL points to the local disk, the cache will be automatically invalidated when the original file content gets modified. Otherwise, if the original URL points to a remote resource, the cache will need to be invalidated by reloading (**Reload (F5)** from the toolbar) the URL content that is opened in the editor.

  ```
  convert:/processor=cache/processor=xslt;…..!/urn:files:test.csv
  ```

Reverse Conversion Processors

All processors defined above can also be used for saving content back to the target resource if they are defined in the URL as reverse processors. Reverse processors are evaluated right to left. These reverse processors allow *round-tripping* content to and from the target resource.

As an example, the following URL converts HTML to DITA when the URL is opened using the `h2d.xsl` stylesheet and converts DITA to HTML when the content is saved in the application using the `d2h.xsl` stylesheet.

```
convert:/processor=xslt;ss=h2d.xsl/rprocessor=xslt;ss=d2h.xsl!/urn:files:sample.html
```

Important:

If you are publishing a *DITA map* that has such conversion URL references inside, you need to edit the transformation scenario and set the value of the parameter *fix.external.refs.com.oxygenxml* to **true**. This will instruct Oxygen XML Editor to resolve such references during a special pre-processing stage. Depending on the conversion, you may also require additional libraries to be added using the **Libaries** button in the **Advanced** tab of the transformation scenario.

Related Information:

https://github.com/oxygenxml/dita-glass

16.

Debugging XSLT Stylesheets and XQuery Documents

Oxygen XML Editor includes a powerful debugging interface that helps you to detect and solve problems with XSLT and XQuery transformations.

XSLT Debugger Perspective

The **XSLT Debugger** *perspective (on page 3422)* allows you to detect problems in an XSLT transformation by executing the process step by step. To switch the focus to this *perspective*, select the  **XSLT Debugger** button in the top-right corner of the interface or **Window > Open perspective > XSLT Debugger**.

XQuery Debugger Perspective

The **XQuery Debugger** *perspective (on page 3422)* allows you to detect problems in an XQuery transformation process by executing the process step by step in a controlled environment and inspecting the information provided in the special views. To switch the focus to this *perspective*, select the  **XQuery Debugger** button in the top-right corner of the interface or **Window > Open perspective > XQuery Debugger**.

XSLT/XQuery Debugging Overview

The **XSLT Debugger** and **XQuery Debugger** *perspectives (on page 3422)* allows you to test and debug XSLT 1.0 / 2.0 / 3.0 stylesheets and XQuery 1.0 / 3.0 documents including complex XPath 2.0 / 3.0 expressions. The interface presents simultaneous views of the source XML document, the XSLT/XQuery document and the result document. As you go step by step through the XSLT/XQuery document the corresponding output is generated step by step, and the corresponding position in the XML file is highlighted. At the same time, special views provide various types of debugging information and events useful to understand the transformation process.

The following set of features allow you to test and solve XSLT/XQuery problems:

- Support for XSLT 1.0 stylesheets (using Saxon 6.5.5 and Xalan XSLT engines), XSLT 2.0 / 3.0 stylesheets and XPath 2.0 / 3.0 expressions that are included in the stylesheets (using Saxon 12.3 XSLT engine) and XQuery 1.0 / 3.0 (using Saxon 12.3 XQuery engine).
- Stepping capabilities: step in, step over, step out, run, run to cursor, run to end, pause, stop.
- Output to source mapping between every line of output and the instruction element / source context that generated it.
- *Breakpoints (on page 2240)* on both source and XSLT/XQuery documents.
- Call stack on both source and XSLT/XQuery documents.
- Trace history on both source and XSLT/XQuery documents.
- Support for XPath expression evaluation during debugging.
- Step into imported/included stylesheets as well as included source entities.

- Available templates and hits count.
- Variables view.
- Dynamic output generation.

Resources

For even more information, watch our video demonstration:

https://www.youtube.com/embed/m9d8c4V-LJw

Debugger Layout

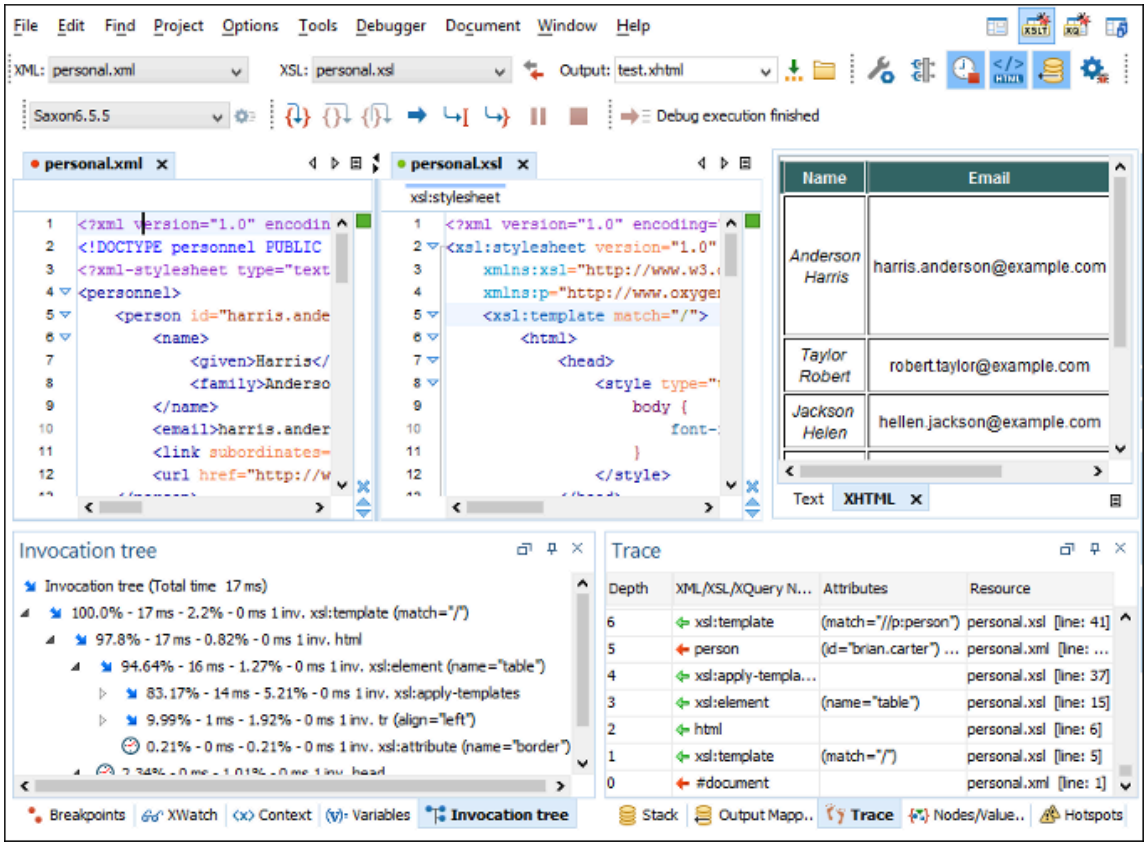
The XML and XSL files are displayed in **Text** mode *(on page 526)*. The other modes (**Author** mode *(on page 363)*, **Grid** mode *(on page 363)*) are available only in the **Editor** *perspective (on page 353)*.

The **XSLT/XQuery Debugger** *perspective (on page 3422)* contains the following components:

- **Source Document View (XML)** - Displays and allows the editing of XML files (documents).
- **XSLT/XQuery Document View (XSLT/XQuery)** - Displays and allows the editing of XSL files (stylesheets) or XQuery documents.
- **Output View** - Displays the output that results from inputting a document (XML) and a stylesheet (XSL) or XQuery document in the transformer. The transformation result is written dynamically while the transformation is processed (using the **Run** button on the Control toolbar *(on page 2222)*). Several actions are available in the contextual menu for this view, including **Find/Replace**, **Copy**, and **Format and Indent**. There are two types of output views: a **Text** view (with XML syntax highlights) and **XHTML** view. For large outputs, the XHTML view can be disabled (see Debugger Settings *(on page 265)*).
- **Control Toolbar** *(on page 2219)* - Contains a variety of actions to help you configure and control the debugging process.
- **Information Views** *(on page 2223)* - The information views at the bottom of the editor display various types of information to help you understand the transformation process.

Tip:
The **Output** view and the various other information views are dockable *(on page 3418)* so that you can configure the workspace according to your preferences.

Figure 565. Debugger Interface



XML documents and XSL stylesheets or XQuery documents that were opened in the **Editor** *perspective (on page 3422)* are automatically sorted into the first two panes. When multiple files of each type are opened, the individual documents and stylesheets are separated using the familiar tab management system that you are used to in the **Editor** *perspective*. Selecting a tab brings the document or stylesheet into focus and enables editing without the need to go back to the **Editor** *perspective*.

In Debugger mode, the normal editor toolbar is not available. However, functions are still accessible from the **Document** menu and the contextual menus.

Bookmarks (on page 529) are replaced in the **Debugger** *perspective* by breakpoints *(on page 2240)*.

During debugging, the current execution node is highlighted in both document (XML) and XSLT/XQuery views.

Related Information:

Steps in a Typical Debugging Process *(on page 2236)*

Identify the XSLT / XQuery Expression that Generated Particular Output *(on page 2237)*

Supported Processors for XSLT / XQuery Debugging *(on page 2247)*

Performance Profiling of XSLT Stylesheets and XQuery Documents *(on page 2241)*

Control Toolbar

The **Control** toolbar contains all the actions that you need to configure and control the debugging process. The following actions are described as they appear in the toolbar from left to right.

Figure 566. Control Toolbar

XML source selector

The current selection represents the source document used as input by the transformation engine. The selection list contains all open files (XML files being emphasized). This option allows you to use other file types also as source documents. In an XQuery debugging session this selection field can be set to the default value `NONE`, because usually XQuery documents do not require an input source.

XSL / XQuery selector

The current selection represents the stylesheet or XQuery document to be used by the transformation engine. The selection list contains all open files (XSLT / XQuery files being emphasized).

Link with editor

When selected, the XML and XSLT/XQuery selectors display the names of the files open in the central editor panels. This button is toggled off by default.

Output selector

The selection represents the output file specified in the associated transformation scenario. You can specify the path by using the text field, the **Insert Editor Variables** *(on page 332)* button, or the **Browse** button.

Configure parameters

Opens a dialog box that allows you to configure the XSLT / XQuery parameters to be used by the transformation.

Edit extensions

Allows you to add and remove the Java classes and *JARS (on page 3420)* used as XSLT extensions.

/ Turn on/off profiling

Enables / Disables current transformation profiling.

Enable XHTML output

Enables the rendering of the output in the **XHTML** output view *(on page 2218)* during the transformation process. For performance issues, disable XHTML output when working with very large files. Note that only XHTML conformant documents can be rendered by this view. To view the output result of other formats, such as HTML, save the **Text output** area to a file and use an external browser for viewing.

When starting a debug session from the **Editor** *perspective (on page 3422)* by using the **Debug Scenario** action, the state of this toolbar button reflects the state of the **Show as XHTML** output option from the scenario.

Turn on/off output to source mapping

Enables or disables the output to source mapping between every line of output and the instruction element / source context that generated it.

Debugger preferences

Quick link to Debugger preferences page *(on page 265)*.

XSLT / XQuery engine selector

Lists the processors available for debugging XSLT and XQuery transformations *(on page 2247)*.

XSLT / XQuery engine advanced options

If Saxon HE/PE/EE is selected, you can click this button to open the Advanced Saxon Transformation Options page *(on page 1509)*.

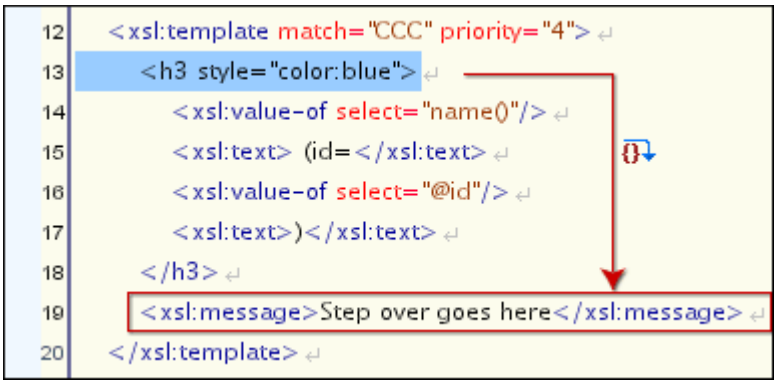
Step into

Starts the debugging process and runs until the next instruction is encountered.

Step over

Run until the current instruction and its sub-instructions are over. Usually this will advance to the next sibling instruction.

Figure 567. Step over



Step out

Run until the parent of the current instruction is over. Usually this will advance to the next sibling of the parent instruction.

Figure 568. Step out

Run Shift + F5

Starts the debugging process. The execution of the process is paused when a breakpoint *(on page 2224)* is encountered or the transformation ends.

Run to cursor

Starts the debugging process and runs until one of the following conditions occur: the line of cursor is reached, a valid *breakpoint (on page 2240)* is reached or the execution ends.

Run to end

Runs the transformation until the end, without taking into account enabled *breakpoints (on page 2240)*, if any.

Pause

Request to pause the current transformation as soon as possible.

Stop

Request to stop the current transformation without completing its execution.

Show current execution nodes

Reveals the current debugger context showing both the current instruction and the current node in the XML source. Possible displayed states:

- Entering ( ) or leaving ( ) an XML execution node.
- Entering ( ) or leaving ( ) an XSL execution node.
- Entering ( ) or leaving ( ) an XPath execution node.

Note:
When you set a MarkLogic server as a processor, the **Show current execution nodes** button is named **Refresh current session context from server**. Click this button to refresh the information in all the views.

Note:
For some XSLT processors (Saxon-HE/PE/EE), the debugger could be configured to step into the XPath expressions affecting the behavior of the following debugger actions: **Step into**, **Step over** or **Step Out**.

Related information
Advanced Saxon HE/PE/EE XQuery Transformation Options *(on page 1523)*

Debugging Information Views

The information views at the bottom of the editor is comprised of two panes that are used to display various types of information used to understand the transformation process. For each information type there is a corresponding tab. While running a transformation, relevant events are displayed in the various information views. This enables the developer to obtain a clear view of the transformation progress. By using the debug controls, developers can easily isolate parts of stylesheet. Therefore, they may be more easily understood and modified.

The information types include the following:

Left side information views

- **Breakpoints** view *(on page 2224)*
- **XWatch** view *(on page 2226)*
- **Context** view *(on page 2225)*
- **Messages** view *(on page 2227)* (XSLT only)
- **Variables** view *(on page 2234)*
- **Invocation Tree** view *(on page 2243)*

Right side information views

- **Stack** view *(on page 2228)*
- **Output Mapping Stack** view *(on page 2229)*
- **Trace** view *(on page 2231)*
- **Templates** view *(on page 2232)* (XSLT only)
- **Nodes/Values Set** view *(on page 2233)*
- **Hotspots** view *(on page 2244)*

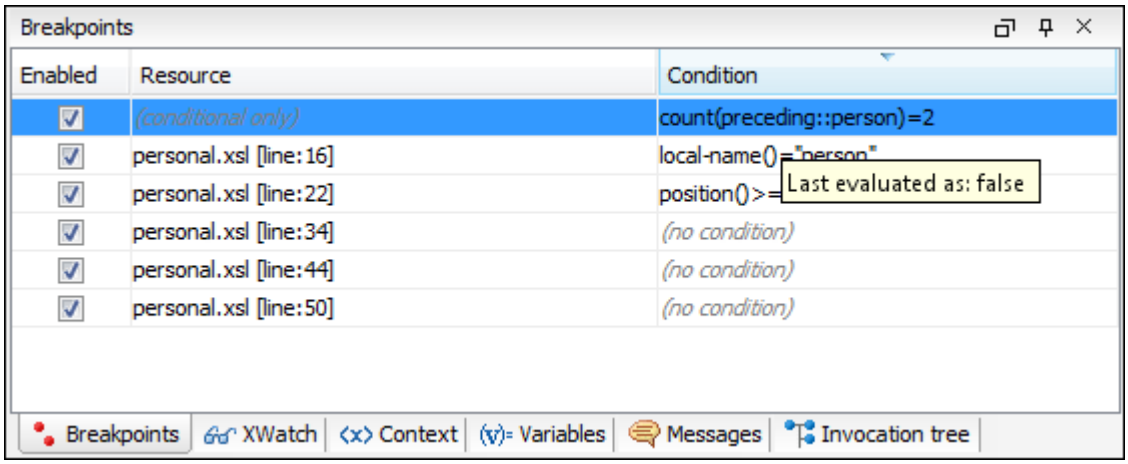
Tip:
The information views are dockable *(on page 3418)* so that you can configure the workspace according to your preferences.

Breakpoints View

The **Breakpoints** view lists all *breakpoints (on page 2240)* that are set on open documents. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu. *Breakpoints* can be inserted *(on page 2241)* in the XML source document or the XSLT/XQuery document in debugging sessions.

Once you insert a *breakpoint*, it is automatically added to the list in the **Breakpoints** view and you can edit its associated *condition*. A *breakpoint* can have an associated break condition that represents an XPath expression evaluated in the current debugger context. For them to be processed, their evaluation result should be a boolean value. A *breakpoint* with an associated condition only stops the execution of the Debugger if the *breakpoint condition* is evaluated as **true**.

Figure 569. Breakpoints View



The **Breakpoints** view contains the following columns:

- **Enabled** - If selected, the current condition is evaluated and taken into account.
- **Resource** - Resource file and number of the line where the *breakpoint* is set. The Entire path of resource file is available as tooltip.
- **Condition** - XSLT/XQuery expression to be evaluated during debugging. The expression will be evaluated at every debug step.

Clicking a record highlights the *breakpoint* line in the document.

Note:
The *breakpoints* list is not deleted at the end of a transformation (it is preserved between debugging sessions).

The following actions are available in the contextual menu of the table:

Go to

Moves the cursor to the source of the *breakpoint*.

Run to Breakpoint

Runs the debugger up to the point of this particular *breakpoint* and ignores the others (regardless of whether they were previously enabled or disabled).

Enable

Enables the *breakpoint*.

Disable

Disables the *breakpoint*. A disabled *breakpoint* will not be evaluated by the Debugger.

Add

Allows you to add a new *breakpoint* and *breakpoint condition*.

Edit

Allows you to edit an existing *breakpoint*.

Remove

Deletes the selected *breakpoint*.

Enable all

Enables all *breakpoints*.

Disable all

Disables all *breakpoints*.

Remove all

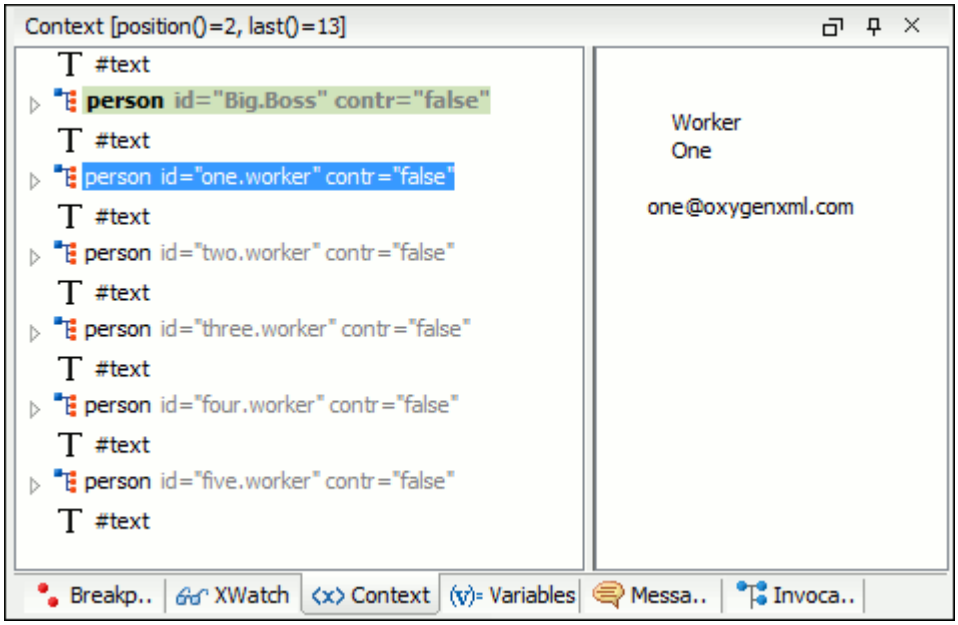
Removes all *breakpoints*.

Related Information:
Using Breakpoints *(on page 2240)*

Context View

The context node is valid only for XSLT debugging sessions and is a source node corresponding to the XSL expression that is evaluated. It is also called the context of execution. The context node implicitly changes as the processor hits various steps (at the point where XPath expressions are evaluated). This node has the same value as evaluating '.' (dot) XPath expression in **XWatch** view *(on page 2226)*. The value of the context node is presented as a tree in the **Context** view. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 570. Context node view



The context nodes are presented in a tree-like fashion. Nodes from a defined namespace bound to a prefix are displayed using the qualified name. If the namespace is not bound to a prefix, the namespace URI is presented before the node name. The value of the selected attribute or node is displayed in the right side panel. The **Context** view also presents the current mode of the XSLT processor if this mode differs from the default one.

The title bar displays the current element index and the number of elements that compose the current context (this information is not available if you choose Xalan or Saxon 6 as processing engine).

XPath Watch (XWatch) View

The **XWatch** view shows XPath expressions evaluated during the debugging process. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Expressions are evaluated dynamically as the processor changes its source context. When you type an XPath expression in the **Expression** column, Oxygen XML Editor supports you with syntax highlight and content completion assistance *(on page 907)*.

Figure 571. XPath Watch View

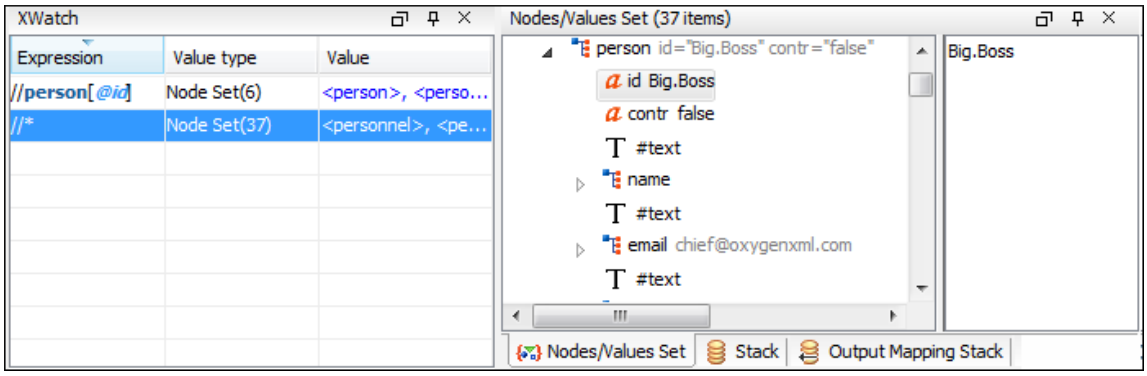


Table 46. XWatch columns

Column	Description
Expression	XPath expression to be evaluated (XPath 1.0 or 2.0 / 3.0 compliant).
Value	Result of XPath expression evaluation. Value has a type (see the possible values *(on page 2234)* in the Variables View *(on page 2234)*) section. For *Node Set* results, the number of nodes in the set is shown in parenthesis.

Important:
Notes about working with the **XWatch** view:

- Expressions that reference variable names are not evaluated.
- The expression list is not deleted at the end of the transformation (it is preserved between debugging sessions).
- To insert a new expression, click the first empty line of the **Expression** column and start typing. As an alternative, right-click and select the **Add** action. Press **Enter** on the cell to add and evaluate.
- To delete an expression, click its **Expression** column and delete its content. As an alternative, right-click and select the **Remove** action. Press **Enter** on the cell to commit changes.
- If the expression result type is a *Node Set*, click it (**Value** column) and its value is displayed in the **Nodes/Values Set** view *(on page 2233)*.
- The **Copy**, **Add**, **Remove** and **Remove All** actions are available in every row's contextual menu.

Messages View

Using an **xsl:message** instruction is one way to signal special situations encountered during transformation as well as a raw way of doing the debugging. The **Messages** view is available only for XSLT debugging sessions and shows all `xsl:message` calls executed by the XSLT processor during transformation. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 572. Messages View

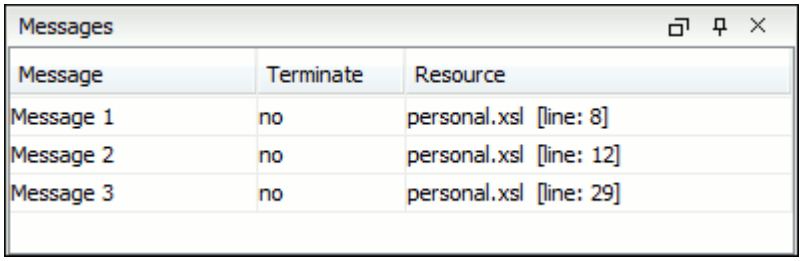

Table 47. Messages columns

Column	Description
Message	Message content.
Terminate	Signals whether or not the processor terminates the transformation once it encounters the message (yes/no respectively).
Resource	Resource file where *xsl:message* instruction is defined and the message line number. The complete path of the resource is available as tooltip.

The following actions are available in the contextual menu:

Go to

Highlight the XSL fragment that generated the message.

Copy

Copies to clipboard message details (system ID, severity info, description, start location, terminate state).

Clear all

Removes all messages from the view.

Important:

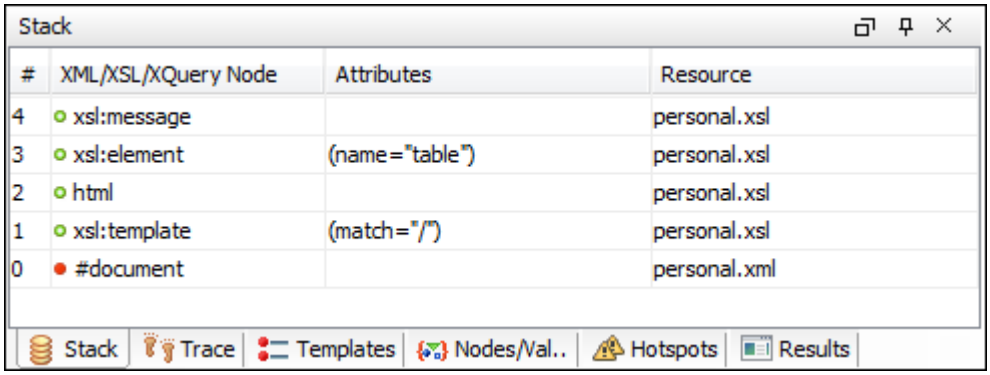
- Clicking a record from the table highlights the `xsl:message` declaration line.
- Message table values can be sorted by clicking the corresponding column header. Clicking the column header switches the sorting order between: ascending, descending, no sort.

Stack View

The **Stack** view shows the current execution stack of both source and XSLT/XQuery nodes. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

During the transformation, two stacks are managed. One for source nodes being processed and the other for XSLT/XQuery nodes being processed. Oxygen XML Editor shows both node types in one common stack. The source (XML) nodes are preceded by a red color icon while XSLT/XQuery nodes are preceded by a green color icon. The advantage of this approach is that you can always see the source scope on which an XSLT/XQuery instruction is executed (the last red color node on the stack). The stack is oriented upside down.

Figure 573. Stack View



The contextual menu contains one action: **Go to**, which moves the selection in the editor panel to the line containing the XSLT element that is displayed on the selected line from the view.

Table 48. Stack Columns

Column	Description
#	Order number, represents the depth of the node (0 is the stack base).
XML/XSLT/XQuery Node	Node from source or stylesheet document currently being processed. One particular stack node is the document root, noted as **#document**.
Attributes	Attributes of the node (a list of *id="value"* pairs).
Resource	Resource file where the node is located. The entire path is available as tooltip.

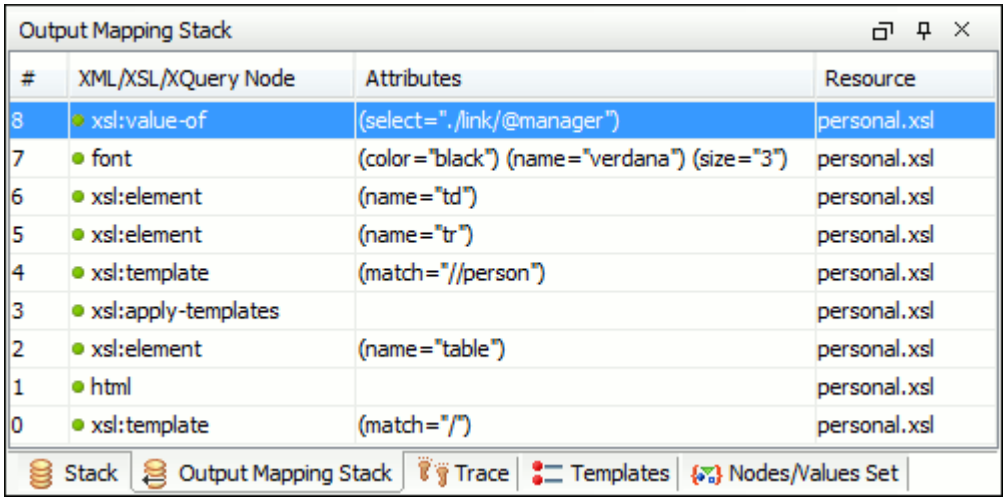
Important:
Remarks:

- Clicking a record from the stack highlights that node's location inside resource.
- Using Saxon, the stylesheet elements are qualified with XSL proxy, while using Xalan you only see their names. (example: `xsl:template` using Saxon and `template` using Xalan).
- Only the Saxon processor shows element attributes.
- The Xalan processor shows also the built-in rules.

Output Mapping Stack View

The **Output Mapping Stack** view displays context data *(on page 2237)* and presents the XSLT templates/XQuery elements that generated specific areas of the output. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 574. Output Mapping Stack view



The **Go to** action of the contextual menu takes you to the line that contains the XSLT element displayed in the **Output Mapping Stack** view.

Table 49. Output Mapping Stack Columns

Column	Description
#	The order number in the stack of XSLT templates/XQuery elements. Number 0 corresponds to the bottom of the stack in the status of the XSLT/XQuery processor. The highest number corresponds to the top of the stack.
XSL/XQuery Node	The name of an XSLT template/XQuery element that participated in the generation of the selected output area.
Attributes	The attributes of the XSLT template/XQuery node.
Resource	The name of the file containing the XSLT template/XQuery element.

Important:

Remarks:

- Clicking a record highlights that XSLT template definition/XQuery element inside the resource (XSLT stylesheet file/XQuery file).
- Saxon only shows the applied XSLT templates having at least one hit from the processor. Xalan shows all defined XSLT templates, with or without hits.
- The table can be sorted by clicking the corresponding column header. When clicking a column header the sorting order switches between: ascending, descending, no sort.
- Xalan shows also the built-in XSLT rules.

Related Information:

Identify the XSLT / XQuery Expression that Generated Particular Output *(on page 2237)*
Stack View *(on page 2228)*
Trace View *(on page 2231)*
Templates View *(on page 2232)*

Trace View

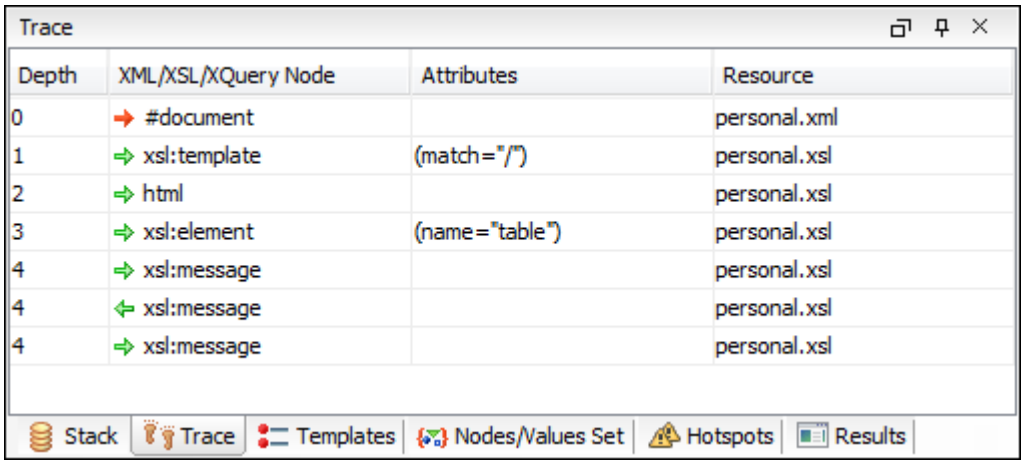
Usually, the XSLT/XQuery processors signal the following events during transformation:

- - Entering a source (XML) node.
- - Leaving a source (XML) node.
- - Entering an XSLT/XQuery node.
- - Leaving an XSLT/XQuery node.

The **Trace** view catches all of these events, so you can see how the process evolved. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

The red icon lines denote source nodes while the green icon lines denote XSLT/XQuery nodes. It is possible to save the element trace in a structured XML document (using the **Export to XML** action in the contextual menu). Thus, you have the possibility of comparing the trace results from multiple debug sessions.

Figure 575. Trace History View



The contextual menu contains the following actions:

Go to

Moves the selection in the editor panel to the line containing the XSLT element or XML element that is displayed on the selected line from the view;

Export to XML

Saves the entire trace list in XML format.

Table 50. Trace History Columns

Column	Description
Depth	Shows you how deep the node is nested in the XML or stylesheet structure. The bigger the number, the more nested the node is. A depth 0 node is the document root.
XML/XSLT/XQuery Node	Represents the node from the processed source or stylesheet document. One particular node is the document root, noted as *#document*. Every node is preceded by an arrow that represents what action was performed on it (entering or leaving the node).
Attributes	Attributes of the node (a list of *id="value"* pairs).
Resource	Resource file where the node is located. The complete path of the resource file is provided as tooltip.

Important:
Remarks:

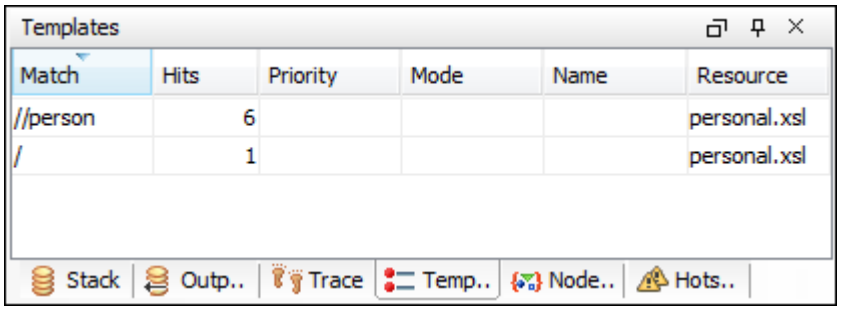
- Clicking a record highlights that node's location inside the resource.
- Only the Saxon processor shows the element attributes.
- The Xalan processor shows also the built-in rules.

Templates View

The **xsl:template** is the basic element for stylesheets transformation. The **Templates** view is only available during XSLT debugging sessions and shows all *xsl:template* instructions used by the transformation. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Being able to see the number of *hits* for each of the templates allows you to get an idea of the stylesheet coverage by template rules with respect to the input source.

Figure 576. Templates view



The contextual menu contains one action: **Go to**, which moves the selection in the editor panel to the line that contains the XSLT template displayed on the selected line from the view.

Table 51. Templates columns

Column	Description
Match	The *match* attribute of the *xsl:template*.
Hits	The number of hits for the *xsl:template*. Shows how many times the XSLT processor used this particular template.
Priority	The template priority as established by XSLT processor.
Mode	The *mode* attribute of the *xsl:template*.
Name	The *name* attribute of the *xsl:template*.
Resource	The resource file where the template is located. The complete path of the resource file is available as tooltip.

Important:
Remarks:

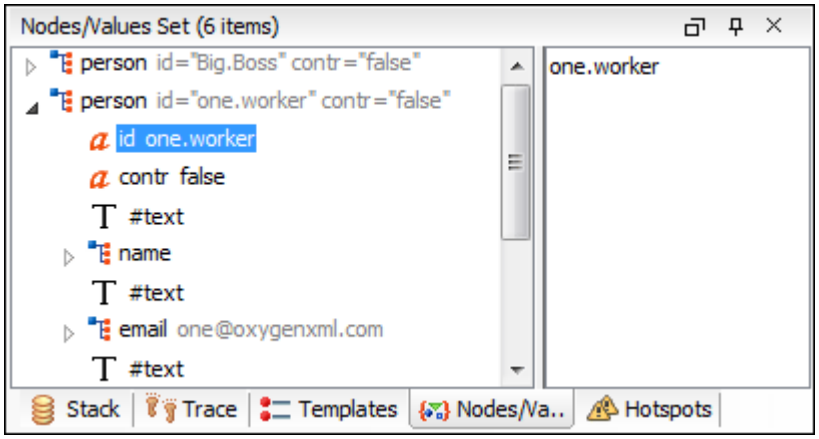
- Clicking a record highlights that template definition inside the resource.
- Saxon only shows the applied templates having at least one hit from the processor. Xalan shows all defined templates, with or without hits.
- Template table values can be sorted by clicking the corresponding column header. When clicking a column header the sorting order switches between: ascending, descending, no sort.
- Xalan shows also the built-in rules.

Nodes/Values Set View

The **Nodes/Values Set** view is always used in relation with the **Variables** view *(on page 2234)* and **XWatch** view *(on page 2226)*. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu. It shows an XSLT node set value in a tree form. This view is updated as a response to the following events:

- You click a variable that has a node set value in the **Variables** *(on page 2234)* or **XWatch** view *(on page 2226)*.
- You click a tree fragment in the **Variables** *(on page 2234)* or **XWatch** view *(on page 2226)*.
- You click an XPath expression evaluated to a node set in the **Variables** *(on page 2234)* or **XWatch** view *(on page 2226)*.

Figure 577. Node Set view



The nodes / values set is presented in a tree-like fashion. The total number of items is presented in the title bar. Nodes from a defined namespace bound to a prefix are displayed using the qualified name. If the namespace is not bound to a prefix, the namespace URI is presented before the node name. The value of the selected attribute or node is displayed in the right side panel.

Important:
Remarks:

- For longer values in the right side panel, the interface displays it with an ellipsis (...) at the end. A more detailed value is available as a tooltip when hovering over it.
- Clicking a record highlights the location of that node in the source or stylesheet view.

Variables View

The **Variables** view displays variables and parameters (local and global), along with their values. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Variables and parameters play an important role during an XSLT/XQuery transformation. Oxygen XML Editor uses the following icons to differentiate variables and parameters:

- V - Global variable.
- {V} - Local variable.
- P - Global parameter.
- {P} - Local parameter.

The following value types are available:

- **Boolean**
- **String**
- **Date** - XSLT 2.0 / 3.0 only.
- **Number**

- **Set**
- **Object**
- **Fragment** - Tree fragment.
- **Any**
- **Undefined** - The value was not yet set, or it is not accessible.

> **Note:**
>
> When Saxon 6.5 is used, if the value is unavailable, then the following message is displayed in the **Value** field: "The variable value is unavailable".
>
> When Saxon 9 is used:
>
> - If the variable is not used, the **Value** field displays "The variable is declared but never used".
> - If the variable value cannot be evaluated, the **Value** field displays "The variable value is unavailable".

- **Document**
- **Element**
- **Attribute**
- **ProcessingInstruction**
- **Comment**
- **Text**
- **Namespace**
- **Evaluating** - Value under evaluation.
- **Not Known** - Unknown types.

Figure 578. Variables View

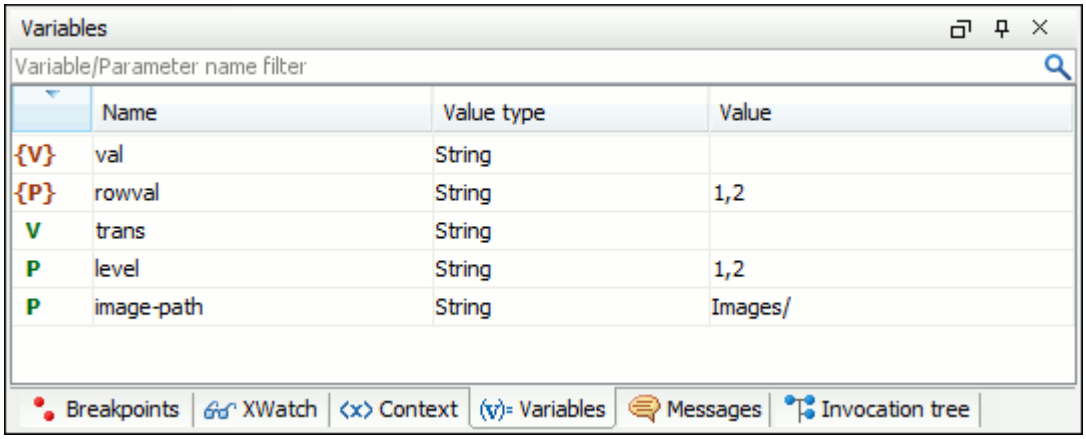


Table 52. Variables Columns

Column	Description
Name	Name of variable / parameter.

Table 52. Variables Columns (continued)

Column	Description
Value Type	Type of variable/parameter.
Value	Current value of variable / parameter.

The value of a variable (the **Value** column) can be copied to the clipboard for pasting it to other editor areas with the **Copy value** action from the contextual menu. This is useful if you have long and complex values that cannot be easily remembered just by looking at them once.

Important:
Remarks:

- Local variables and parameters are the first entries presented in the table.
- Clicking a record highlights the variable definition line.
- Variable values could differ depending on the transformation engine used or stylesheet version set.
- If the value of the variable is a node set or a tree fragment, clicking it causes the **Node Set** view *(on page 2233)* to be shown with the corresponding set of values.
- Variable table values can be sorted by clicking the corresponding column header. Clicking the column header switches between the orders: ascending, descending, no sort.

Multiple Output Documents in XSLT 2.0 and XSLT 3.0

For XSLT 2.0 and XSLT 3.0 stylesheets that store the output in multiple files by using the `xsl:result-document` instruction, the content of the file created in this way is displayed in an output view after the transformation is finished. There is one view for each `xsl:result-document` instruction so that the output is not mixed while still being presented in multiple views.

Steps in a Typical Debugging Process

Depending on your situation and needs, the debugging process might be more complex, but the following procedure is an example of a typical debugging process:

1. Open the source XML document *(on page 391)* and the XSLT/XQuery document. *(on page 391)*
2. If you are in the **Editor** *perspective (on page 3422)*, switch to the **XSLT Debugger** or **XQuery Debugger** *perspective (on page 3422)* with one of the following actions:
   - Select **Window > Open perspective > XSLT Debugger/XQuery Debugger** or the **XSLT Debugger**/**XQuery Debugger** button in the top-right corner of the interface.
   - Select **Document > XML Document > Debug scenario** or use the **Debug scenario** action on the toolbar.. This action initializes the Debugger *perspective (on page 3422)* with the

parameters of the transformation scenario. Any modification applied to the scenario parameters (the transformer engine, XSLT parameters, transformer extensions, etc.) will be saved back in the scenario when exiting from the Debugger *perspective*.

3. Select the source XML document in the XML source selector of the Control toolbar *(on page 2220)*. In the case of XQuery debugging, if your XQuery document has no implicit source, set the source selector value to **NONE**.
4. Select the XSLT/XQuery document in the XSL/XQuery selector of the Control toolbar *(on page 2220)*.
5. Set XSLT/XQuery parameters using the **Configure parameters** button on the Control toolbar *(on page 2220)*.
6. Set one or more breakpoints *(on page 2240)*.
7. Step through the stylesheet using the following buttons available on the Control toolbar *(on page 2221)*:
   - **Step into**
   - **Step over**
   - **Step out**
   - **Run**
   - **Run to cursor**
   - **Run to end**
   - **Pause**
   - **Stop**
8. Examine the data in the information views to find the bug in the transformation process.
   For more information about fixing bugs in the transformation, see: Identify the XSLT / XQuery Expression that Generated Particular Output *(on page 2237)*.

Related Information:

Identify the XSLT / XQuery Expression that Generated Particular Output *(on page 2237)*

Identify the XSLT / XQuery Expression that Generated Particular Output

To quickly spot the XSLT templates or XQuery expressions with problems, it is important to know what XSLT template in the XSLT stylesheet (or XQuery expression in the XQuery document) and what element in the source XML document generated a specified area in the output.

Some of the debugging capabilities (for example, **Step in**) can be used for this purpose. Using **Step in**, you can see how output is generated and link it with the XSLT/XQuery element being executed in the current source context. However, this can become difficult on complex XSLT stylesheets or XQuery documents that generate a large output.

You can click particular text in the **Output** view or **XHTML** output view and the editor will select the XML source context and the XSLT template/XQuery element that generated that text. Also, inspecting the whole

stack of XSLT templates/XQuery elements that determined the state of the XSLT/XQuery processor at the moment of generating the specified output area speeds up the debugging process.

This is an example of a typical procedure for identifying an expression that generated particular output:

1. Switch to the **XSLT Debugger** or **XQuery Debugger** *perspective (on page 3422)* with one of the following actions:
   - Select **Window > Open perspective > XSLT Debugger/XQuery Debugger** or the **XSLT Debugger**/**XQuery Debugger** button in the top-right corner of the interface.
   - Select **Document > XML Document > Debug scenario** or use the **Debug scenario** action on the toolbar.. This action initializes the Debugger *perspective (on page 3422)* with the parameters of the transformation scenario. Any modification applied to the scenario parameters (the transformer engine, XSLT parameters, transformer extensions, etc.) will be saved back in the scenario when exiting from the Debugger *perspective*.
2. Select the source XML document in the XML source selector of the Control toolbar *(on page 2220)*. In the case of XQuery debugging, if your XQuery document has no implicit source, set the source selector value to **NONE**.
3. Select the XSLT/XQuery document in the XSL/XQuery selector of the Control toolbar *(on page 2220)*.
4. Select the appropriate engine in the XSLT/XQuery engine selector of the Control toolbar *(on page 2221)*.
5. Set XSLT/XQuery parameters using the **Configure parameters** button on the Control toolbar *(on page 2220)*.
6. Apply the XSLT stylesheet or XQuery transformation using the **Run to end** button that is available on the Control toolbar *(on page 2222)*.
7. Inspect the mapping by clicking a section of the output in either the **Text** tab or **XHTML** tab of the Output view *(on page 357)*.

Figure 579. XHTML Output to Source Mapping

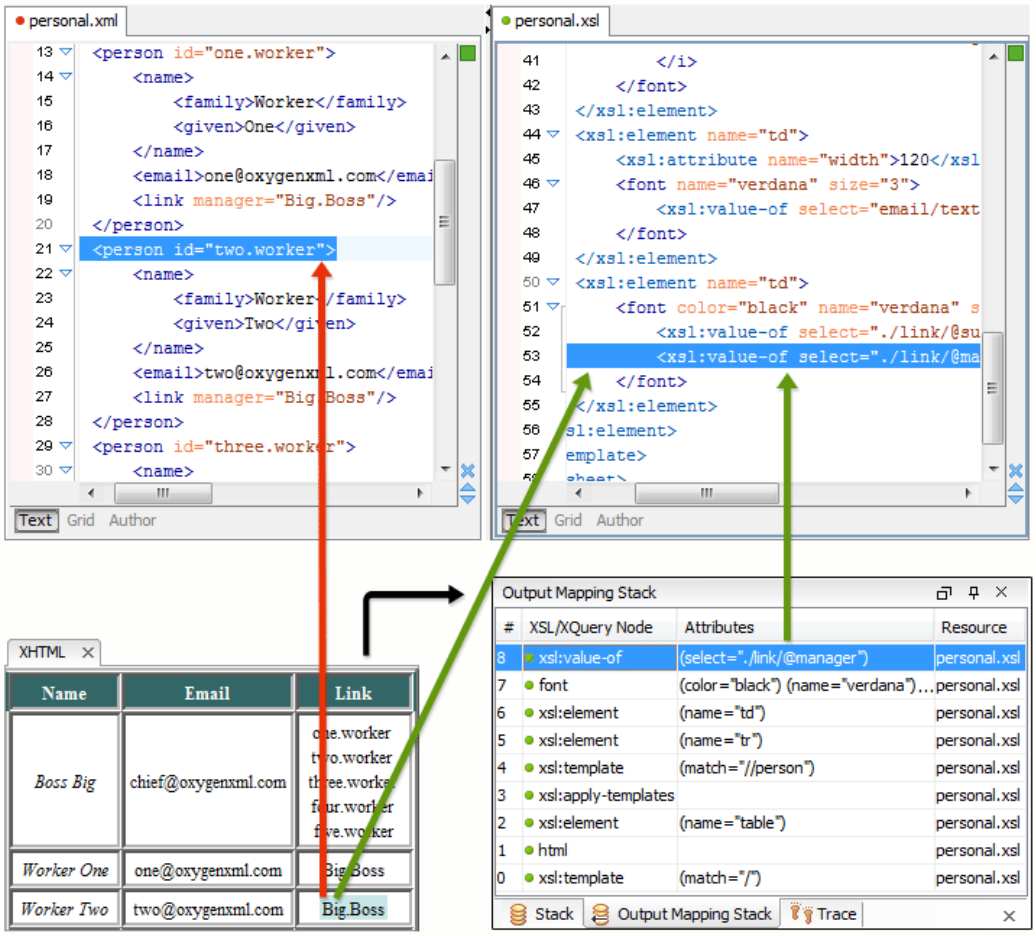

Figure 580. Text Output to Source Mapping

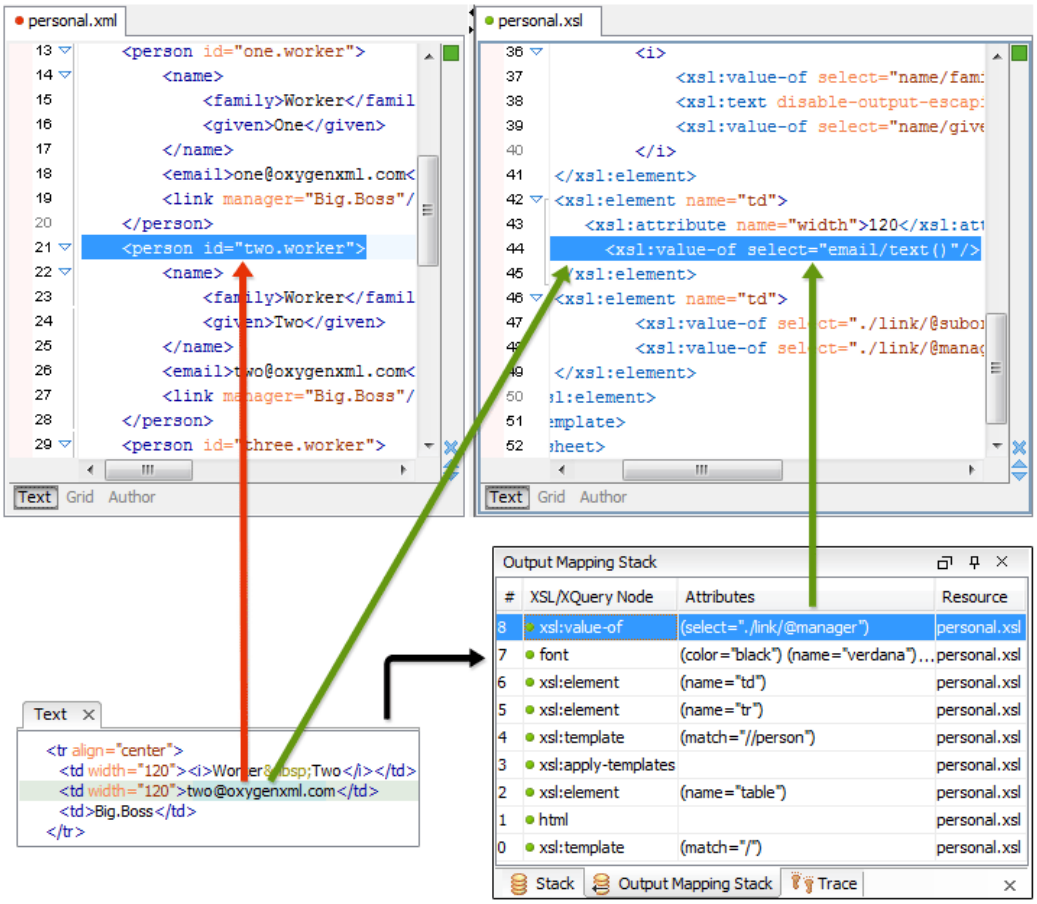


This action will highlight the XSLT / XQuery element and the XML source context. This XSLT template/ XQuery element that is highlighted in the XSLT/XQuery editor represents only the top of the stack of XSLT templates/XQuery elements that determined the state of the XSLT/XQuery processor at the moment of generating the clicked output section. In the case of complex transformations, inspecting the whole stack of XSLT templates/XQuery elements speeds up the debugging process. This stack is available in the **Output Mapping Stack** view *(on page 2229)*.

Related Information:

Output Mapping Stack View *(on page 2229)*

Trace View *(on page 2231)*

Templates View *(on page 2232)*

Using Breakpoints

The Oxygen XML Editor XSLT/XQuery Debugger allows you to interrupt XSLT/XQuery processing to gather information about variables and processor execution at particular points. To ensure *breakpoints* are persistent between work sessions, they are saved at project level. You can set a maximum of 100 *breakpoints* per project.

Inserting Breakpoints

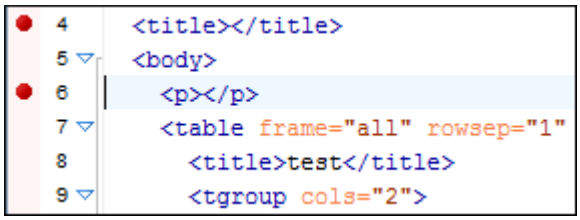
To insert a *breakpoint*, follow these steps:

1. Click the line where you want to insert the *breakpoint* in the XML source document or the XSLT/XQuery document. *Breakpoints* are automatically created on the ending line of a start tag, even if you click a different line.
2. Click the vertical stripe on the left side of the editor panel or use **Shift+F7**.

Result:

Once you insert a *breakpoint*, it is automatically added to the list in the **Breakpoints** view and you can edit its associated *condition*. A *breakpoint* can have an associated break condition that represents an XPath expression evaluated in the current debugger context. For them to be processed, their evaluation result should be a boolean value. A *breakpoint* with an associated condition only stops the execution of the Debugger if the *breakpoint condition* is evaluated as **true**.

Figure 581. Example: Breakpoints



Removing Breakpoints

To remove a *breakpoint*, click its icon ( ) in the vertical stripe on the left side of the editor panel or right-click the *breakpoint* and select **Renove** or **Remove all**.

Related Information:

Breakpoints View *(on page 2224)*

Performance Profiling of XSLT Stylesheets and XQuery Documents

Whether you are trying to identify a performance issue that is causing your production XSLT/XQuery transformation to not meet customer expectations or you are trying to proactively identify issues prior to deploying your XSLT/XQuery transformation, using the XSLT/XQuery profiler feature is essential to helping you save time and ultimately ensure a better performing, more scalable XSLT/XQuery transformation.

The XSLT/XQuery profiling feature can use any available XSLT/XQuery processor that can be used for debugging and it is available from the debugging *perspective (on page 3422)*.

Enabling the Profiler

Enabling and disabling the profiler is controlled by the **Profiler** button from the debugger Control toolbar *(on page 2220)*. The XSLT/XQuery profiler is off by default. This option is not available during a debugger session so you need to set it before starting the transformation. For information about a common debugging procedure, see Steps in a Typical Debugging Process *(on page 2236)*.

Profiling Information Views

Immediately after enabling the profiler, two new information views are added to the current debugger information views *(on page 2223)*:

- **Invocation tree** view *(on page 2243)* on left side
- **Hotspots** view *(on page 2244)* on right side

Profiling data is available only after the transformation ends successfully.

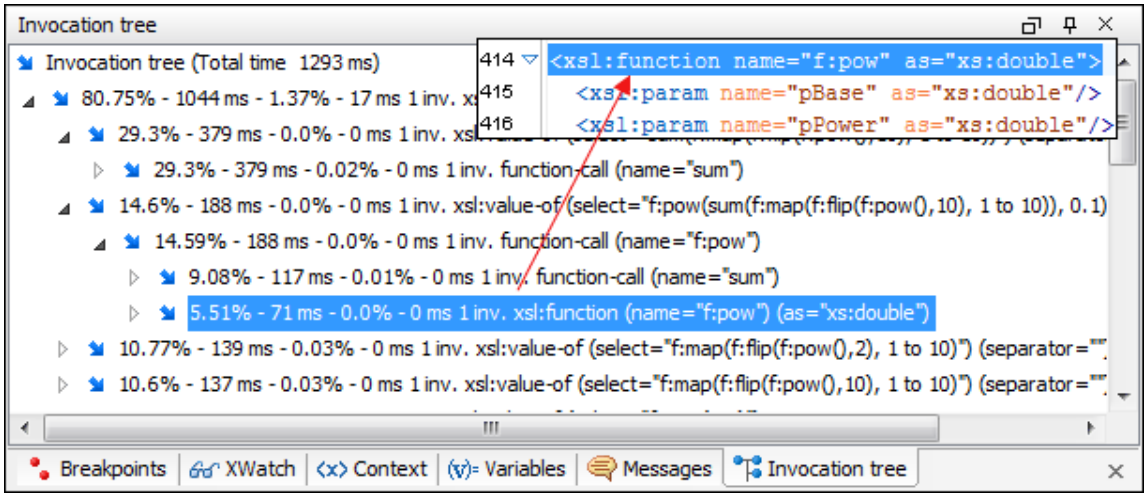
On the left side (**Invocation tree** view *(on page 2243)*), you can examine how style instructions are processed. This result view is also named call-tree, as it represents the order of style processing. The profiling result shows the duration time for each of the style-instruction including the time needed for its called children.

On the right side (**Hotspots** view *(on page 2244)*), you can immediately spot the time the processor spent in each instruction. As an instruction usually calls other instructions, the used time of the called instruction is extracted from the duration time of the caller (the hotspot only presents the inherent time of the instruction).

Source Backmapping

In either the **Invocation tree** *(on page 2243)* or **Hotspots** view *(on page 2244)*, you can use the backmapping feature to find the XSLT stylesheet or XQuery expression definition. Clicking the selected item causes Oxygen XML Editor to highlight the XSLT stylesheet or XQuery expression source line where the instruction is defined.

Figure 582. Source Backmapping



Saving and Customizing Profiling Data

The profiling data can be saved (exported) into XML and HTML format. In either the **Invocation tree** *(on page 2243)* or **Hotspots** view *(on page 2244)*, right-click anywhere in the view and select **Export to XML** or **Export to HTML**. The HTML report can be customized based upon the profiling raw data. When you select **Export to HTML**, Oxygen XML Editor will save it as XML and apply an XSLT stylesheet to render the report as XML. You can customize these stylesheets to suit your needs. By default, they are located in: `[OXYGEN_INSTALL_DIR]/frameworks/profiler/`.

Other Profiling Notes

- If you want to change the XSLT/XQuery profiler settings *(on page 266)*, use the contextual menu and choose the corresponding **View settings** entry.
- Profiling exhaustive transformations may run into an **OutOfMemory** error due to the large amount of information being collected. If this is the case, you can close unused projects when running the profiling or use high values for Java VM options `-Xms` and `-Xmx`. If this does not help you can shorten your source XML file and try again.

Resources

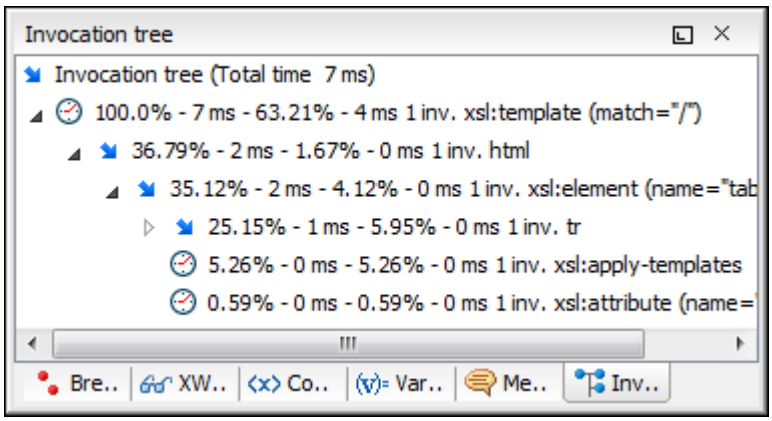
For more information about the XSLT/XQuery Profiler, watch our video demonstration:

https://www.youtube.com/embed/4ftHschjLqA

Invocation Tree View

The **Invocation Tree** view shows a top-down call tree that represents how XSLT instructions or XQuery expressions are processed. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 583. Invocation Tree View



The entries in the invocation tree include a few possible icons that indicate the following:

-  - Points to a call whose inherent time is insignificant compared to its total time.
-  - Points to a call whose inherent time is significant compared to its total time (greater than 1/3rd of its total time).

Every entry in the invocation tree includes textual information that depends on the **XSLT/XQuery profiler settings** *(on page 266)*:

- A percentage number of the total time that is calculated with respect to either the root of the tree or the calling instruction.
- A total time measurement in milliseconds or microseconds. This is the total execution time that includes calls into other instructions.
- A percentage number of the inherent time that is calculated with respect to either the root of the tree or the calling instruction.
- An inherent time measurement in milliseconds or microseconds. This is the inherent execution time of the instruction.
- An invocation count that shows how often the instruction has been invoked on this call-path.
- An instruction name that contains also the attributes description.

The **Invocation Tree** view also includes the following contextual menu actions:

Export to HTML

Selecting this option will save the profiling data as XML and then apply an XSLT stylesheet to render the report as HTML. These stylesheets are included in the subfolder: *[OXYGEN_INSTALL_DIR]*`/frameworks/profiler/`. You can use them to customize your own report based on the profiling raw data.

Export to XML

Use this option to save the profiling data as an XML file in a specified location.

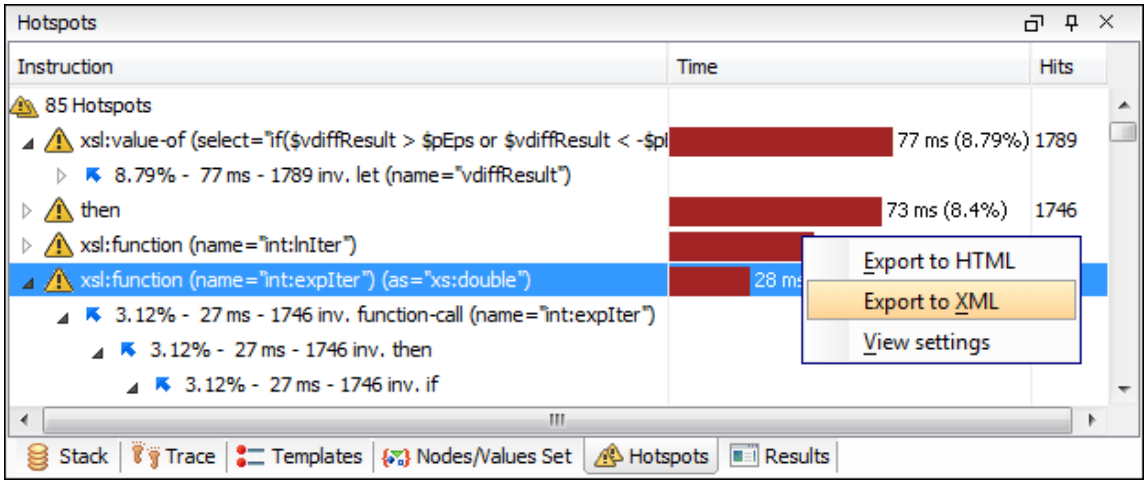
View settings

Opens the XSLT/XQuery Profiler preferences page *(on page 266)* that allows you to configure various profiling settings.

Hotspots View

The **Hotspots** view displays a list of all instruction calls that lie above the threshold defined in the **XSLT/XQuery profiler settings** *(on page 266)*. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 584. Hotspots View



By opening a hotspot instruction entry, the tree of back-traces leading to that instruction call are calculated and shown.

Every hotspot is described by the values from the following columns:

- **Instruction** - The name of the instruction.
- **Time** - The inherent time in milliseconds or microseconds of how much time has been spent in the hotspot, along with a bar whose length is proportional to this value. All calls into this instruction are summed up regardless of the particular call sequence.
- **Hits** - The invocation count of the hotspot entry.

If you click the ⚠ handle on the left side of a hotspot, a tree of back-traces will be shown.

Every entry in the backtrace tree has textual information attached to it that depends on the **XSLT/XQuery profiler settings** *(on page 266)*:

- A percentage number that is calculated with respect to either the total time or the called instruction.
- A time measured in milliseconds or microseconds of how much time has been contributed to the parent hotspot on this call-path.
- An invocation count that shows how often the hotspot has been invoked on this call-path.

> **Note:**
> This is not the number of invocations of this instruction.

- An instruction name that also contains its attributes.

The **Hotspots** view also includes the following contextual menu actions:

Export to HTML

Selecting this option will save the profiling data as XML and then apply an XSLT stylesheet to render the report as HTML. These stylesheets are included in the subfolder:

[OXYGEN_INSTALL_DIR]`/frameworks/profiler/`. You can use them to customize your own report based on the profiling raw data.

Export to XML

Use this option to save the profiling data as an XML file in a specified location.

View settings

Opens the XSLT/XQuery Profiler preferences page *(on page 266)* that allows you to configure various profiling settings.

Debugging XSLT that Call Java Extensions

It is possible to debug an XSLT that calls Java extensions. This is achieved through a transformation scenario where the Java extensions are specified, and the debugging can be done based upon the same scenario.

To debug XSLT with Java extensions, follow this procedure:

1. Create an XSLT transformation on XML scenario *(on page 1556)* for your XSLT document (select **Configure Transformation Scenario(s)** action from the toolbar, then click **New**, and select **XSLT transformation on XML**).
2. In the **New scenario** dialog box, click the **Extensions** button (in the **XSLT** tab), specify the Java extensions (JAR libraries) that are needed, and click **OK**.
3. Once you are finished configuring the transformation scenario, click **OK**, then select **Save and close**.
4. Use the **Debug scenario** action on the toolbar and the debugging will be based upon the same transformation scenario you just configured and saved.

Tip:
You could achieve this during a typical debugging process *(on page 2236)* by specifying the Java extensions using the **Edit extensions** button on the debugger control toolbar *(on page 2220)*.

Related Information:
Validating XSLT Stylesheets that Call Java Extensions *(on page 902)*

Debugging Java Extensions

The XSLT/XQuery debugger does not step into Java classes that are configured as XSLT/XQuery extensions of the transformation. To step into Java classes, inspect variable values, and set *breakpoints (on page 2240)* in Java methods, you can set up a Java debug configuration in an IDE (such as the Eclipse SDK) as described in the following steps:

1. Create a debug configuration.

    a. Make sure the `[OXYGEN_INSTALL_DIR]/lib/oxygen.jar` file and your Java extension classes are on the Java classpath.
    The Java extension classes should be the same classes that were set as an extension *(on page 2220)* of the XSLT/XQuery transformation in the debugging *perspective (on page 3422)*.

    b. Set the class *ro.sync.exml.Oxygen* as the main Java class of the configuration.
    The main Java class *ro.sync.exml.Oxygen* is located in the `oxygen.jar` file.

2. Start the debug configuration.
    Now you can set *breakpoints* and inspect Java variables as in any Java debugging process executed in the selected IDE (Eclipse SDK, and so on.).

Supported Processors for XSLT / XQuery Debugging

The following built-in XSLT processors are integrated in the debugger and can be selected in the Control Toolbar *(on page 2219)*:

- **Saxon 12.3 HE (Home Edition)** - a limited version of the Saxon 9 processor, capable of running XSLT 1.0, XSLT 2.0 / 3.0 basic and XQuery 1.0 transformations, available in both the XSLT debugger and the XQuery one,
- **Saxon 12.3 PE (Professional Edition)** - capable of running XSLT 1.0 transformations, XSLT 2.0 basic ones and XQuery 1.0 ones, available in both the XSLT debugger and the XQuery one,
- **Saxon 12.3 EE (Enterprise Edition)** - a schema-aware processor, capable of running XSLT 1.0 transformations, XSLT 2.0 /3.0 basic ones, XSLT 2.0 / 3.0 schema-aware ones and XQuery 1.0 / 3.0 ones, available in both the XSLT debugger and the XQuery debugger,
- **Saxon 6.5.5** - capable of running only XSLT 1.0 transformations, available only in the XSLT debugger,
- **Xalan 2.7.2** (Deprecated) - capable of running only XSLT 1.0 transformations, available only in the XSLT debugger.

17.

Framework and Author Mode Customization

This section contains information and tutorials about customizing the authoring experience through custom frameworks and customizing the **Author** editing mode through CSS styling or API extensions.

Creating and Configuring Custom Frameworks

Oxygen XML Editor includes built-in, configured *frameworks (on page 3420)* for DocBook, DITA, TEI, XHTML, and JATS, but you can also create your own customization to handle other types of documents. A common use-case is wanting to customize the interface to accommodate the needs of your authoring team.

Fully configuring a *framework* usually involves customizing CSS stylesheets, XML schemas, GUI components (menu actions, toolbars, inline components, content completion proposals, and more), configuring other more general settings, then bundling the framework to share with your team. The CSS and GUI components are used to customize the interface, while other general settings can be configured to accommodate custom document templates, XML catalogs, transformation scenarios, and more.

Advanced users who are familiar with API development can also create custom **Author** mode operations *(on page 2295)* for a particular framework.

This section includes information about numerous possibilities for creating and customizing a *framework*, and how to share your customization with others.

Tip:
A sample framework customization package is available that you can dabble with and use to help you get started. It can be downloaded from: https://www.oxygenxml.com/maven/com/oxygenxml/samples/oxygen-sample-framework/24.0.0.0/oxygen-sample-framework-24.0.0.0-package.zip. The package includes a sample CSS file, XSL file, schema files, document templates, an XML catalog file, custom icons, and other resources.

Creating a Framework through the Configuration Dialog

The easiest way to create a custom *framework (on page 3420)* (document type) is by extending an existing built-in framework, such as DITA or DocBook, and then making modifications to it. You can then easily share the custom framework *(on page 2406)* with your team.

To create a custom *framework* by extending an existing one, follow these steps:

1. In a location where you have full write access, create a folder structure similar to this: `custom_frameworks/dita-extension`.
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association > Locations** *(on page 147)*. Add the path to your `custom_frameworks` folder in the **Additional frameworks directories** list and click **OK** or **Apply** to save your changes.
3. Go to the **Document Type Association** preferences page *(on page 145)* and select an existing *framework* configuration (for example, **DITA**) and use the **Extend** button to create an extension for it.

   Step Result: This opens the **Document Type** Configuration dialog box *(on page 147)* where you can define the set of rules and settings for your custom framework.
4. Give the extension an appropriate name, select **External** for the **Storage** option, click the browsing button ( ) to specify the location of the custom directory you created in step 1.
5. Continue to configure the extension using the tabs on the bottom half of the dialog box. For details about each of those tabs, see the child topics in the **Document Type** Configuration dialog box *(on page 147)* section. For even more information about customizing the extended framework, see the various topics and tutorials in the Creating and Configuring Custom Frameworks *(on page 2248)* section. Make sure that you save any resources you reference in your framework configuration (CSS files, new document templates, schemas used for validation, catalogs, etc.) in your custom framework directory you created in step 1.
6. Click **OK** to close the configuration dialog box and then **OK** or **Apply** to save your changes.

   Results: You now have a fully functional *framework* that can be shared with others *(on page 2406)*.

Related information

Sharing a Framework *(on page 2406)*

Webinar: Creating Frameworks Using an Extension Script

Creating a Framework Using an Extension Script

A custom *framework (on page 3420)* (document type) can be created using a special XML descriptor file, either from scratch or by extending an existing built-in framework (such as DITA or DocBook) and then making modifications to it. You can then easily share the custom framework *(on page 2406)* with your team.

The easiest way to create such a descriptor is to use the **New** document wizard *(on page 377)* and choose the **Extend Framework Script** or **Create Framework Script** template.

Tip:
To see a visual, detailed look at how to create frameworks with an extension script, watch our webinar: **Creating Frameworks Using an Extension Script** (some samples are also available on that events page).

Creating a Custom Framework Starting from an Existing Framework

To create a custom *framework* by extending an existing one, follow these steps:

1. In a location where you have full write access, create a folder structure similar to this: `custom_frameworks/dita-extension`.
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association > Locations** *(on page 147)*. Add the path to your `custom_frameworks` folder in the **Additional frameworks directories** list and click **OK** or **Apply** to save your changes and close the dialog box.
3. Click the **New** button on the toolbar and select the **Extend Framework Script** template. Save it inside the previously configured framework path (e.g. `custom_frameworks/dita-extension`).
4. Set the `@base` attribute on the script element to the value of the name of the extended framework (e.g. **DITA**).

   > **Note:**
   > Removing the `@base` attribute will create a framework from scratch.

5. Edit the script as described in Framework Extension Script File *(on page 2251)*.

To test your customization, open a document that matches the newly created framework and inspect how your settings apply or go to **Options > Preferences > Document Type Association** and inspect the resulting framework structure.

> **Note:**
> If you want to use the framework in an older Oxygen XML Editor version that does not have support for these scripts, you can compile the script to obtain the `*.framework` file by using the **Compile Framework Extension script** action from the contextual menu or by running the scripts/compileFrameworkScript.bat external tool.

Creating a Custom Framework Without a Base Framework

To create a custom *framework* without starting from an existing one, follow these steps

1. In a location where you have full write access, create a folder structure similar to this: `custom_frameworks/dita-extension`.
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association > Locations** *(on page 147)*. Add the path to your `custom_frameworks` folder in the **Additional frameworks directories** list and click **OK** or **Apply** to save your changes and close the dialog box.
3. Click **New** button on the toolbar and select the **Create Framework Script** template. Save it inside the previously configured framework path, `custom_frameworks/dita-extension`.
4. Edit the script as described in Framework Extension Script File *(on page 2251)*.

To test your customization, open a document that matches the newly created framework and inspect how your settings apply or go to **Options > Preferences > Document Type Association** and inspect the newly generated framework structure.

Note:
If you want to use the framework in an older Oxygen XML Editor version that does not have support for these scripts, you can compile the script to obtain the `*.framework` file by using the **Compile Framework Extension script** action from the contextual menu or by running the scripts/compileFrameworkScript.bat external tool.

Webinar: Creating Frameworks Using an Extension Script

Framework Extension Script File

The framework extension file is used to describe a new framework configuration. Optionally, you can extend an existing built-in framework configuration (such as DITA or DocBook) and then make additions and changes to it.

The easiest way to create such a file is to use the **New** document wizard *(on page 377)* and choose the **Extend Framework Script** or **Create Framework Script** template.

The following examples assume that the newly created framework extends a built-in one.

Basic Information

Once you have created a new script file, you need to:

- Specify the name of the framework using the `<name>` element. Optionally, you can also add a description using the `<description>` element.
- If you want to extend an existing framework (such as DITA or DocBook), specify the name of the extended framework using the `@base` attribute on the `<script>` element.
- The `<priority>` element might be needed to instruct Oxygen XML Editor to use this new framework instead of the one being extended or another framework that matches the same document.

Example: Extending the Built-in DITA Framework

```
<script xmlns="http://www.oxygenxml.com/ns/framework/extend"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.oxygenxml.com/ns/framework/extend
  http://www.oxygenxml.com/ns/framework/extend/frameworkExtensionScript.xsd"
  base="DITA">
  <name>My custom DITA framework</name>
  <description>A custom framework based on the built-in DITA framework</description>
```

```
  <priority>High</priority>
</script>
```

Changing the Association Rules

Oxygen XML Editor identifies the type of a document when the document matches at least one of the *association rules*.

Example: Instructing the Built-in Associations to Inherit None to Add Your Own

```
<associationRules inherit="none">
  <addRule rootElementLocalName="concept"/>
  <addRule fileName="test.xml"/>
</associationRules>
```

Setting the Initial Editing Mode

You can set the default editing mode that is loaded when a document is opened for the first time. For example, if the files are usually edited in the **Author** mode, you can set it as the initial page. For more details on the possible values, see Document Type Configuration Dialog Box - Initial Edit Mode *(on page 149)*.

Example: Setting the Initial Editing Mode to Author

```
<initialPage>Author</initialPage>
```

Changing the Classpath

The **Classpath** tab displays a list of folders and *JAR (on page 3420)* libraries that hold implementations for API extensions, implementations for custom **Author** mode operations, various resources (such as stylesheets), and *framework (on page 3420)* translation files. Oxygen XML Editor loads the resources looking in the folders in the order they appear in the list.

Example: Customizing and Extending the Classpath Inherited From the Base Framework

```
  <classpath inherit="all">
    <!-- Contribute this resource before the ones inherited from the base framework
    because Oxygen loads the resources looking in the folders in the order they
    appear in the list.
    -->
    <addEntry path="${framework}/resources_2x" position="before"/>

    <removeEntry path="${baseFramework}/refactoring/"/>
  </classpath>
```

Notice:
Relative paths in the framework extension file are automatically resolved to the location of the script file.

Note:
When removing entries with framework editor variables, take into consideration how they were added in the base framework.

- An entry present in the base framework with the path `${framework}/file` can be removed using an identical path or by using the *${baseFramework}* variable: `${baseFramework}/file`.
- An entry present in the base framework with the path `${frameworkDir}/file` can be removed using an identical path or by using the *${baseFrameworkDir}* variable: `${baseFrameworkDir}/file`.

Sharing a Plugin Class Loader

If your *framework* uses the same JAVA extensions/classes as a *plugin (on page 3422)*, it is recommended that they share the same classloader. This way, the common classes are loaded by only one *Class Loader* and they will both use the same static objects and have the ability to cast objects between one another.

```
<classpath parentClassLoaderID="com.oxygenxml.git.plugin"/>
```

Setting a Default Schema

You can specify a default schema for Oxygen XML Editor to use if an XML document does not contain a schema declaration and no default validation scenario is associated with it.

Example: Setting a Default XML Schema Relative to the Script Location

```
<defaultSchema schemaType="xmlschema" href="xsd/my-schema.xsd"/>
```

Changing XML Catalogs

For cases where you need to reference the location of a schema file from a remote web location and an internet connection may not be available, an *XML Catalog (on page 3425)* may be used to map the web location to a local file system entry.

Example: Customizing and Extending the XML Catalogs Inherited From the Base Framework

```
<xmlCatalogs inherit="all">
  <!-- Contribute this resource before the ones inherited from the base framework
    because Oxygen loads the resources looking in the folders in the order they
    appear in the list.
    -->
  <addEntry path="${framework}/catalog.xml" position="before"/>

  <removeEntry path="${baseFramework}/oldCatalog.xml"/>
</xmlCatalogs>
```

Notice:
Relative paths in the framework extension file are automatically resolved to the location of the script file.

Changing the Document Templates

You can create your own custom document templates or remove templates inherited from the base framework.

Example: Customizing and Extending the XML Catalogs Inherited From the Base Framework

```
<documentTemplates inherit="all">
  <!-- Contribute this resource before the ones inherited from the base framework
    to make them appear first in the list.
    -->
  <addEntry path="${framework}/newTemplates" position="before"/>

  <removeEntry path="${baseFramework}/oldTemplates"/>
</documentTemplates>
```

Notice:
Relative paths in the framework extension file are automatically resolved to the location of the script file.

Adding New Transformation Scenarios and Removing Existing Ones

You can create new transformation scenarios and export them in one of the following locations:

- The Transformation Scenarios View *(on page 1607)*.
- The Configure Transformation Scenario(s) Dialog Box *(on page 1600)*.
- The Transformation Tab *(on page 172)*.

Example: Importing New Transformation Scenarios

The `@href` attribute from the `<addScenarios>` element is used to point to the location of the scenarios export file. Relative paths are resolved relative to the script's location. The *${framework}* editor variable also resolves to the script's location. You can also remove any scenario inherited from the base framework or set the default scenario (the one used when another specific scenario is not specified).

```
<transformationScenarios>
  <addScenarios href="scenarioExport.scenarios"/>
  <removeScenario name="DITA HTML5"/>
  <defaultScenarios>
    <name>DITA</name>
```

```
    <name>XML</name>
  </defaultScenarios>
</transformationScenarios>
```

Adding New Validation Scenarios and Removing Existing Ones

You can create new validation scenarios and export them in one of the following locations:

- The Configure Validation Scenario Dialog Box *(on page 799)*.
- The Validation Tab *(on page 173)*.

Example: Importing New Validation Scenarios

The `@href` attribute from the `<addScenarios>` element is used to point to the location of the scenarios export file. Relative paths are resolved relative to the script's location. The *${framework}* editor variable also resolves to the script's location. You can also remove any scenario inherited from the base framework or set the default scenario (the one used when another specific scenario is not specified).

```
<validationScenarios>
  <addScenarios href="validationScenarioExport.scenarios"/>
  <removeScenario name="DITA"/>
  <defaultScenarios>
    <name>DITA Validation</name>
    <name>XML Validation</name>
  </defaultScenarios>
</validationScenarios>
```

Customizing the Author Mode Through New CSS Files

The **Author** mode layout is driven by CSS rules. To customize it, you need to create new CSS files and add them in the new framework.

Example: Using Larger Fonts in Titles

```
<author>
    <css>
      <removeCss path="${framework}/base.css"/>
      <!--
        Adding CSS after the ones in the base gives the opportunity to
        override rules from previous CSSs.
      -->
      <addCss path="${framework}/titles.css" position="after"/>
    </css>
  </author>
```

The `${framework}/titles.css` file contains a rule like this:

```
*[class~='topic/title'] {
  font-size:larger;
}
```

Example: Creating an Alternate CSS That Activates When the User Selects it in the Styles Menu

```
<author>
  <css>
    <addCss path="${framework}/pink.css" title="Pink titles" alternate="true"/>
  </css>
</author>
```

The `${framework}/pink.css` file contains a rule like this:

```
*[class~='topic/title'] {
  color:#FF1493;
}
```

Control How CSS Styles are Handled in the Author mode

The **Author** mode layout is driven by CSS rules. You can configure how CSS styles are handled in the framework by using the following attributes in the script file:

selectMultipleAlternateCSS

If set to *true*, any number of alternate CSS files can be activated and they will be applied like layers. If set to false, the alternate styles are treated like a main CSS style and only one can be selected at a time.

Example: Using the selectMultipleAlternateCSS Attribute in the Script

```
<css selectMultipleAlternateCSS="true"/>
```

mergeDocumentCSS

Controls how CSS files are handled if there are CSS styles specified in the document. If set to true, they will be merged with the CSS files from the framework. If set to false, they will be ignored.

Example: Using the mergeDocumentCSS Attribute in the Script

```
<css mergeDocument="true"/>
```

Example: Changing the styling in the author mode

We add a new CSS located in the new framework directory and we remove a CSS contributed by the base framework.

```
<author>
  <css>
```

```
      <addCss path="css/style.css" />

      <removeCss path="${baseFramework}/resources/css/base.css"/>
    </css>
  </author>
```

Notice:
Relative paths in the framework extension file are automatically resolved to the location of the script file.

Defining Author Actions for the New Framework

Create external author actions *(on page 2265)*, save them in a specific subdirectory of your particular framework directory *(on page 2268)*, and they will be loaded automatically.

Removing Author Actions from the Base Framework

Suppose that the base framework configuration defines some author actions *(on page 2265)* that are added in the main menu *(on page 164)*, contextual menu *(on page 164)*, toolbar *(on page 167)*, or content completion window *(on page 167)*. If you do not want to inherit one of these actions in the new framework and you also want to remove it from all the GUI elements, you can use the `<removeAction>` element:

```
<author>
  <authorActions>
    <removeAction id="action.to.remove"/>
  </authorActions>
</author>
```

Note:
If the new framework has an external author action *(on page 2265)* with the same ID as one of the actions specified in a `<removeAction>` element, the action will not be removed from the GUI elements (menus, toolbars, content completion window).

Replacing Author Actions from the Base Framework

Suppose that the base framework configuration defines some author actions *(on page 2265)* that are added in the main menu *(on page 164)*, contextual menu *(on page 164)*, toolbar *(on page 167)*, or content completion window *(on page 167)*. If you want to keep one of these actions in all the GUI elements, but to perform differently in the new framework, just create an external author action *(on page 2265)* with the same ID as the action to replace and save it in the specific subdirectory within your new framework directory *(on page 2268)*.

Author Toolbar Configuration

The **Author** mode-specific toolbars for the new framework can be customized by:

- Adding or removing actions from toolbars.
- Changing toolbar groups by adding or removing actions.
- Creating new toolbars and action groups.

Example: Customizing the Toolbar

```
<author>
  <toolbars>
    <toolbar>

      <!-- Remove an action inherited from the base framework. -->
      <removeAction id="bold"/>

      <!-- Insert an action into an existing group -->
      <group name="${i18n(link)}">
        <addAction id="insert.note"/>
      </group>

      <!-- Add actions, separators and new groups-->
      <separator/>
      <addAction id="insert.note"/>

      <group name="New group">
        <addAction id="insert.note"/>
        <addAction id="insert.table"/>
      </group>
    </toolbar>
  </toolbars>
</author>
```

Note:
If you create a toolbar or group configuration and a toolbar/group with the same name already exists in the base framework, you will change the one inherited instead of creating a new one. You can inspect the names of the existing toolbars/groups inherited from the base framework in the Toolbar Subtab *(on page 167)*.

Example: Creating a New Toolbar

A new toolbar is created if the `@name` attribute does not match a toolbar inherited from the base.

```
<author>
    <toolbars>
      <toolbar name="Extra Toolbar">
        <!-- Add actions, separators and new groups-->
```

```
      <separator/>
      <addAction id="insert.note"/>

      <group name="New group">
        <addAction id="insert.note"/>
        <addAction id="insert.table"/>
      </group>
    </toolbar>
  </toolbars>
</author>
```

Example: Adding an Action in the Toolbar at a Specific Location

You can insert items (actions or groups) relative to other items already present in the toolbar because they were inherited from the base framework configuration. The `@anchor` attribute specifies either the ID of an action or the name of a group already present in the toolbar and the `@position` attribute specifies whether the new item should be added before or after it.

Note:
If the `@anchor` attribute is missing, the entries will be added either first or last, according to `@position` value.

```
    <toolbar>
      <addAction id="insert.note" anchor="bold" position="before"/>

      <group name="Table menu" anchor="${i18n(link)}" position="after">
        <addAction id="insert.table"/>
      </group>
    </toolbar>
```

Author Menu and Contextual Menu Configuration

The **Author** mode-specific menus for the new framework can be customized by:

- Adding or removing actions and submenus.
- Changing existing submenus by adding or removing actions.

Example: Customizing the Contextual Menu

```
  <contextualMenu>
    <!-- Add new actions and submenu -->
    <separator/>
    <addAction id="insert.table"/>
    <submenu name="Other actions">
      <addAction id="insert.note"/>
```

```
    </submenu>

    <!-- Contribute to an existing submenu -->
    <submenu name="${i18n(section)}">
      <addAction id="paragraph"/>
    </submenu>

    <!-- Remove a submenu inherited from the base framework. -->
    <removeSubmenu name="${i18n(link)}"/>
  </contextualMenu>
```

Note:
The framework main menu is configured similarly, inside a `<menu>` container.

Tip:
You can inspect the names of the submenus inherited from the base framework in the Contextual Menu Subtab *(on page 164)* and Menu Subtab *(on page 164)*.

Example: Adding an Action in the Contextual Menu at a Specific Location

You can insert new actions and submenus relative to other actions and submenus already present in the menu because they were inherited from the base framework configuration. The `@anchor` attribute specifies the ID of an **Author** mode action or a name of a submenu already present in the menu and the `@position` attribute specifies whether the new action should be added before or after it.

Note:
If the `@anchor` attribute is missing, the entries will be added either first or last, according to `@position` value.

```
  <contextualMenu>
    <addAction id="insert.note" anchor="edit.image.map" position="before"/>

    <submenu name="Table menu" anchor="${i18n(insert)}" position="after">
      <addAction id="insert.table"/>
    </submenu>
  </contextualMenu>
```

Configuring the Content Completion in Author Mode

You can replace content completion entries obtained from the associated schema with **Author** mode actions *(on page 2265)*.

In the `<authorActions>` container, you can specify the **Author** mode actions to be contributed. Optionally, you can mark them as a replacement for an existing schema proposal with the `@replacedElement` attribute.

The `<schemaProposals>` element allows you to remove proposals detected from the associated schema through the `<removeProposal>` element. If some proposals were removed in the base framework configuration and you want them re-added, you can do so through the `<addProposal>` element.

Example: Customizing the Content Completion Assistant

```
<contentCompletion>
  <authorActions>
    <addAction id="insert.note" replacedElement="note" inCCWindow="true"/>
  </authorActions>

  <schemaProposals>
    <removeProposal renderName="table"/>

    <!-- The base framework removed the "list" element proposal. We want it back... -->
    <addProposal renderName="list"/>
  </schemaProposals>
</contentCompletion>
```

Using Framework Extension Points

The **Extensions** tab specifies implementations of Java interfaces used to provide advanced functionality to the document type. Libraries that contain the implementations must be present in the classpath of your framework *(on page 2252)*. The Javadoc available at https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ contains details about how each API implementation functions.

Example: Setting a Custom Extensions Bundle

```
<extensionPoints>
  <extension
    name="extensionsBundleClassName"
    value="ro.sync.ecss.extensions.dita.map.DITAMapExtensionsBundle"/>
</extensionPoints>
```

Reusing Parts of the Script Using XInclude

Elements in the script can be specified in dedicated files that can then be referenced using XInclude in the script.

Example: Using XInclude to Reference Elements in the Script

```
<script xmlns="http://www.oxygenxml.com/ns/framework/extend">
    <name>New framework</name>
```

```
    <xi:include href="classpath.xml" xmlns:xi="http://www.w3.org/2001/XInclude"/>
</script>
```

Where the referenced `classpath.xml` has this content:

```
<classpath xmlns="http://www.oxygenxml.com/ns/framework/extend">
    <addEntry path="test.jar"/>
</classpath>
```

Notice:
Relative paths in the framework extension file are automatically resolved to the location of the script file.

Customizing the Author Mode Editing Experience for a Framework

You can customize the editing experience in **Author** mode for you and any other user who shares the same framework. This includes the ability to configure actions, menus, toolbars, icons, structure insertion shortcuts, and content completion proposals specifically for a particular *framework (on page 3420)* (document type). Advanced users who are familiar with API development can also create custom **Author** mode operations *(on page 2295)* for a particular framework.

Configuring and Managing Multiple CSS Styles for a Framework

Oxygen XML Editor provides a **Styles** drop-down menu on the toolbar that allows you to select one *main (non-alternate) CSS style (on page 3421)* and multiple *alternate CSS styles (on page 3417)*. This makes it easy to change the look of the document as it appears in **Author** mode.

An example of a common use case is when content authors want to use custom styling within a document. You can select a *main* CSS stylesheet that styles the whole document and then apply *alternate* styles, as layers, to specific parts of the document.

Note:
When altering a CSS file configured as a stylesheet for the current document framework, you can quickly check its effects in the **Author** mode by using the **Reload** document action that is available on the toolbar.

Managing the CSS Styles

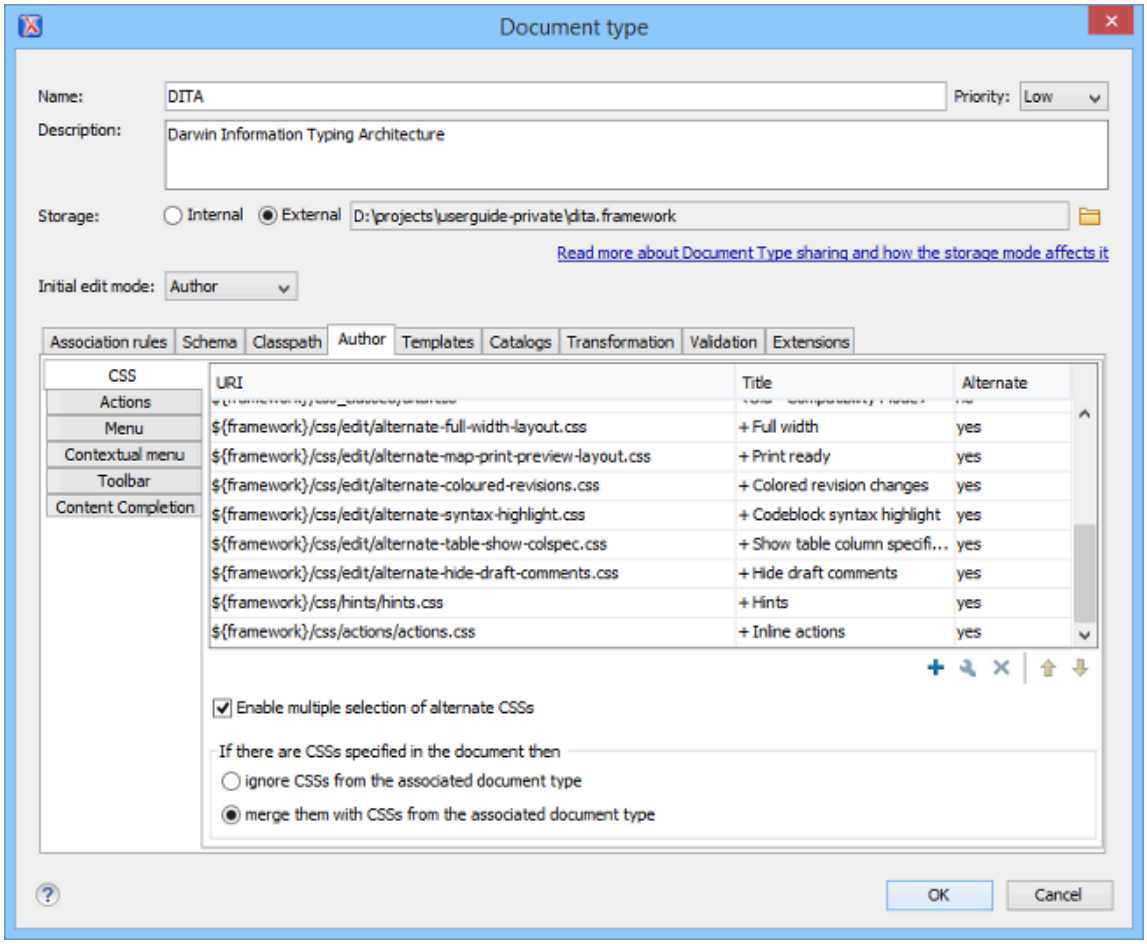
The *main (on page 3421)* and *alternate (on page 3417)* styles that are listed in the **Styles** drop-down menu can be controlled in the **Document Type** configuration dialog box *(on page 147)*. To access it, follow these steps:

1. Open the **Preferences** dialog box *(on page 131)* .
2. Go to **Document Type Association**.
3. Select the appropriate document type and click the **Edit** button.

Important:
If you do not have access rights to the folder where the *framework (on page 3420)* files are stored, you can either elevate read/write permissions on that *framework* folder or you can extend the *framework* and customize the CSS stylesheets in the extension. If you want to share the customized extension with the rest of your team, see Sharing the Extended Framework *(on page 2406)*.

The CSS styles (CSS files) associated with the particular document type are listed in the **CSS** subtab *(on page 153)* of the **Author** tab.

Figure 585. Main and Alternate CSS Styles in the Document Type Configuration Dialog Box



You can **Add**, **Edit**, or **Delete** styles from this dialog box to manage the *main (on page 3421)* and *alternate (on page 3417)* styles associated to the particular document type. You can also change the order of the styles by using the **Move Up** and **Move Down** buttons. This also changes the order that they appear in the **Styles** drop-down menu. The *alternate* styles are combined with the *main* CSS sequentially, in the order that they appear in this list. Therefore, if the same style rules are included in multiple CSS files, the *alternate* style that is listed last in this list takes precedence, since it is the last one to be combined (applied as a layer).

The **URI** column shows the path of each CSS file. The names listed in the **Styles** drop-down menu match the values in the **Title** column. The value in the **Alternate** column determines whether it is a *main* or *alternate* CSS.

If the value is *no*, it is a *main* CSS. If the value is *yes*, it is an *alternate* CSS and the style can be combined with a *main* CSS or other *alternate* styles when using the **Styles** drop-down menu.

Note:
To group alternate styles into categories (submenus), use a vertical bar character (|) in the **Title** column. You can use multiple vertical bars for multiple submenus. The text before each vertical bar will be rendered as the name of a submenu entry in the **Styles** drop-down menu, while the text after the final vertical bar is rendered as the name of the style inside the submenu.

Example: Suppose that you want to add two alternate stylesheets in separate submenus, with the *Title* column set to **My Styles|User Assistance|Hints** and **My Styles|User Actions|Inline Actions**, respectively.

URI	Title	Alternate
${framework}/css/hints/hints.css	My Styles|User Assistance| Hints	yes
${framework}/css/actions/actions.css	My Styles|User Actions|Inline actions	yes

Oxygen XML Editor will add a **My Styles** submenu with two submenus (**User Assistance** that contains the **Hints** style, and **User Actions** that contains the **Inline Actions** style) in the **Styles** drop-down menu.

The **Enable multiple selection of alternate CSSs** checkbox *(on page 154)* at the bottom of the pane must be selected for the *alternate CSS styles (on page 3417)* to be combined. They are applied like layers and you can activate any number of them. If this option is not selected, the *alternate* styles are treated like *main CSS styles (on page 3421)* and you can only select one at a time. By default, this option is selected. There are also a few options that allow you to specify how to handle the CSS if there are CSS styles specified in the document. You can choose to *ignore* or *merge* them.

The following rules apply for merging CSS styles:

- CSS files with the same title will be merged.
- CSS files without a title will contribute to all others.
- They are merged sequentially, in the order that they appear in the list.

Creating and Customizing Author Mode Actions for a Framework

There are several possibilities for creating new **Author** mode actions:

- You can create new actions for a framework or edit existing ones using the **Actions** subtab of the **Document Type** configuration dialog box *(on page 147)*. In this case, the actions are stored internally in the **.framework* file.
- You can export existing actions from the **Document Type** configuration dialog box *(on page 147)* into individual XML files or use a built-in template to create a new XML file that defines a single action. In this case, the actions are stored externally as separate XML files. The benefits of using this approach are explained in the Creating or Editing Actions Using an Individual XML File for Each Action *(on page 2265)* section below.

Creating or Editing Actions Using the Document Type Configuration Dialog Box

To add or configure **Author** mode actions for a *framework (on page 3420)* (document type) using the **Document Type** configuration dialog box *(on page 147)*, follow this procedure:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Types Association**, and select the *framework*.
2. Select your framework and click the **Edit** button (or you can use the **Duplicate** or **Extend** button to create an extension of the framework *(on page 2248)*).
3. In the resulting **Document Type** configuration dialog box *(on page 147)*, go to the **Author** tab, then the **Actions** subtab.
4. To create a new action, click the **New** button. To edit an existing action, select the action and click the **Edit** button.

   Step Result: In either case, this opens the **Action** configuration dialog box *(on page 155)* where you can configure numerous aspects of the action.
5. Once you are finished, click **OK** several times to exit the configuration dialog box.

Result: Your changes are stored in the **.framework* file for your particular framework.

Creating or Editing Actions Using an Individual XML File for Each Action

It is possible to work with **Author** mode actions outside the **Document Type** configuration dialog box *(on page 147)* and store them externally from the **.framework* file. You can either export existing actions or use a template to create a new action from scratch. The benefits of using this approach are:

- You can share, copy, or reuse each individual action across multiple projects or frameworks.
- It is easier to develop and test action configurations. After configuring the XML file that defines an action, you can test its functionality by opening a document from your particular framework and invoking the action to see if it works as expected. If you did not get the desired result, you can simply repeat the process until you are happy with the result without having to navigate through the framework configuration dialog box.

Exporting Actions

To export existing **Author** mode actions into individual XML files, follow this procedure:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Types Association**, and select the *framework*.
2. Select your framework and click the **Edit** button (or you can use the **Duplicate** or **Extend** button to create an extension of the framework *(on page 2248)*).
3. In the resulting **Document Type** configuration dialog box *(on page 147)*, go to the **Author** tab, then the **Actions** subtab.
4. **[Important]** Make sure the **Storage** option *(on page 148)* in the top part of the dialog box is set to **External** and the external location must be a subdirectory of your current framework directory (see the Notes About the Storage Path section *(on page 2268)*).
5. Select the action (or multiple actions) you want to export, right-click, and use the **Export** action (this action is also located at the bottom of the table of actions).

   Step Result: If you choose to export a single action, a resulting dialog box will allow you to select the destination path for the new XML file that contains the configuration details of the action. If you export multiple actions, they will automatically be saved as individual XML files inside a newly created folder (it will have ***_externalAuthorActions*** at the end of the folder name) inside your current framework directory.
6. **[Important]** Click **OK** several times to confirm your changes and exit the **Preferences** dialog box. The files will not be created until you exit this dialog box.

   Step Result: Each exported action is extracted from the framework configuration file and exported as an individual XML file.
7. To configure and test a particular action, you can open its corresponding XML file in Oxygen XML Editor, make changes, save the file, then open a document from your framework, test the action and repeat until you get the desired result.

   > **Note:**
   > You can add or edit the action files outside of Oxygen XML Editor, but you will need to restart the application each time to reload the changes.

Creating New Actions

To create a new **Author** mode action outside the framework configuration dialog box, follow these steps:

1. Open the **New** document wizard *(on page 377)*, search for a template called **Author Action**, and choose a storage path and file name. Remember that ultimately, it must be saved in a subdirectory of your particular framework directory (see the Notes About the Storage Path section *(on page 2268)*). Complete the creation process.

Step Result: The resulting XML file contains some hints and it is an example of an action configuration that will insert a new paragraph.

2. Configure the action as needed and save your changes.

Note:
You can use XInclude to reuse different fragments (such as XPath expressions or configured operations between actions).

Example: Reusing and XPath Expression

```
<a:operations>
    <a:operation id="InsertFragmentOperation">
      <a:xpathCondition>
        <xi:include href="expression.txt"
            xmlns:xi="http://www.w3.org/2001/XInclude" parse="text"/>
      </a:xpathCondition>
      <a:arguments>
        <a:argument name="insertLocation">
            <xi:include href="expression.txt"
                xmlns:xi="http://www.w3.org/2001/XInclude" parse="text"/>
            </a:argument>
      </a:arguments>
    </a:operation>
  </a:operations>
```

Where the content of the `expression.txt` file is `self::para`.

Example: Reusing an Entire Operation

```
  <a:operations xmlns:a="http://www.oxygenxml.com/ns/author/external-action">
      <xi:include href="operation.xml"
          xpointer="element(/1/1)" xmlns:xi="http://www.w3.org/2001/XInclude" />
  </a:operations>
```

Where the content of `operation.xml` is:

```
<a:operations xmlns:a="http://www.oxygenxml.com/ns/author/external-action">
    <a:operation id="ToggleSurroundWithElementOperation">
        <a:xpathCondition>ancestor-or-self::p</a:xpathCondition>
        <a:arguments>
            <a:argument name="element"><i/></a:argument>
        </a:arguments>
    </a:operation>
</a:operations>
```

Step Result: At this point, the action has been created but it needs to be added to the UI (in a toolbar or menu).

3. Add the new action to a UI component. For example, to add it in a toolbar, open the **Document Type** configuration dialog box *(on page 147)*, go to the **Author** tab, then the **Toolbar** subtab *(on page 167)*, and add the action.
4. To test the action, you can open a document from your framework and test the action. If you don't get the desired result, open the action file, make changes, then test them again. Repeat until you get the desired result.

> **Note:**
> You can add or edit the action files outside of Oxygen XML Editor, but you will need to restart the application each time to reload the changes.

Notes About the Storage Path

As mentioned above, it is imperative that the action configuration files be stored in a specific subdirectory of your particular framework directory.

There are two possible naming conventions for this subdirectory:

- ***{framework_directory}*/externalAuthorActions** - If there are multiple framework subdirectories inside *{framework_directory}*, using this path structure will make the actions available to all of them.
- ***{framework_directory}*/*{framework_file_name}*_externalAuthorActions** - Using this path structure will make the actions only available in the framework stored inside the `{framework_file_name}.framework` file.

> **Note:**
> When exporting actions from the UI *(on page 2266)*, this is the directory structure that is used.

Action Configuration Tips

- If an action is configured to insert a fragment that contains entities, you need to wrap it in `CDATA` markup.
- For a list of default operation, see Built-in Author Mode Operations *(on page 2269)*.

Resources

For more information about customizing **Author** mode actions, see the following resources:

- Webinar: **Improving the Authoring Experience Through Custom Actions**.
- Webinar: **Working with DITA in Oxygen - Customizing the Editing Experience**.

Framework Configuration Dialog Box: Actions Subtab *(on page 154)*

Built-in Author Mode Operations

This topic lists the default operations for the **Author** mode.

ChangeAttributeOperation

This operation allows you to add/modify/remove an attribute. You can use this operation in your own custom **Author** mode action to modify the value for a certain attribute on a specific XML element. The arguments of the operation are:

name

The attribute local name.

namespace

The attribute namespace.

elementLocation

The XPath location that identifies the element.

value

The new value for the attribute. If empty or null the attribute will be removed.

editAttribute

If an in-place editor exists for this attribute, it will automatically activate the in-place editor and start editing.

removeIfEmpty

The possible values are `true` and `false`. True means that the attribute should be removed if an empty value is provided. The default behavior is to remove it.

ChangeAttributesOperation

This operation allows you to add/modify/remove multiple attributes. You can use this operation in your own custom **Author** mode action to modify the value for one or more attributes for one or more XML elements. The arguments of the operation are:

elementLocations

The XPath location that identifies the elements whose attributes will be affected. If not defined, the element at the cursor location will be used.

attributeNames

The names of the attributes to add, modify, or remove, separated by the new-line character (`\n`). The values can be local names or Clark notations.

values

The new attributes values, each on a new line, separated by the new-line character (`\n`). An empty value will remove the attribute if `removeIfEmpty` is set to `true`.

removeIfEmpty

The possible values are `true` (default) and `false`. **True** means that the attribute will be removed if an empty value is provided.

ChangePseudoClassesOperation

Operation that sets a list of pseudo-class values to nodes identified by an XPath expression. It can also remove a list of values from nodes identified by an XPath expression. The operation accepts the following parameters:

setLocations

An XPath expression indicating a list of nodes that will have the specified list of pseudo-classes set. If it is not defined, then the element at the cursor position will be used.

setPseudoClassNames

A space-separated list of pseudo-class names that will be set on the matched nodes.

removeLocations

An XPath expression indicating a list of nodes that will have the specified list of pseudo-classes removed. If it is not defined, then the element at the cursor position will be used.

removePseudoClassNames

A space-separated list of pseudo-class names that will be removed from the matched nodes.

includeAllNodes

The possible values are `yes` and `no`. If set to `yes`, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to `no`, they are ignored.

DeleteElementOperation

Deletes the node indicated by the `elementLocation` parameter XPath expression. If missing, the operation will delete the node at the cursor location.

DeleteElementsOperation

Deletes the nodes indicated by the `elementLocations` parameter XPath expression. If missing, the operation will delete the node at the cursor location.

ExecuteCommandLineOperation

This operation allows you to start a process executing a given command line. It has the following arguments:

name

The name of the operation (or name of the console panel that corresponds to the process run by an action built over this operation).

workingDirectory

The path to the directory where the command line is executed. The default value is `"."` (current directory).

cmdLine

The command line to be executed (accepts editor variables *(on page 2286)*).

showConsole

If set to `true`, the console panel will be displayed in Oxygen XML Editor. The default value is `false`.

wait

If set to `true`, the command line will wait for the operation to finish. The default value is `false`.

ExecuteCustomizableTransformationScenarioOperation

Allows you to run a publishing transformation scenario configured at framework level with a specified set of parameters.

Notice:
This operation is not applicable to the Oxygen XML Author Component or the Oxygen XML Web Author.

It supports the following arguments:

scenarioName

The name of the transformation scenario to execute.

scenarioParameters

Provided parameters for the transformation scenario. The parameters are inserted as `name=value` pairs separated by line breaks. The set parameters are taken into account for **XSLT**, **DITA**, **Chemistry**, and **ANT** transformation scenario types.

markInProgressXPathLocation

XPath expression that identifies the element(s) on which a specific `-oxy-transformation-in-progress` pseudo class is set before transformation is started. The pseudo class is reset when the transformation ends or is cancelled. If this XPath expression is not defined, the current node is used.

markOthersInProgressXPathLocation

XPath expression that identifies other elements on which a specific `-oxy-transformation-in-progress-others` pseudo class is set before the transformation is started. The pseudo class is reset when the transformation ends.

ExecuteMultipleActionsOperation

This operation allows the execution of a sequence of actions, defined as a list of action IDs. The actions must be defined by the corresponding *framework*, or one of the common actions for all *frameworks* supplied by Oxygen XML Editor.

actionIDs

The action IDs list that will be executed in sequence, the list must be a string sequence containing the IDs separated by commas or new lines.

ExecuteMultipleWebappCompatibleActionsOperation

An implementation of an operation that runs a sequence of Oxygen XML Web Author-compatible actions, defined as a list of IDs.

ExecuteTransformationScenariosOperation

This operation allows running one or more transformation scenarios defined in the current *document type association (on page 3419)*, in the project options, or in the global options. A use case would be to add a toolbar button that triggers publishing to various output formats. The argument of the operation is:

scenarioNames

The list of scenario names that will be executed, separated by new lines.

ExecuteValidationScenariosOperation

This operation allows running one or more validation scenarios defined in the current *document type association (on page 3419)*, in the project options, or in the global options. The single argument for the operation is:

scenarioNames

The list of scenario names that will be executed, separated by new lines.

InsertEquationOperation

Inserts a fragment containing a MathML equation at the cursor offset. The argument of this operation is:

fragment

The XML fragment containing the MathML content that should be inserted.

InsertFragmentOperation

Inserts an XML fragment at the current cursor position. The selection, if there is one, remains unchanged. The fragment will be inserted in the current context of the cursor position meaning that if the current XML document uses some namespace declarations then the inserted fragment must use the same declarations. The namespace declarations of the inserted fragment will be adapted to the existing namespace declarations of the XML document. For more details about its list of parameters, see Arguments of InsertFragmentOperation *(on page 2292)*.

InsertOrReplaceFragmentOperation

Similar to **InsertFragmentOperation** *(on page 2273)*, except it removes the selected content before inserting the fragment. Also, the **insertPosition** parameter has another possible value: **Replace**. If this value is used, the operation deletes the node selected by the XPath expression denoted by the **insertLocation** parameter. For more details about its list of parameters, see Arguments of InsertFragmentOperation *(on page 2292)*.

InsertOrReplaceTextOperation

Inserts a text at current position removing the selected content, if any. The argument of this operation is:

text

The text section to insert.

InsertXIncludeOperation

Insert an `XInclude` element at the cursor offset. Opens a dialog box that allows you to browse and select content to be included in your document and automatically generates the corresponding XInclude instruction.

JSOperation

Allows you to call the Java API from custom JavaScript content. For some sample **JSOperation** implementations, see https://github.com/oxygenxml/javascript-sample-operations.

Notice:
For the Oxygen XML Web Author, this operation cannot be invoked using the JavaScript API. However, it can be used when configuring an Action for Author mode using the Document Type Configuration dialog box *(on page 158)*.

This operation accepts the following parameter:

script

The JavaScript content to execute. It must have a function called `doOperation()`, which can use the predefined `authorAccess` variable. The `authorAccess` variable has access to the entire *ro.sync.ecss.extensions.api.AuthorAccess* Java API.

The following example is a script that retrieves the current value of the **type** attribute on the current element, allows the end-user to edit its new value and sets the new value in the document:

```
function doOperation(){
 //The current node is either entirely selected...
 currentNode = authorAccess.getEditorAccess().getFullySelectedNode();
 if(currentNode == null){
 //or the cursor is placed in it
 caretOffset = authorAccess.getEditorAccess().getCaretOffset();
 currentNode = authorAccess.getDocumentController().getNodeAtOffset
                          (caretOffset);
 }
 //Get current value of the @type attribute
  currentTypeValue = "";
  currentTypeValueAttr = currentNode.getAttribute("type");
  if(currentTypeValueAttr != null){
    currentTypeValue = currentTypeValueAttr.getValue();
  }
 //Ask user for new value for attribute.
 newTypeValue = javax.swing.JOptionPane.showInputDialog
                         ("Input @type value", currentTypeValue);
 if(newTypeValue != null){
   //Create and set the new attribute value for the @type attribute.
   attrValue = new Packages.ro.sync.ecss.extensions.api.node.AttrValue
                         (newTypeValue);
   authorAccess.getDocumentController().setAttribute
                         ("type", attrValue, currentNode);
 }
}
```

Tip:
You can call functions defined inside a script called `commons.js` from your custom script content so that you can use that external script file as a library of functions. Note that this `commons.js` file must be placed in the root of the *framework* directory (for example, *`[OXYGEN_INSTALL_DIR]`*`/frameworks/dita/commons.js`) because that is the only location where Oxygen XML Editor will look for it.

MoveCaretOperation

Flexible operation for moving the cursor within a document and it is also capable of performing a selection. The operation accepts the following arguments:

xpathLocation

An XPath expression that identifies the node relative to where the cursor will be moved. If the expression identifies more than one node, only the first one will be taken into account.

position

The position relative to the node obtained from the XPath expression where the cursor will be moved. When also choosing to perform a selection, you can use the following possible values:

- **Before** - Places the cursor at the beginning of the selection.
- **Inside, at the beginning** - Places the cursor at the beginning of the selection.
- **After** - Places the cursor at the end of the selection.
- **Inside, at the end** - Places the cursor at the end of the selection.

selection

Specifies if the operation should select the element obtained from the XPath expression, its content, or nothing at all. The possible values of the argument are: `None`, `Element`, and `Content`.

MoveElementOperation

Flexible operation for moving an XML element to another location from the same document. XPath expressions are used to identify the source element and the target location. The operation takes the following parameters:

sourceLocation

XPath expression that identifies the content to be moved.

deleteLocation

XPath expression that identifies the node to be removed. This parameter is optional. If missing, the **sourceLocation** parameter will also identify the node to be deleted.

surroundFragment

A string representation of an XML fragment. The moved node will be wrapped in this string before moving it in the destination.

targetLocation

XPath expression that identifies the location where the node must be moved to.

insertPosition

Argument that indicates the insert position.

moveOnlySourceContentNodes

When set to `true`, only the content of the source element is moved.

processTrackedChangesForXpathLocations

When nodes are located via an XPath expression and the nodes are deleted with *Change Tracking (on page 3424)* enabled, they are considered as being present by default (thus, the *change tracking* is ignored). If you set this argument to `true` and *change tracking* is enabled,

deleted nodes will be ignored when the XPath locations are computed (thus, the *change tracking* is NOT ignored).

alwaysPreserveTrackedChangesInMovedContent

When set to `true`, tracked changes are included when a copied fragment is inserted in a document, regardless of the current state of the **Track Changes** feature.

OpenInSystemAppOperation

Opens a resource in the system application that is associated with the resource in the operating system. The arguments of this operation are:

resourcePath

An XPath expression that, when executed, returns the path of the resource to be opened. Editor variables *(on page 332)* are expanded in the value of this parameter, before the expression is executed.

isUnparsedEntity

Possible values are `true` or `false`. If the value is `true`, the value of the **resourcePath** argument is treated as the name of an unparsed entity.

ReloadContentOperation

Reloads the content of the editor by re-reading the information from the URL used to open it. It accepts the following argument:

markAsNotModified

The possible values are `true` and `false`. After reloading the editor, the content may appear as modified and in some cases where the content is already present on the file server, you would not want the user to save it again. You can set this flag to `true` to prevent the editor from showing the content as modified.

RemovePseudoClassOperation

An operation that removes a pseudo-class from an element. Accepts the following parameters:

name

Name of the pseudo-class to be removed.

includeAllNodes

The possible values are `yes` and `no`. If set to `yes`, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to `no`, they are ignored.

elementLocation

The XPath location that identifies the element. If it is not defined, then the element at the cursor position is used. It can also identify multiple elements, in which case the pseudo class will be removed from all of them.

Example:

Suppose that there is a pseudo-class called `myClass` on the element `paragraph` and there are CSS styles matching the pseudo-class.

```
paragraph:myClass{
  font-size:2em;
  color:red;
}
paragraph{
  color:blue;
}
```

In the previous example, by removing the pseudo-class, the layout of the `paragraph` is rebuilt by matching the other rules (in this case, the foreground color of the `paragraph` element will become blue.

RenameElementOperation

This operation allows you to rename all occurrences of the elements identified by an XPath expression. The operation requires two parameters:

elementName

The new element name.

elementLocation

The XPath expression that identifies the element occurrences to be renamed. If this parameter is missing, the operation renames the element at current cursor position.

ReplaceElementContentOperation

An operation that replaces the content of the element at the cursor location (or fully selected element). The operation accepts the following parameters:

fragment

Specifies the fragment that will be inserted as the element content.

elementLocation

An XPath expression that identifies the element. If it is not defined, then the element at the cursor position is used.

SetPseudoClassOperation

An operation that sets a pseudo-class to an element. The operation accepts the following parameters:

elementLocation

An XPath expression that identifies the element that will have the pseudo-class set. If it is not defined, then the element at the cursor position is used.

name

The pseudo-class local name.

includeAllNodes

The possible values are `yes` and `no`. If set to `yes`, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to `no`, they are ignored.

ShowElementDocumentationOperation

Opens the associated specification HTML page for the current element. The operation accepts as parameter a URL pattern that points to the HTML page containing the documentation.

StopCurrentTransformationScenarioOperation

Allows you to stop the transformation scenario that is currently running.

Notice:
This operation is not applicable to the Oxygen XML Author Component or the Oxygen XML Web Author.

SurroundWithFragmentOperation

Surrounds the selected content with a text fragment. Since the fragment can have multiple nodes, the surrounded content will be always placed in the first leaf element. If there is no selection, the operation will simply insert the fragment at the cursor position. For more details about the list of parameters go to: Arguments of SurroundWithFragmentOperation *(on page 2294)*.

SurroundWithTextOperation

This operation has two arguments (two text values) that will be inserted before and after the selected content. If there is no selected content, the two sections will be inserted at the cursor position. The arguments of the operation are:

header

The text that is placed before the selection.

footer

The text that is placed after the selection.

TogglePseudoClassOperation

An implementation of an operation to toggle on/off the pseudo-class of an element. Accepts the following parameters:

name

Name of the pseudo-class to be toggled on/off.

includeAllNodes

The possible values are `yes` and `no`. If set to `yes`, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to `no`, they are ignored.

elementLocation

The XPath location that identifies one or more elements that will have the pseudo class toggled. If it is not defined, then the element at the cursor position is used.

Example:

```
paragraph:myClass{
  color:red;
}
paragraph{
  color:blue;
}
```

By default, the paragraph content is rendered in blue. Suppose that you have a `TogglePseudoClassOperation` configured for the `myClass` pseudo-class. Invoking it the first time will set the `myClass` pseudo-class and the paragraph will be rendered in red. Invoking the operation again, will remove the pseudo-class and the visible result will be a blue rendered `paragraph` element.

ToggleSurroundWithElementOperation

This operation allows wrapping and unwrapping content in a specific wrapper element that can have certain attributes specified on it. It is useful to implement toggle actions such as highlighting text as bold, italic, or underline. The operation supports processing multiple selection intervals, such as multiple cells within a table column selection. The arguments of the operation are:

element

The element to wrap or unwrap content.

schemaAware

This argument applies only on the surround with element operation and controls whether or not the insertion is valid, based upon the schema. If the insertion is not valid, then wrapping action will be broken up into smaller intervals until the wrapping action is valid. For example, if you try

to wrap a *paragraph* element with a *bold* element, it would not be valid, so the operation will wrap the text inside the paragraph instead, since it would be valid at that position.

ToggleCommentOperation

This operation allows for commenting or un-commenting the selected content. It does not have any arguments. If the selection is text, the operation wraps the selection in a comment. If the selection is a comment, the operation removes the comment.

UnwrapTagsOperation

This operation allows removing the element tags either from the current element or for an element identified with an XPath location. The argument of the operation is:

unwrapElementLocation

An XPath expression that identifies the element to unwrap. If it is not defined, the element at the cursor position is unwrapped.

XQueryUpdateOperation

Allows you to execute an XQuery Update script directly over content in **Author** mode.

Notice:
This operation is not applicable to the Oxygen XML Author Component or the Oxygen XML Web Author.

It supports the following arguments:

script

The XQuery Update script to be executed. The value can either be an XQuery script or a URL that points to the XQuery Update script. You can use the *${framework} (on page 339)* or *${frameworkDir} (on page 340)* editor variables to refer the scripts from the *framework* directory.

The script will be executed in the context of the node at the cursor position. If the script declares the following variable, it will also receive the selected nodes (assuming that entire nodes are selected):

```
declare variable $oxyxq:selection external;
```

In the example below *(on page 2281)*, you can see how this argument is used.

externalParams

A string that can assign multiple key-value pairs separated by a comma or a new line character.

For example, if an XQuery script declares two external parameters like this:

```
declare variable $param1 external;
declare variable $param2 external;
```

You can pass custom values for each parameter by setting the **externalParams** to `param1=value1,param2=value2`.

expandXincludeReferences

Makes all *Xinclude* elements transparent to the XQuery transformer. When the *Xinclude* references are transparent, the **XQueryUpdateOperation** can use the referenced elements for further processing in the current document, but it cannot change their values in the original document. The default value is `false`, which means the *Xinclude* elements are not transparent.

An example of an *XQuery Update Script* that converts paragraphs to list items:

```
declare namespace oxyxq = "http://www.oxygenxml.com/ns/xqu";
(: This variable will be linked to the selected nodes assuming that there are
actually fully selected nodes. For example this selection will return null:
<p>{SEL_START}text{SEL_END} in para</p>
but this will give two "p" elements:
{SEL_END}<p>text</p><p>text2</p>{SEL_END}

If a multiple selection exists it will also be processed and forwarded.
 Again, only fully selected nodes will be passed.
:)
declare variable $oxyxq:selection external;

(: We will process either the selection or the context node :)
let $toProcess := if (empty($oxyxq:selection)) then
    (.)
else
    ($oxyxq:selection)

return if (not(empty($toProcess))) then
        (
        (: Create the list :)
        let $ul :=
        <ul>
            {
                for $sel in $toProcess
                return
                    <li>{$sel}</li>
            }
        </ul>
```

```
        return
            (
            (: Delete the processed nodes :)
            for $sel in $toProcess
            return
                delete node $sel,
            (: Inserts the constructed list :)
            insert node $ul
                before $toProcess[1]
            )
        )
    else
        ()
```

XSLTOperation and XQueryOperation

Applies an XSLT or XQuery script on a source element and then replaces or inserts the result in a specified target element.

Notice:
For Oxygen XML Web Author, these operations cannot be invoked using the JavaScript API.

These operations accept the following parameters:

sourceLocation

An XPath expression indicating the element that the script will be applied on. If it is not defined, then the element at the cursor position will be used.

There may be situations where you want to look at an ancestor of the current element and make decisions in the script based on that. To do this, you can set the **sourceLocation** to point to an ancestor node then use the `oxy:current-element()` function to access the current element, as in the following example:

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="2.0"
  xpath-default-namespace="http://docbook.org/ns/docbook"
  xmlns:oxy="http://www.oxygenxml.com/ns/author/xpath-extension-functions"
                          exclude-result-prefixes="oxy">
    <xsl:template match="/">
        <xsl:apply-templates select="oxy:current-element()"/>
    </xsl:template>

    <xsl:template match="para">
        <!-- And the context is again inside the current element,
        but we can use information from the entire XML -->
```

```
        <xsl:variable
            name="keyImage" select="//imagedata[@fileref='images/lake.jpeg']
              /ancestor::inlinemediaobject/@xml:id/string()"/>
        <xref linkend="{$keyImage}" role="key_include"
                xmlns="http://docbook.org/ns/docbook"/>
    </xsl:template>
</xsl:stylesheet>
```

targetLocation

An XPath expression indicating the insert location for the result of the transformation. If it is not defined then the insert location will be at the cursor location.

script

The script content (XSLT or XQuery). The base system ID for this will be the *framework* file, so any include/import reference will be resolved relative to the `.framework` file that contains this action definition.

For example, for the following script, the imported `xslt_operation.xsl` needs to be located in the current *framework* directory.

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
            version="1.0">
    <xsl:import href="xslt_operation.xsl"/>
</xsl:stylesheet>
```

You can also use a path for an included or imported reference. When using a path, the following apply:

- A relative path is resolved to the *framework* directory.
- The *${framework}* editor variable *(on page 339)* can also be used to reference resources from the *framework* directory.
- The path is passed through the catalog mappings. It helps to use an absolute URL (for instance, `http://www.oxygenxml.com/fr/testy.xsl`) and map it in the `catalog.xml` file from the *framework* directory to a resource from the *framework*.

action

The insert action relative to the node determined by the target XPath expression. It can be: Replace, At cursor position, Before, After, Inside as first child or Inside as last child.

caretPosition

The position of the cursor after the action is executed. It can be: `Preserve`, `Before`, `Start`, `First editable position`, `End`, or `After`. If this parameter is not set, you can still indicate the position of the cursor by using the *${caret}* editor variable *(on page 338)* in the inserted content.

expandEditorVariables

Parameter controlling the expansion of editor variables *(on page 332)* returned by the script processing. Expansion is enabled by default.

suspendTrackChanges

It has 2 possible values (`true` and `false`). The default value is `false`. When set to `true`, the *Track Changes (on page 3424)* feature is deactivated. When using this argument, after the action is finished, the state of the *Track Changes* feature is restored to its initial value.

externalParams

A string that can assign multiple key-value pairs separated by a comma or a new line character.

For example, if an XQuery script declares two external parameters like this:

```
declare variable $param1 external;
declare variable $param2 external;
```

You can pass custom values for each parameter by setting the **externalParams** to `param1=value1,param2=value2`.

escapeEntityRefs

Escapes entity references in processed content to plain text and unescapes them back in the returned content.

XSLTOperation Example: Sort a list with respect to the language declared on the root element:

Suppose you want an action that will sort a list with respect to the language declared on the root element and you have an XML file like this:

```
<article xml:lang="en">
  <ul>
     <li>B</li>
     <li>C</li>
     <li>A</li>
  </ul>
</article>
```

The **XSLTOperation** needs to be configured as follows:

- **sourceLocation** is set to /* so that the script has access to the root element and its children.
- **targetLocation** is left untouched (assuming that the action is active only when the cursor is inside the list).

The XSLT script would look like this:

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:oxy="http://www.oxygenxml.com/ns/author/xpath-extension-functions"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  exclude-result-prefixes="xs oxy" version="2.0">
```

```
  <xsl:template match="/">
      <!--
          sourceLocation parameter was set to /* to have a larger context.
          We can pinpoint the element that contained the caret
          using the oxy:current-element() function.
      -->
      <xsl:apply-templates select="oxy:current-element()"/>
  </xsl:template>

  <xsl:template match="ul">

    <!-- Because the sourceLocation parameter was set to /* we now have access to
         the root element and its attributes. -->
    <xsl:variable name="lang" select="/*/@xml:lang"/>
    <xsl:variable name="collationURI">
      <xsl:value-of select="concat('http://www.w3.org/2013/collation/UCA?lang=', $lang)"/>
    </xsl:variable>

      <xsl:copy>
          <xsl:copy-of select="@*"/>

          <!-- Copy the list items, but sorted. -->
          <xsl:apply-templates select="li">
              <xsl:sort collation="{$collationURI}" select="text()"/>
          </xsl:apply-templates>
      </xsl:copy>
  </xsl:template>

  <!-- This copy template will handle the contents of the list items. -->
  <xsl:template match="@* | node()">
      <xsl:copy>
          <xsl:apply-templates select="@* | node()"/>
      </xsl:copy>
  </xsl:template>
</xsl:stylesheet>
```

Using Entities and Xincludes with the XSLTOperation

- **Entities** are treated as plain text and not expanded.
- **Xincludes** are resolved in the result, and you can alter the XML obtained afterward using the XSLT/XQuery script of the operation, but you cannot alter the included document itself.

Editor Variables in Author Mode Operations

Author mode operations can include parameters that contain the following editor variables *(on page 332)*:

- **${caret}** - The position where the cursor is located. This variable can be used in a code template, in **Author** mode operations, or in a **selection** *plugin*.

  > **Note:**
  > The **${caret}** editor variable is available only for parameters that take XML content as values. It is replaced with the **${UNIQUE_CARET_MARKER_FOR_AUTHOR}** macro. The default Author operations process this macro and position the cursor at the designated offset.

  > **Note:**
  > The **${caret}** editor variable can be used for setting a fixed cursor position inside an XML fragment. To set the cursor position depending on the fragment inserted in the document, you can use **AuthorDocumentFilter** and inside the **insertFragment(AuthorDocumentFilterBypass, int, AuthorDocumentFragment)** method, use the **AuthorDocumentFragment.setSuggestedRelativeCaretOffset(int)** API on the given fragment.

- **${selection}** - The currently selected text content in the currently edited document. This variable can be used in a code template, in **Author** mode operations, or in a **selection** *plugin*.
- **${ask('message', type, ('real_value1':'rendered_value1'; 'real_value2':'rendered_value2'; ...), 'default_value', @id)}** - To prompt for values at runtime, use the *ask('message', type, ('real_value1':'rendered_value1'; 'real_value2':'rendered_value2'; ...), 'default-value')* editor variable. You can set the following parameters:
  - **'message'** - The displayed message. Note the quotes that enclose the message.
  - **'default-value'** - Optional parameter. Provides a default value.
  - **@id** - Optional parameter. Used for identifying the variable to reuse the answer using the **${answer(@id)}** editor variable.
  - **type** - Optional parameter (defaults to **generic**), with one of the following values:

    > **Note:**
    > The title of the dialog box will be determined by the type of parameter and as follows:
    > - For *url* and *relative_url* parameters, the title will be the name of the parameter and the value of the *'message'*.
    > - For the other parameters listed below, the title will be the name of that respective parameter.
    > - If no parameter is used, the title will be "Input".

Notice:
Editor variables that are used within a parameter of another editor variable must be escaped within single quotes for them to be properly expanded. For example:

```
${ask( 'Provide a date',generic,'${date(yyyy-MM-dd'T'HH:MM)}')}
```

Parameter	
generic (default)	**Format**: *${ask('message', generic, 'default')}*
	Description: The input is considered to be generic text that requires no special handling.
	Example: ▪ *${ask('Hello world!')}* - The dialog box has a *Hello world!* message displayed. ▪ *${ask('Hello world!', generic, 'Hello again!')}* - The dialog box has a *Hello world!* message displayed and the value displayed in the input box is *'Hello again!'*.
url	**Format:** *${ask('message', url, 'default_value')}*
	Description: Input is considered a URL. Oxygen XML Editor checks that the provided URL is valid.
	Example: ▪ *${ask('Input URL', url)}* - The displayed dialog box has the name *Input URL*. The expected input type is URL. ▪ *${ask('Input URL', url, 'http://www.example.com')}* - The displayed dialog box has the name *Input URL*. The expected input type is URL. The input field displays the default value *http://www.example.com*.
relative_url	**Format:** *${ask('message', relative_url, 'default')}*
	Description: Input is considered a URL. This parameter provides a file chooser, along with a text field. Oxygen XML Editor tries to make the URL relative to that of the document you are editing. **Note:** If the *$ask* editor variable is expanded in content that is not yet saved (such as an *untitled* file, whose path cannot be determined), then Oxygen XML Editor will transform it into an absolute URL.
	Example:

Parameter	
	${ask('File location', relative_url, 'C:/example.txt')} - The dialog box has the name *'File location'*. The URL inserted in the input box is made relative to the currently edited document location.
password	**Format**: *${ask('message', password, 'default')}*
	Description: The input is hidden with bullet characters.
	Example: ▪ *${ask('Input password', password)}* - The displayed dialog box has the name *'Input password'* and the input is hidden with bullet symbols. ▪ *${ask('Input password', password, 'abcd')}* - The displayed dialog box has the name *'Input password'* and the input hidden with bullet symbols. The input field already contains the default **abcd** value.
combobox	**Format:** *${ask('message', combobox, ('real_value1':'rendered_value1';..-.;'real_valueN':'rendered_valueN'), 'default')}*
	Description: Displays a dialog box that offers a drop-down menu. The drop-down menu is populated with the given *rendered_value* values. Choosing such a value will return its associated value (*real_value*). **Note:** The list of *'real_value':'rendered_value'* pairs can be computed using *${xpath_eval()}*. **Note:** The *'default'* parameter specifies the default-selected value and can match either a key or a value.
	Example: ▪ *${ask('Operating System', combobox, ('win':'Microsoft Windows';'macos':'macOS';'lnx':'Linux/UNIX'), 'macos')}* - The dialog box has the name *'Operating System'*. The drop-down menu displays the three given operating systems. The associated value will be returned based upon your selection. **Note:** In this example, the default value is indicated by the *osx* key. However, the same result could be obtained if the de-

Parameter	
	fault value is indicated by *macOS*, as in the following example: *${ask('Operating System', combobox, ('win':'Microsoft Windows';'macos':'macOS';'lnx':'Linux/UNIX'), 'macOS')}* ▪ *${ask('Mobile OS', combobox, ('ios':'iOS';'and':'Android'), 'Android')}* ▪ *${ask('Mobile OS', combobox, (${xpath_eval(for $pair in (['ios', 'iOS'], ['and', 'Android']) return '"' || $pair?1 || '":"' || $pair?2 || '";')}), 'ios')}*
editable_combobox	**Format:** *${ask('message', editable_combobox, ('real_value1':'rendered_value1';...;'real_valueN':'rendered_valueN'), 'default')}*
	Description: Displays a dialog box that offers a drop-down menu with editable elements. The drop-down menu is populated with the given *rendered_value* values. Choosing such a value will return its associated real value (*real_value*) or the value inserted when you edit a list entry. **Note:** The list of *'real_value':'rendered_value'* pairs can be computed using *${xpath_eval()}*. **Note:** The *'default'* parameter specifies the default-selected value and can match either a key or a value.
	Example: ▪ *${ask('Operating System', editable_combobox, ('win':'Microsoft Windows';'macos':'macOS';'lnx':'Linux/UNIX'), 'macos')}* - The dialog box has the name *'Operating System'*. The drop-down menu displays the three given operating systems and also allows you to edit the entry. The associated value will be returned based upon your selection or the text you input. ▪ *${ask('Operating System', editable_combobox, (${xpath_eval(for $pair in (['win', 'Microsoft Windows'], ['macos', 'macOS'], ['lnx', 'Linux/UNIX']) return '"' || $pair?1 || '":"' || $pair?2 || '";')}), 'ios')}*
radio	**Format:** *${ask('message', radio, ('real_value1':'rendered_value1';...;'real_valueN':'rendered_valueN'), 'default')}*

Parameter	
	Description: Displays a dialog box that offers a series of radio buttons. Each radio button displays a *'rendered_value* and will return an associated *real_value*. **Note:** The list of *'real_value':'rendered_value'* pairs can be computed using *${xpath_eval()}*. **Note:** The *'default'* parameter specifies the default-selected value and can match either a key or a value. **Example:** ▪ *${ask('Operating System', radio, ('win':'Microsoft Windows';'macos':'macOS';'lnx':'Linux/UNIX'), 'macos')}* - The dialog box has the name *'Operating System'*. The radio button group allows you to choose between the three operating systems. **Note:** In this example, `macOS` is the default-selected value and if selected, it would return *macos* for the output. ▪ *${ask('Operating System', radio, (${xpath_eval(for $pair in (['win', 'Microsoft Windows'], ['macos', 'macOS'], ['lnx', 'Linux/UNIX']) return '"' || $pair?1 || '":"' || $pair?2 || '";')}), 'ios')}*

- **${timeStamp}** - The timestamp, which is the current time in Unix format. For example, it can be used to save transformation results in multiple output files on each transformation.
- **${uuid}** - Universally unique identifier, a unique sequence of 32 hexadecimal digits generated by the Java UUID class.
- **${id}** - Application-level unique identifier. It is a short sequence of 10-12 letters and digits that is not guaranteed to be universally unique.
- **${cfn}** - Current file name without the extension and parent folder. The current file is the one currently open and selected.
- **${cfne}** - Current file name with extension. The current file is the one currently open and selected.
- **${cf}** - Current file as file path, that is the absolute file path of the currently edited document.
- **${cfd}** - Current file folder as file path, that is the path of the currently edited document up to the name of the parent folder.

- **${frameworksDir}** - The path (as file path) of the `frameworks` directory. When used to define references inside a framework configuration, it expands to the parent folder of that specific framework folder. Otherwise, it expands to the main `frameworks` folder defined in the **Document Type Association > Locations** preferences page.
- **${pd}** - The file path to the folder that contains the current project file (`.xpr`).
- **${oxygenInstallDir}** - Oxygen XML Editor installation folder as file path.
- **${homeDir}** - The path (as file path) of the user home folder.
- **${pn}** - Current project name.
- **${env(VAR_NAME)}** - Value of the *VAR_NAME* environment variable. The environment variables are managed by the operating system. If you are looking for Java System Properties, use the **${system(var.name)}** editor variable.
- **${system(var.name)}** - Value of the *var.name* Java System Property. The Java system properties can be specified in the command-line arguments of the Java runtime as *-Dvar.name=var.value*. If you are looking for operating system environment variables, use the **${env(VAR_NAME)}** editor variable instead.
- **${date(pattern)}** - Current date. The allowed patterns are equivalent to the ones in the Java SimpleDateFormat class. **Example:** *yyyy-MM-dd*.

> **Note:**
> This editor variable supports both the **xs:date** and **xs:datetime** parameters. For details about **xs:date**, go to: http://www.w3.org/TR/xmlschema-2/#date. For details about **xs:datetime**, go to: http://www.w3.org/TR/xmlschema-2/#dateTime.

How to Find More Information About the Arguments of an Operation

If you need to find more information about the arguments of an operation, there are several places where this information is available:

- In the API documentation for the particular operation.
- By invoking the `getArguments()` method on the operation.
- In the source code of the operation.
- In Oxygen XML Editor:
  1. Go to **Options > Preferences > Document Type Association**, select a document type and click the **New**, **Edit**, **Duplicate**, or **Extend** button *(on page 145)*.
  2. Go to the **Author** tab and then the **Actions** subtab. At the bottom of this subtab, click **New** to open the **Action** dialog box *(on page 155)*.
  3. Locate the **Operation** field and click the **Choose** button on the right side. This will open a dialog box that displays the default operations.
  4. Double-click the operation (or select it and click **OK**).

     The arguments for the operation will now be displayed in the **Action** dialog box *(on page 155)*.

Arguments of InsertFragmentOperation

fragment

This argument has a textual value. This value is parsed by Oxygen XML Editor as it was already in the document at the cursor position. You can use entity references declared in the document and it is namespace aware. The fragment may have multiple roots.

You can even use namespace prefixes that are not declared in the inserted fragment, if they are declared in the document where the insertion is done. For the sake of clarity, you should always prefix and declare namespaces in the inserted fragment!

If the fragment contains namespace declarations that are identical to those found in the document, the namespace declaration attributes will be removed from elements contained by the inserted fragment.

There are two possible scenarios:

- **Prefixes that are not bound explicitly**

  For instance, the fragment:

```
<x:item id="dty2"/>
&ent;
<x:item id="dty3"/>
```

  Can be correctly inserted in the document: ('|' marks the insertion point):

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE x:root [
    <!ENTITY ent "entity">
]>

<x:root xmlns:x="nsp">
  |
</x:root>
```

  Result:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE x:root [
    <!ENTITY ent "entity">
]>
<x:root xmlns:x="nsp">
    <x:item id="dty2"/>
    &ent;
    <x:item id="dty3"/>
</x:root>
```

- **Default namespaces**

  If there is a default namespace declared in the document and the *document fragment (on page 3419)* does not declare a namespace, the elements from the fragment are considered to be in **no namespace**.

  For instance, the fragment:

  ```
  <item id="dty2"/>
  <item id="dty3"/>
  ```

  Inserted in the document:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  <root xmlns="nsp">
  |
  </root>
  ```

  Gives the result document:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  <root xmlns="nsp">
      <item xmlns="" id="dty2"/>
      <item xmlns="" id="dty3"/>
  </root>
  ```

insertLocation

An XPath expression that is relative to the current node. It selects the reference node for the fragment insertion. When missing, the fragment will be inserted at the cursor position.

insertPosition

Specifies where the insertion is made relative to the reference node selected by the *insertLocation*. It can be one of the following constants:

- **Inside as first child** (default value) - The fragment is inserted as first child of the reference node.
- **Inside as last child** - The fragment is inserted as the last child of the reference node.
- **After** - The fragment is inserted after the reference node.
- **Before** - The fragment is inserted before the reference node.

goToNextEditablePosition

After inserting the fragment, the first editable position is detected and the cursor is placed at that location. It handles any in-place editors used to edit attributes. It will be ignored if the fragment specifies a cursor position using the **${caret}** editor variable *(on page 338)*. The possible values of this action are **true** and **false**.

schemaAware

This argument applies only on the surround with element operation and controls whether or not the insertion is valid, based upon the schema. If the insertion is not valid, then wrapping action will be broken up into smaller intervals until the wrapping action is valid. For example, if you try to wrap a *paragraph* element with a *bold* element, it would not be valid, so the operation will wrap the text inside the paragraph instead, since it would be valid at that position.

insertEvenIfInvalid

The possible values of this argument are **true** and **false**. If **true**, the content that would make the document invalid is accepted. If **false** and the insertion is not valid, the operation will not be executed and an error message will be displayed.

Arguments of SurroundWithFragmentOperation

fragment

The XML fragment that will surround the selection. For example, consider the fragment:

```
<F>
   <A></A>
   <B>
     <C></C>
   </B>
</F>
```

and the document:

```
<doc>
  <X></X>
  <Y></Y>
  <Z></Z>
<doc>
```

Considering the selected content to be surrounded is the sequence of elements `X` and `Y`, then the result is:

```
<doc>
   <F>
      <A>
         <X></X>
         <Y></Y>
      </A>
      <B>
        <C></C>
      </B>
   </F>
```

```
  <z></z>
<doc>
```

Since the element `A` was the first leaf in the fragment, it received the selected content. The fragment was then inserted in the place of the selection.

Note:
If the first leaf is not the desired location for the surrounded fragment, you can use ro.sync.ecss.extensions.commons.operations.InsertOrReplaceFragmentOperation and set the following arguments:

fragment

The XML fragment that will surround the selection. Use the `${selection}` editor variable in the location you want to place the surrounded fragment.

schemaAware

Set it to *false* to avoid moving the fragment if it is not valid at the given location.

schemaAware

This argument applies only on the surround with element operation and controls whether or not the insertion is valid, based upon the schema. If the insertion is not valid, then wrapping action will be broken up into smaller intervals until the wrapping action is valid. For example, if you try to wrap a *paragraph* element with a *bold* element, it would not be valid, so the operation will wrap the text inside the paragraph instead, since it would be valid at that position.

Note:
If a selection exists, the surround with fragment operation is not schema aware.

Adding a Custom Operation to an Existing Framework

This task explains how to add a custom **Author** mode operation to an existing *framework (on page 3420)* (document type).

1. Set up a sample project by following the instructions for installing the SDK.

   Tip:
   The SDK contains a sample *framework* project called `oxygen-sample-framework`.

2. A variety of classes in the *simple.documentation.framework.operations* package implement the *ro.sync.ecss.extensions.api.AuthorOperation* interface. Depending on your use-case, modify one of these classes.
3. Pack the operation class inside a Java *JAR* library.

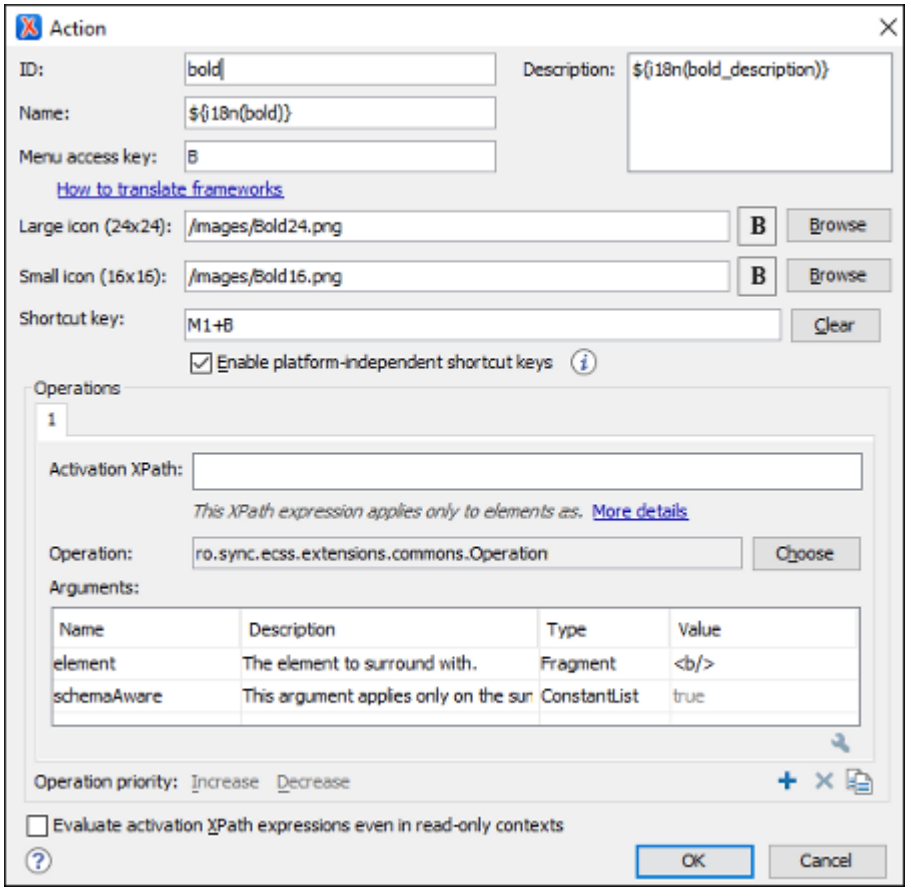
4. Copy the *JAR* library to your framework directory (for example, `[OXYGEN_INSTALL_DIR]/frameworks/[FRAMEWORK_DIR]`).
5. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, and edit the document type (you need write access to the `[OXYGEN_INSTALL_DIR]`) to open the **Document Type** configuration dialog box *(on page 147)*.
    a. In the **Classpath** tab, add a reference to your JAR library (for example, `${framework}/customAction.jar`).
    b. Go to the **Author** tab, then go to the **Actions** subtab.
    c. Click the **New** button and use the **Action** dialog box *(on page 155)* to create a new action that uses your custom operation.
    d. Mount the action to the toolbars or menus. You can also define a shortcut key.
6. Share the modifications *(on page 2406)* with your colleagues. The files that should be shared are your `customAction.jar` library and the `.framework` configuration file from the `[OXYGEN_INSTALL_DIR]/frameworks/[FRAMEWORK_DIR]` directory.

Related Information:
AuthorOperation API

Example: Configuring the Insert Section Action for a Framework

This topic describes the procedure for defining the **Insert Section** action for a custom *framework (on page 3420)*. It is assumed that the icon files,  (`Section16.gif`) for the menu item and  (`Section20.gif`) for the toolbar, are already available. Although you could use the same icon size for both the menu and toolbar, usually the icons from the toolbars are larger than the ones found in the menus. These files should be placed in your custom *framework* directory (`[OXYGEN_INSTALL_DIR]\frameworks\[CUSTOM_FRAMEWORK_DIR]`).

Figure 586. Action Dialog Box



1. Set the **ID** field to **insert_section**. This is a unique action identifier.
2. Set the **Name** field to **Insert Section**. This will be the action's name, displayed as a tooltip when the action is placed in the toolbar, or as the menu item name.
3. Set the **Menu access key** to **i**. On Windows, the menu items can be accessed using **Alt+letter** keys combination, when the menu is visible. The *letter* is visually represented by underlining the first letter from the menu item name having the same value.
4. Add a **Description**.
5. Set the **Large icon (20x20)** field to `${framework}/Section20.gif`. A good practice is to store the image files inside the *framework* directory and use editor variable *(on page 332)* **${framework}** to make the image relative to the *framework* location.
   If the images are bundled in a *JAR (on page 3420)* archive together with some Java operations implementation, for instance, it might be convenient for you to reference the images not by the file name, but by their relative path location in the class-path.

   If the image file `Section20.gif` is located in the **images** directory inside the *JAR* archive, you can reference it by using **/images/Section20.gif**. The *JAR* file must be added into the **Classpath** list.
6. Set the **Small icon (16x16)** field to `${framework}/Section16.gif`.
7. Click the text field next to **Shortcut key** and set it to **Ctrl+Shift+S (Meta+Shift+S on macOS)**. This will be the key combination to trigger the action using the keyboard only.
   The shortcut is enabled only by adding the action to the main menu of **Author** mode *(on page 2299)*, which contains all the actions that the author will have in a menu for the current document type.

8. At this time the action has no functionality added to it. Next you must define how this action operates. An action can have multiple operation modes. The first action mode enabled by the evaluation of its associated XPath expression will be executed when the action is triggered by the user. The XPath expression needs to be version 2.0 and its scope must be only element and attribute nodes of the edited document. Otherwise, the expression will not return a match and will not trigger the action. If the expression is left empty, the action will be enabled anywhere in the scope of the root element. For this example, suppose you want the action to add a section only if the current element is either a `<book>`, `<article>`, or another `<section>`.

    a. Set the XPath expression field to:

    ```
    local-name()='section' or local-name()='book' or
     local-name()='article'
    ```

    b. Set the **invoke operation** field to *InsertFragmentOperation* built-in operation, designed to insert an XML fragment at the cursor position. This belongs to a set of built-in operations, a complete list of which can be found in the Author Default Operations *(on page 2269)* section. This set can be expanded with your own Java operation implementations.

    c. Configure the arguments section as follows:

    ```
    <section xmlns=
    "http://www.oxygenxml.com/sample/documentation">
         <title/>
    </section>
    ```

    `insertLocation` - leave it empty. This means the location will be at the cursor position.

    `insertPosition` - select "**Inside**".

Example: Configuring the Insert Table Action for a Framework

This topic describes the procedure for defining the **Insert Table** action for a custom *framework (on page 3420)*. Suppose that you want to create an action that inserts a table with three rows and three columns into a document and the first row is the table header. As with the insert section action *(on page 2296)*, you will use the *InsertFragmentOperation* built-in operation.

Place the icon files for the menu item, and for the toolbar, in your custom *framework* directory (*[OXYGEN_INSTALL_DIR]*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).

1. Set **ID** field to **insert_table**.
2. Set **Name** field to **Insert table**.
3. Set **Menu access key** field to **t**.
4. Set **Description** field to **Adds a table element**.
5. Set **Toolbar icon** to **${framework} / toolbarIcon.png**.
6. Set **Menu icon** to **${framework} / menuIcon.png**.
7. Set **Shortcut key** to **Ctrl + Shift + T (Command + Shift + T on macOS)**.

8. Set up the action's functionality:

    a. Set **XPath expression** field to `true()`.
    `true()` is equivalent with leaving this field empty.

    b. Set **Invoke operation** to use **InsertFragmentOperation** built-in operation that inserts an XML fragment to the cursor position.

    c. Configure operation's arguments as follows:

    fragment - set it to:

    ```
    <table xmlns=
    "http://www.oxygenxml.com/sample/documentation">
      <header><td/><td/><td/></header>
      <tr><td/><td/><td/></tr>
      <tr><td/><td/><td/></tr>
    </table>
    ```

    `insertLocation` - to add tables at the end of the section use the following code:

    ```
    ancestor::section/*[last()]
    ```

    `insertPosition` - Select **After**.

Using Retina/HiDPI Icons for the Actions from a Framework

Higher resolution icons can also be included in customized *frameworks (on page 3420)* for rendering them in a Retina or HiDPI display. The icons can be referenced directly from the **Document Type Congifuration** dialog box *(on page 147)* (from the **Action** dialog box *(on page 155)*) or from an API (*ro.sync.exml.workspace.api.node.customizer.XMLNodeRendererCustomizer (on page 2387)*).

As with any image, the higher resolution icons are stored in the same images folder as the normal resolution images and they are identified by a scaling factor that is included in the name of the image files. For instance, icons with a Retina scaling factor of 2 will include *@2x* in the name (for example, `myIcon@2x.png`).

Developers should not specify the path of the alternate icons (*@2x* or *@3x*) in the **Action** dialog box *(on page 155)* or the *XMLNodeRendererCustomizer* API *(on page 2387)*. When using a Retina or HiDPI display, Oxygen XML Editor automatically searches the folder of the *normal* icon for a corresponding image file with a Retina scaling factor in the name. If the higher resolution icon file does not exist, the *normal* icon is scaled and used instead.

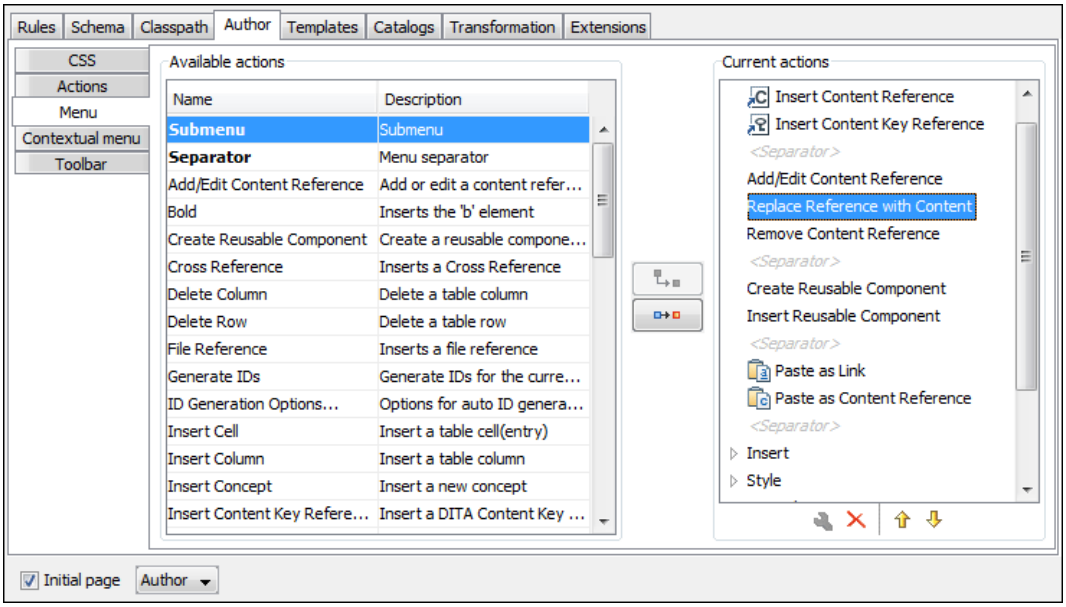
Related Information:
Retina/HiDPI Images in Author Mode *(on page 734)*

Customizing the Menu for a Framework

Defined actions can be grouped into customized menus in the Oxygen XML Editor menu bar.

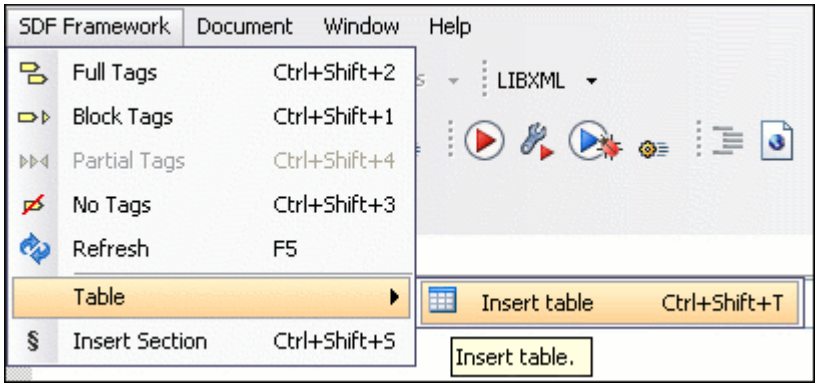
1. Open the **Document Type** configuration dialog box *(on page 147)*, select your custom *framework (on page 3420)*, and go to the **Author** tab.
2. Go to the **Menu** subtab. In the left side you have the list of actions and some special entries:
   - **Submenu** - Creates a submenu. You can nest an unlimited number of menus.
   - **Separator** - Creates a separator into a menu. This way you can logically separate the menu entries.
3. The right side of the panel displays the current actions for that menu tree. To change its name, click this label to select it, then click the **Edit** button.
4. Select the **Submenu** label in the left panel section and the appropriate label in the right panel section, then click the **Add as child** button. Change the submenu name to **Table**, using the **Edit** button.
5. Select the **Insert section** action in the left panel section and the **Table** label in the right panel section, then click the **Add as sibling** button.
6. Now select the **Insert table** action in the left panel section and the **Table** in the right panel section. Click the **Add as child** button.

Figure 587. Configuring the Menu



When opening a test document for a custom *framework* in **Author** mode, the menu you created is displayed in between the **Tools** and the **Document** menus. The upper part of the menu contains generic **Author** mode actions (common to all document types) and the two actions created previously (with **Insert table** under the **Table** submenu).

Figure 588. Author Mode Menu



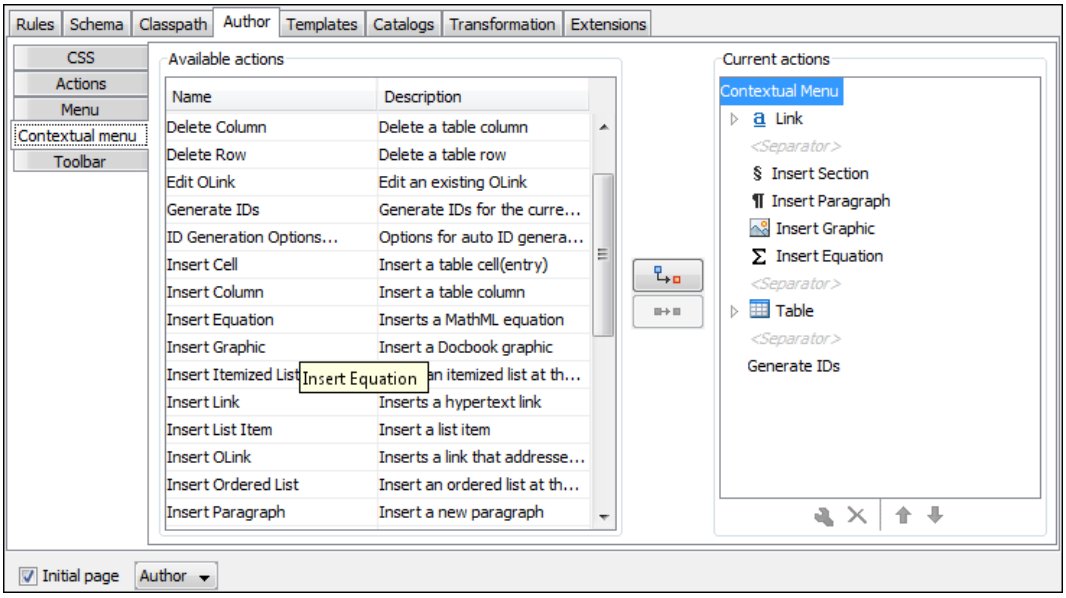
Customizing the Contextual Menu for a Framework

The contextual menu is displayed when you right-click in the **Author** editing area. You can only configure the bottom part of the menu, since the top part is reserved for a list of generic actions (such as Copy, Paste, Undo, etc.)

1. Open the **Document Type** configuration dialog box *(on page 147)* for the particular *framework (on page 3420)* and go to the **Author** tab. Next, go to the **Contextual Menu** subtab.
2. Follow the same steps as explained in the Configuring the Main Menu *(on page 2299)*, except changing the menu name because the contextual menu does not have a name.

> **Note:**
> You can choose to reuse a submenu that contains general authoring actions. In this case, all actions (both general and *framework*-specific ones) are grouped together under the same submenu.

Figure 589. Configuring the Contextual Menu



To test it, open the test file, and open the contextual menu. In the lower part there is shown the **Table** sub-menu and the **Insert section** action.

Customizing the Content Completion Assistant for Author Mode Only

You can customize the content of the following **Author** controls, adding items (which, when invoked, perform custom actions) or filtering the default contributed ones:

- *Content Completion Assistant (on page 3418)* window
- **Elements** view *(on page 643)*
- **Insert Element** menus (from the **Outline** view *(on page 549)* or breadcrumb *(on page 612)* contextual menus)

You can use the content completion customization support in a custom *framework (on page 3420)* by following this procedure:

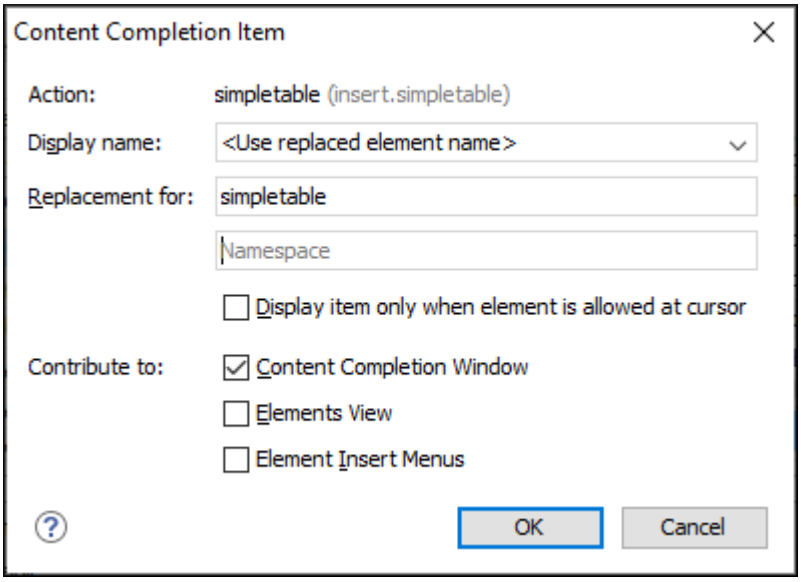
1. Open the **Document type** configuration dialog box *(on page 147)* for your custom *framework* and select the **Author** tab. Next, go to the **Content Completion** tab *(on page 167)*.

   Figure 590. Customize Content Completion

   
   The top side of the **Content Completion** section contains the list with all the actions defined within the custom *framework* and the list of actions that you decided to include in the *Content Completion Assistant* list of proposals. The bottom side contains the list with all the items that you decided to remove from the *Content Completion Assistant* list of proposals.

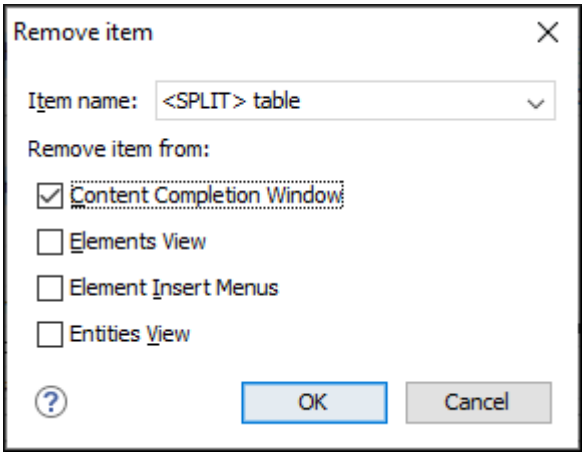
2. If you want to add a custom action to the list of current **Content Completion** proposals, select the action item from the **Available actions** list and click the **Add as child** or **Add as sibling** button to include it in the **Current actions** list. A **Content Completion Item** dialog box appears, giving you the possibility to select where to provide the selected action.

Figure 591. Content Completion Item Dialog Box



3. If you want to exclude a certain item from the **Content Completion** proposals, you can use the **Add** button from the **Filter - Remove content completion items** list. The **Remove item** dialog box is displayed, allowing you to input the item name and to choose the controls that filter it. The **Item name** combo box accepts wildcards.

Figure 592. Remove Item Dialog Box



Note:
In the **Item name** drop-down menu, **<SPLIT>** refers to the action of splitting the element and creating a new one, while **<ENTER>** refers to the action of inserting a new line.

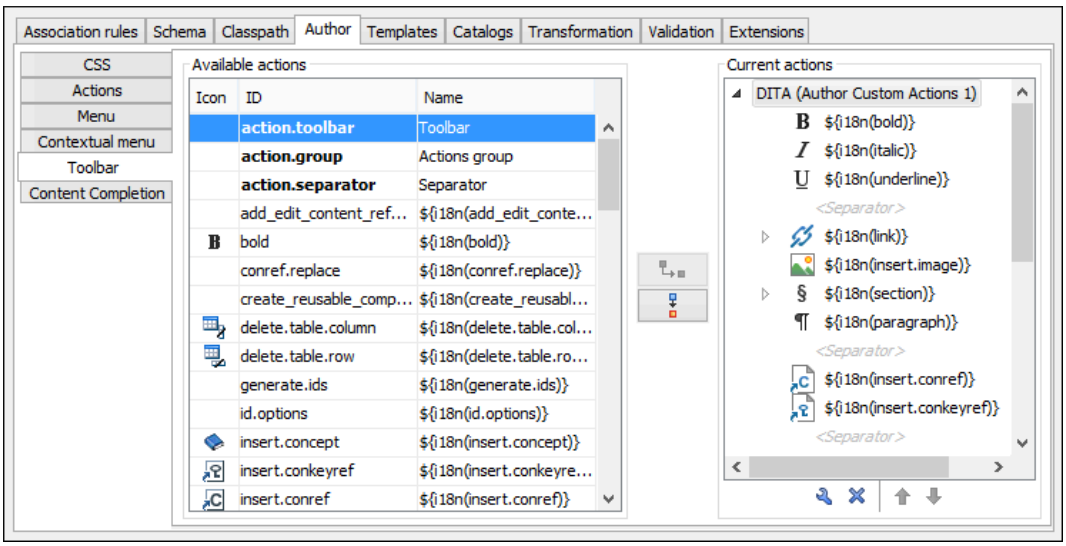
Customizing the Content Completion Assistant Using a Configuration File *(on page 2309)*

Customizing the Toolbars for a Framework

This procedure describes how to add defined actions to a toolbar for a custom *framework (on page 3420)*. You can also create additional custom toolbars with existing or custom actions.

1. Open the **Document Type** configuration dialog box *(on page 147)* for your custom *framework* and select the **Author** tab.
2. Go to the **Toolbar** subtab.

Figure 593. Configuring the Toolbar



The panel is divided in two sections. The left side contains a list of actions, while the right side contains an action tree, displaying the list of actions added in the toolbar. The special entry called *Separator* allows you to visually separate the actions in the toolbar.

3. To add an action, select it in the left panel and select the particular toolbar label where you want it added in the right panel section, then click the **Add as child** or **Add as sibling** button.

Result: When opening a document for the particular *framework* in **Author** mode, the toolbar with the new buttons will be displayed in the toolbar area.

Tip:
If you have many custom toolbar actions, or want to group actions according to their category, add more toolbars with custom names and split the actions to better suit your purpose. If your toolbar is not displayed when switching to the **Author** mode, right-click the main toolbar, select **Configure Toolbars**, and make sure the appropriate toolbar (such as the **Author Custom Actions** toolbar) is selected.

Note:
A maximum of 16 toolbars can be added. If you add more, all extra toolbars will be automatically converted to sub-toolbars for the last added toolbar.

Customizing Text-to-Markup Shortcut Patterns

Some built-in frameworks include a configuration file that defines shortcut patterns that can be used in **Author** mode to automatically insert a certain XML structure. More specifically, the XML structure (fragment) automatically replaces a specific prefix pattern. For example, if you are editing a DITA document using the built-in DITA framework, entering a hyphen (**-**) followed by a space at the beginning of a paragraph would automatically replace them with an unordered list element (`<ul>`) with a child list item element (`<li>`). This is made possible by the *AutoCorrect* mechanism in Oxygen XML Editor.

It is possible to customize the particular configuration file (`structureAutocorrect.xml`) to define your own markup insertion shortcut patterns by following these steps:

1. Create a new `resources` folder (if it does not already exist) in the `frameworks` directory for the particular document type (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources`).
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association**. Select the particular document type, click the **Edit** button, and in the **Classpath** tab *(on page 152)* add a link to that `resources` folder (if it does not already exist).
3. Create a new `structureAutocorrect.xml` file or edit an existing one (this file already exists in the `resources` folder of particular document types and you can use an existing file as a starting point for your customization).
4. Make the appropriate changes to your `structureAutocorrect.xml` file. The file should look like this:

```
<structure-autocorrect>
  <!-- Unordered lists -->
  <prefix-replacement prefix="-">
    <ul><li/></ul>
  </prefix-replacement>
  <!-- Ordered lists -->
  <prefix-replacement prefix="1.">
    <ol><li/></ol>
  </prefix-replacement>
  <!-- Code block -->
  <prefix-replacement prefix="```">
    <codeblock/>
  </prefix-replacement>
</structure-autocorrect>
```

Using this example, when a user enters one of the defined prefixes at the start of an element that allows the corresponding fragment, Oxygen XML Editor will automatically replace the prefix with its corresponding fragment. For example, entering a hyphen (**-**) at the beginning of a paragraph followed by a space would automatically replace them with an unordered list element (`<ul>`) with a child list item element (`<li>`). Any subsequently added content would be placed inside the first node/element that does not have a child node/element (in this example, the cursor would be placed in the first `<li>` element).

5. Save the file in the `resources` folder for the particular document type, using the fixed name: `structureAutocorrect.xml` (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/structureAutocorrect.xml`).
6. Restart the application and open a document for your particular framework to test your customization.

> **Note:**
> Once the file is created, changes that you make to it are processed by Oxygen XML Editor when you press the **Reload** toolbar button.

Customizing Smart Paste Support

The *Smart Paste* feature *(on page 623)* preserves certain style and structure information when copying content from some of the most common applications and pasting into *frameworks* (document types) that support *Smart Paste (on page 624)* in Oxygen XML Editor. For other document types, the default behavior of the paste operation is to keep only the text content without the styling.

The style of the pasted content can be customized by editing an XSLT stylesheet for a particular document type (*framework (on page 3420)*). The XSLT stylesheet must accept an XHTML flavor of the copied content as input, and transform it to the equivalent XML markup that is appropriate for the target document type of the paste operation.

How to Customize the Smart Paste Mapping

To customize the mapping between the markup of the copied content and the markup of the pasted content for a particular document type, follow these steps:

1. Make sure the particular *framework* contains a folder named `resources` in the following path structure:

   ```
   /frameworks/[Document Type]/resources
   ```

2. Create an XSLT file named `xhtml2content.xsl` and save it in the `resources` folder for the particular *framework*.

   For example: `/frameworks/[Document Type]/resources/xhtml2content.xsl`

3. Add your customized styling in the XSLT file. A list of supported parameters can be found in the Supported Parameters for the Custom Smart Paste XSLT *(on page 2308)* section below.

> **Tip:**
> The built-in DITA framework includes an `xhtml2ditaDriver.xsl` file (in *`[OXYGEN_INSTALL_DIR]`*`/frameworks/dita/resources`) that imports various other stylesheets that apply cleanup and handle the conversion from the pasted HTML content to DITA. If you are using a custom extension of the DITA framework, you can copy the entire contents of the built-in `dita/resources` folder and customize the stylesheets according to your needs.

4. You can test modifications done in the stylesheet by pasting content without having to restart Oxygen XML Editor.

Result: When you paste content from external applications (such as a web browser or and Office document) to a document that is open in **Author** mode, and that matches the particular *framework*, the styling from the `xhtml2content.xsl` stylesheet will be applied on the clipboard contents.

Customized Smart Paste Stylesheet Sample:

```
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xhtml="http://www.w3.org/1999/xhtml"
  xmlns="urn:hl7-org:v3"
  exclude-result-prefixes="xsl xhtml">

  <xsl:output method="xml" indent="no" omit-xml-declaration="yes"/>

  <xsl:template match="xhtml:b | xhtml:strong">
    <content styleCode="bold" >
      <xsl:apply-templates select="@* | node()"/>
    </content>
  </xsl:template>

  <xsl:template match="*">
    <xsl:apply-templates select="@* | node()"/>
  </xsl:template>

  <xsl:template match="@* | node()">
    <xsl:copy>
      <xsl:apply-templates select="@* | node()"/>
    </xsl:copy>
  </xsl:template>

</xsl:stylesheet>
```

Supported Parameters for the Custom Smart Paste XSLT

The following parameters can be used in your XSLT stylesheet for customizing the *Smart Paste* mechanism:

inTableContext

The custom XSLT stylesheet receives this parameter with a value of **true** if the end-user is pasting content inside a table.

folderOfPasteTargetXml

A URL pointing to the folder where the currently edited XML document is located. This is used to save images relative to the current XML document.

context.path.names

A sequence of element names showing the current context in the XML document where the paste occurred.

context.path.uris

A sequence of namespaces, one for each context path name.

context.path.separator

The separator between the path names. Its value can be used to split the context path names to a sequence.

By default, there is an extra check in place to ensure that the applied XSLT does not remove the original text from the pasted content. If there is a file called `externalPasteOptions.xml` in the `resources` folder, you can use it to specify the default behavior for checking if the XSLT stylesheet loses content during conversion:

```
<!-- Options that control external paste
(automatic conversions when pasting HTML and URL flavors from the clipboard). -->
<pasteOptions>
    <!-- True to check if the entire sequence of words which get pasted are
         converted to the target vocabulary. If the check fails, the content
         will be inserted as a simple sequence of words without any formatting. -->
    <checkEntireContentIsFullyPreserved>true</checkEntireContentIsFullyPreserved>
</pasteOptions>
```

Customize the Content Completion Assistant

Oxygen XML Editor gathers information from the associated schemas (DTDs, XML Schema, RelaxNG) to determine the proposals that appear in the *Content Completion Assistant (on page 3418)*. Oxygen XML Editor

also includes support that allows you to customize the *Content Completion Assistant* to suit your specific needs.

There are two ways to customize the *Content Completion Assistant* in Oxygen XML Editor:

- You can add, modify, or remove actions that are proposed for each particular document type (*framework (on page 3420)*) by using the **Content Completion** subtab in the **Document Type Association** configuration dialog box *(on page 167)*. To access this subtab, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, use the **New**, **Edit**, **Duplicate**, or **Extend** button *(on page 145)*, click on the **Author** tab, and then the **Content Completion** subtab.

  Note:
  This works only for Author visual mode.

- You can use a `cc_config.xml` configuration file that is specific to each document type (*framework*) to configure the values that are proposed in certain contexts, to customize the attributes or elements that are proposed, or to customize how certain aspects of the proposals are rendered in the interface. The rest of the topics in this section explain how you can use this configuration file to customize the content completion.

Configuring the Proposals for Elements and Attributes

There are many cases where elements have a relaxed content model and can accept a large number of child elements. For example, the DITA list item element (`<li>`) accepts more than 60 child elements. Oxygen XML Editor includes support to allow the content architect to put some constraints on the possible elements or attributes, or to impose some best practices in the way content is edited.

For an example of a specific use-case, suppose that you want to restrict DITA list item elements (`<li>`) to only accept paragraph elements (`<p>`). In this case, the *Content Completion Assistant (on page 3418)* should not offer any element other than a paragraph (`<p>`) when a list item (`<li>`) is inserted into a document. It would also be helpful if the required child element (`<p>`) was automatically inserted whenever a list item (`<li>`) is inserted.

One method of changing the content model is to alter the element definition in the associated schema (XML Schema, DTD, RelaxNG), but this may be complicated in some cases. Fortunately, Oxygen XML Editor offers a simple, alternative method of using a configuration file to customize the content completion proposals for each element.

Setting up the Content Completion Configuration File

To customize the configuration file for the *Content Completion Assistant (on page 3418)*, follow these steps:

1. Create a new `resources` folder (if it does not already exist) in the `frameworks` directory for the particular document type (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources`).
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association**. Select the particular document type, click the **Edit** button, and in the **Classpath** tab *(on page 152)* add a link to that `resources` folder (if it does not already exist).
3. Create a new configuration file or edit an existing one.

a. To easily create a new configuration file, you can use the *Content Completion Configuration* document template that is included in Oxygen XML Editor (**File > New > Framework templates > Oxygen Extensions > Content Completion Configuration**). The document template includes details about how each element and attribute is used in the configuration file.
b. If a configuration file (`cc_config.xml`) already exists for the particular document type (in the `resources` folder), you can modify this existing file.
c. If you extend a framework, you need to copy the content of the `cc_config.xml` file from the base framework and modify it (e.g. create a `resources` folder in your framework extension folder and place the file there). You also need to make sure that the folder that contains the `cc_config.xml` file in your extension (e.g. `resources`) is listed in the **Classpath** tab *(on page 152)* before the one from the base framework.

   If you only want to make small changes or add extra rules in your custom content completion configuration file, you need to name it `cc_config_ext.xml` and all the rules inside it are merged with the base `cc_config.xml` file. The merging is done by taking all the rules specified in the `cc_config_ext.xml` file into consideration after processing the set of rules from the base `cc_config.xml` file.

4. Make the appropriate changes to your custom configuration file.
5. Save the file in the `resources` folder for the particular document type, using the fixed name: `cc_config.xml` (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/cc_config.xml`).
6. Restart the application and open an XML document. In the *Content Completion Assistant* you should see your customizations.

Tip:
In some cases, you can simply use the **Refresh (F5)** action to test your customizations, without having to restart the application.

Attention:
In the **Classpath** tab *(on page 152)*, if you have references to multiple `resources` folders, each with its own `cc_config.xml` file, the first reference listed in the **Classpath** tab takes precedence and the multiple configuration files are not combined.

Configuring Elements or Attributes that are Proposed for Each Element

For the purposes of customizing the elements or attributes that are proposed for each individual element, the configuration file (`cc_config.xml`) uses `<elementProposals>` elements. This element allows you to customize or filter the child elements and attributes for an element.

Warning:
Note that you can only choose elements or attributes that are already allowed by the schema in a particular context. For example, you cannot specify an element that is not allowed by the schema as a child of a particular node.

Elements:

To control the **elements** that are proposed for an element, you can use the following attributes for the `<elementProposals>` element:

- **path** - A path within the document that matches the element that will have its content completion proposals changed. For example, `"title"` matches all the `<title>` elements in the document, while `"chapter/title"` matches only the `<title>` elements that are direct children of the `<chapter>` element. You can use simplified forms of XPath in this attribute.

  The XPath expressions can accept multiple attribute conditions and inside each condition you can use *AND/OR* boolean operators and parentheses to override the priority.

  You can use one or more of the following attribute conditions (default attribute values are not taken into account):
  - *element[@attr]* - Matches all instances of the specified element that include the specified attribute.
  - *element[not(@attr)]* - Matches all instances of the specified element that do not include the specified attribute.
  - *element[@attr = "value"]* - Matches all instances of the specified element that include the specified attribute with the given value.
  - *element[@attr != "value"]* - Matches all instances of the specified element that include the specified attribute and its value is different than the one given.

  Example: The following are examples of how you could use multiple boolean operators and parentheses inside an attribute condition:

  ```
  *[@a and @b or @c and @d]
  *[@a and (@b or @c) and @d]
  ```

  The following are just examples of how simplified XPath expressions might look like:
  - *elementName*
  - *//elementName*
  - */elementName1/elementName2/elementName3*
  - *//xs:localName*
  - *//xs:documentation[@lang="en"]*

  Note:
  Using a namespace prefix requires that you declare it on the `<elementProposals>` element or on an ancestor element. For example:

```
<elementProposals xmlns:db5="http://docbook.org/ns/docbook"
  path="db5:listitem" insertElements="db5:para" />
```

Other Important Notes:

- If the `@path` attribute is missing, the customization will apply to the proposals for all elements. You can intentionally omit this attribute and use *possibleElements (on page 2313)* or *rejectElements (on page 2314)* to specify or restrict particular elements for a *framework (on page 3420)*.

  For example, suppose that in your DITA documents, you want to restrict your users from using `<image>` and `<fig>` elements because you do not want images to be included in your output. The configuration file should look like this:

  ```
  <elementProposals rejectElements="image fig" />
  ```

  Since the `@path` attribute is missing, the specified element will be filtered out from the proposals for the entire *framework*.

- If the particular document type has name namespaces, the `@path` should contain the qualified name. For example, in TEI documents, if you want to set a list of possible attributes for the `<span>` element, you need to use a qualified name like this (notice the declaration of the namespace prefix "*t*" and its usage):

  ```
  <config xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.oxygenxml.com/ns/ccfilter/config
       http://www.oxygenxml.com/ns/ccfilter/config/ccConfigSchemaFilter.xsd"
      xmlns="http://www.oxygenxml.com/ns/ccfilter/config"
      xmlns:t="http://www.tei-c.org/ns/1.0">

      <elementProposals path="t:span" possibleAttributes="type"/>
  ```

- **insertElements** - A space-separated sequence of child element names. Each time the element specified in the `@path` attribute is inserted into the document, these child elements will also be inserted in the order that they are listed. For example, `insertElements="b i"` will insert exactly one `<b>` element, followed by an `<i>` element. An empty value (`""`) means that no child elements should be inserted.

  Note:
  If this attribute is missing, the default required child elements will be inserted, as specified in the associated schema for the document.

- **possibleElements** - A space-separated list of element names that will be shown in the content completion list when invoked inside an element that is specified in the `@path` attribute. For example, `"b i codeph ph"` means that the *Content Completion Assistant* will contain these four elements when

invoked on the element specified in the `@path` attribute. The following other possible values are also supported:

- ***NONE*** - There will be no proposals in the content completion list.
- ***ALL*** - All the possible elements specified in the associated schema will be presented in the content completion list. This is also the default behavior if this attribute is missing.
- ***INSERTED*** - The proposals will be the same list of elements that are defined in the `@insertElements` attribute.

When using this attribute to specify multiple elements, only use one entry with the element names separated by a space:

```
<elementProposals possibleElements="b i codeph ph" />
```

- **rejectElements** - A space-separated list of element names that will be filtered out from the list of proposals that are presented in the content completion list. Each time the element specified in the `@path` attribute is inserted into the document, the list of proposals in the *Content Completion Assistant* will include the entries that are defined in the associated schema, minus the elements specified in this attribute.

  Note:

  This setting makes the application behave as if the rejected elements were not allowed by the schema in that location. Most of the toolbar actions take the schema into account when inserting content. If the inserted content is not allowed by the schema in that particular location, the application tries to find another location within close proximity where the content is allowed.

  For example, suppose you reject the insertions of images in paragraphs. If a user has the cursor inside a paragraph and uses the toolbar action that inserts an image, the image will be inserted after the current paragraph rather than at the current location.

  If you want to avoid having users insert an element directly from the content completion mechanism and want them to use a toolbar action instead, it is better to use the Document Type Configuration *(on page 167)* dialog box to remove the element.

  When using this attribute to specify multiple elements, only use one entry with the element names separated by a space:

  ```
  <elementProposals rejectElements="image fig imagemap foreign" />
  ```

- **contentType** - Forces an element to have an imposed content type. The possible values are: `elementOnly`, `mixed`, or `empty`.

  ```
  <elementProposals path="section" insertElements="title p" contentType="elementOnly"/>
  ```

- **merge** - By default, if there are multiple element proposal rules that match the current element context, then only the rule that has the most specific path is used. By setting the `@merge` attribute to `true` on the proposal rules that might match the same element context, all the rules will be applied. Example:

```
<elementProposals
  path="/*[not(@xml:lang='ja')]//*"
  rejectElements="japaneseTag"
  merge="true"/>

<elementProposals
  path="/*[@xml:lang!='he']//*"
  rejectElements="hebrewTag"
  merge="true"
/>
```

Attributes:

To control the **attributes** that are proposed for an element, you can use the following attributes for the `<elementProposals>` element:

- **path** - A path within the document that matches the element that will have its attribute proposals changed. For example, `"title"` matches all the `<title>` elements in the document, while `"chapter/title"` matches only the `<title>` elements that are direct children of the `<chapter>` element. You can use simplified forms of XPath in this attribute. For examples of such forms of XPath expressions, see the note in XML Preferences *(on page 215)*.

> **Note:**
>
> If this attribute is missing, the customization will apply to the proposals for all elements. You can intentionally omit this attribute and use *possibleAttributes (on page 2316)* or *rejectAttributes (on page 2316)* to specify or restrict attributes for an entire *framework*.
>
> For example, suppose that you only want to allow a limited set of attributes in a customized *framework*. The configuration file should look like this:
>
> ```
> <elementProposals possibleAttributes="
>              id domains href scope format type conref
>              props keyref class"/>
> ```
>
> Since the `@path` attribute is missing, this applies to the entire *framework* and only the specified attributes will be proposed.

- **insertAttributes** - A space-separated sequence of attribute names that will be inserted along with the element.

```
<elementProposals path="ol/li" insertAttributes="product platform"/>
```

- **insertAttribute** - This is similar to the preceding attribute, but this one also allows you to specify a value for the attribute that will be inserted. This attribute should be used like this:

```
<elementProposals path="ol/li">
    <insertAttribute name="platform" value="test"/>
</elementProposals>
```

- **possibleAttributes** - A space-separated list of attribute names that will be shown in the content completion list when invoked inside an element that is specified in the `@path` attribute.

  When using this attribute to specify multiple attributes, only use one entry with the attribute names separated by a space:

```
<elementProposals possibleAttributes="scope format type"/>
```

- **rejectAttributes** - A space-separated list of attribute names that will be filtered out from the list of proposals that are presented in the content completion list. Each time the element specified in the `@path` attribute is inserted into the document, the list of proposals in the *Content Completion Assistant* will include the entries that are defined in the associated schema, minus the attributes specified in this attribute.

  When using this attribute to specify multiple attributes, only use one entry with the attribute names separated by a space:

```
<elementProposals rejectAttributes="importance platform product"/>
```

Other Important Notes About the Configuration File

Important:

- By default, the element names that do not have a namespace prefix are considered from *no-namespace*. Consider declaring the namespace mapping on the root of the configuration file and prefixing the element names from the `@elementPath` and `@model` attributes.
- This configuration file only affects the content completion assistance. It has no effect on validation or operations invoked from other areas in the interface (such as the toolbar or menus).
- To test the effects of your changes, you should restart the application, although in some cases, you can simply use the **Reload (F5)** action to test your customizations.
- When an XML element from the document is matched against a list of configured `elementProposals`, the first one in sequence takes precedence. Therefore, make sure you place the more specific `elementProposals` (those with a longer path) first in your configuration file.
- Simple wildcard patterns can be used in the following attributes: `@possibleElements`, `@rejectElements`, `@possibleAttributes`, and `@rejectAttributes`. For example, `code*`, `*block`, `con*ref`, `_*`.
- Editor variables *(on page 332)* can be used in the `@value` attribute of the `<insertAttribute>` element. For example:

```
<elementProposals path="prolog/critdates/created">
    <insertAttribute name="date" value="${date(yyyy-MM-dd)}"/>
</elementProposals>
```

- Only simple recursion cases are detected and avoided by the editor, and logged to the console. Therefore, if complex `elementProposals` patterns are defined, you should avoid *infinite recursions*.

Examples: Configuring the Element Proposals

- **Example 1: Automatically Insert Elements**

  Suppose that you want to automatically insert a paragraph element (`<p>`) whenever a DITA ordered list item element (`<ol/li>`) is inserted, and also to not allow any other element besides a paragraph inside the ordered list items.

  To achieve this, the configuration file should include the following:

  ```
  <elementProposals path="ol/li" insertElements="p"
        possibleElements="_INSERTED_"/>
  ```

  Tip:
  This particular example modifies an action that inserts a list in a DITA document. There are several ways to invoke this action in the interface. For example, there is a toolbar button and an action in the **DITA** menu that inserts a list. However, since the configuration file only affects the *Content Completion Assistant*, this modification will have no effect on the behavior of the toolbar or menu action. Those actions would need to be configured separately if you want the result to be the same as the content completion proposal. For more information, see Customizing the Author Mode Editing Experience for a Framework *(on page 2262)*.

- **Example 2: Insert Complex Element Structure**

  For a more complex example, suppose that you want to insert a complex structure whenever a DITA `<prolog>` element is inserted.

  For instance, if you want to insert the following structure inside `<prolog>` elements:

  ```
  <prolog>
    <author></author>
    <metadata>
        <keywords>
            <keyword></keyword>
            <keyword></keyword>
        </keywords>
  ```

```
      </metadata>
    </prolog>
```

the configuration file should include the following:

```
    <elementProposals path="prolog" insertElements="author metadata"/>
    <elementProposals path="prolog/metadata" insertElements="keywords"/>
    <elementProposals path="prolog/metadata/keywords"
           insertElements="keyword, keyword"/>
```

- **Example 3: Limit Possible Elements**

  Suppose that you also want to limit the proposals for the `<keywords>` element to only allow the user to insert `<audience>` or `<keyword>` elements. The configuration file should include the following:

  ```
  <elementProposals path="prolog/metadata" insertElements="keywords"
             possibleElements="audience keywords"/>
  ```

  Suppose that you want to simply restrict your users from inserting `<image>` elements inside DITA list item elements (`<li>`), but still propose all the other elements that are defined in the associated schema. The configuration file should look like this:

  ```
  <elementProposals path="li" rejectElements="image" />
  ```

Examples: Configuring the Attributes Proposals

- **Example 1: Automatically Insert Attributes**

  Suppose that you want to insert an `@id` attribute (with an empty value) whenever a DITA list item element (`<li>`) is inserted. The configuration file should include the following:

  ```
  <elementProposals path="li" insertAttributes="id"/>
  ```

- **Example 2: Limit Possible Attributes**

  Suppose that you also want to limit the number of choices for attributes that are presented to the user whenever a DITA list item element (`<li>`) is inserted. The configuration file should look like this:

  ```
  <elementProposals path="li" insertAttributes="id"
            possibleAttributes="id product platform audience"/>
  ```

  Suppose that you want to simply restrict your users from inserting `@conref` attributes inside DITA topics (`<topic>` element), but still propose all the other attributes that are defined in the associated schema. The configuration file should look like this:

  ```
  <elementProposals path="topic" rejectAttributes="conref" />
  ```

Configuring the Proposals for Attribute and Element Values *(on page 2319)*
Customizing the Rendering of Elements *(on page 2325)*

Configuring the Proposals for Attribute and Element Values

Oxygen XML Editor includes support for configuring the proposed values that appear in the *Content Completion Assistant (on page 3418)*. To do so, a configuration file is used, along with the associated schema, to add or replace possible values for attributes or elements that are proposed in the *Content Completion Assistant*.

For an example of a specific use-case, suppose that you want the *Content Completion Assistant* to propose several possible values for the language code when you use an `@xml:lang` attribute.

Setting up the Content Completion Configuration File

To customize the configuration file for the *Content Completion Assistant (on page 3418)*, follow these steps:

1. Create a new `resources` folder (if it does not already exist) in the `frameworks` directory for the particular document type (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources`).
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association**. Select the particular document type, click the **Edit** button, and in the **Classpath** tab *(on page 152)* add a link to that `resources` folder (if it does not already exist).
3. Create a new configuration file or edit an existing one.
    a. To easily create a new configuration file, you can use the *Content Completion Configuration* document template that is included in Oxygen XML Editor (**File > New > Framework templates > Oxygen Extensions > Content Completion Configuration**). The document template includes details about how each element and attribute is used in the configuration file.
    b. If a configuration file (`cc_config.xml`) already exists for the particular document type (in the `resources` folder), you can modify this existing file.

    c. If you extend a framework, you need to copy the content of the `cc_config.xml` file from the base framework and modify it (e.g. create a `resources` folder in your framework extension folder and place the file there). You also need to make sure that the folder that contains the `cc_config.xml` file in your extension (e.g. `resources`) is listed in the **Classpath** tab *(on page 152)* before the one from the base framework.

    If you only want to make small changes or add extra rules in your custom content completion configuration file, you need to name it `cc_config_ext.xml` and all the rules inside it are merged with the base `cc_config.xml` file. The merging is done by taking all the rules specified in the `cc_config_ext.xml` file into consideration after processing the set of rules from the base `cc_config.xml` file.
4. Make the appropriate changes to your custom configuration file.

5. Save the file in the `resources` folder for the particular document type, using the fixed name: `cc_config.xml` (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/cc_config.xml`).
6. Restart the application and open an XML document. In the *Content Completion Assistant* you should see your customizations.

> **Tip:**
> In some cases, you can simply use the **Refresh (F5)** action to test your customizations, without having to restart the application.

> **Attention:**
> In the **Classpath** tab *(on page 152)*, if you have references to multiple `resources` folders, each with its own `cc_config.xml` file, the first reference listed in the **Classpath** tab takes precedence and the multiple configuration files are not combined.

Configuring Proposed Values

For the purposes of adding or replacing the values that are proposed, the configuration file (`cc_config.xml`) includes a series of `valueProposals` instructions that will match an element or attribute name and has the following attributes:

- **path** - A path within the document that matches the element or attribute that will have its content completion proposals changed. For example:
  - `path="title"` matches all the `<title>` elements in the document.
  - `path="chapter/title"` matches only the `<title>` elements that are direct children of the `<chapter>` element.
  - `path="@xml:lang"` matches all the `@xml:lang` attributes in the document.
  - `path="title/@xml:lang"` matches only the `@xml:lang` attributes that appear on `<title>` elements.

  You can use simplified forms of XPath in this attribute.

  The XPath expressions can accept multiple attribute conditions and inside each condition you can use *AND/OR* boolean operators and parentheses to override the priority.

  You can use one or more of the following attribute conditions (default attribute values are not taken into account):
  - *element[@attr]* - Matches all instances of the specified element that include the specified attribute.
  - *element[not(@attr)]* - Matches all instances of the specified element that do not include the specified attribute.
  - *element[@attr = "value"]* - Matches all instances of the specified element that include the specified attribute with the given value.
  - *element[@attr != "value"]* - Matches all instances of the specified element that include the specified attribute and its value is different than the one given.

Example: The following are examples of how you could use multiple boolean operators and parentheses inside an attribute condition:

```
*[@a and @b or @c and @d]
*[@a and (@b or @c) and @d]
```

The following are just examples of how simplified XPath expressions might look like:

- *elementName*
- *//elementName*
- */elementName1/elementName2/elementName3*
- *//xs:localName*
- *//xs:documentation[@lang="en"]*

Note:
Using a namespace prefix requires that you declare it on the `<elementProposals>` element or on an ancestor element. For example:

```
<elementProposals xmlns:db5="http://docbook.org/ns/docbook"
  path="db5:listitem" insertElements="db5:para" />
```

- **editable** - Specifies the editable state of the attribute values, as reflected in the **Attributes** view *(on page 638)* and the **In-place Attributes Editor** *(on page 640)*. The possible values for the `@editable` attribute are:
  - **true** - The attribute values can be edited by choosing from a combo box or manually providing a value.
  - **false** - The attribute values cannot be edited.
  - **onlyAllowedItems** - The attribute values can be edited, but only by choosing from a list of proposed values, in a non-editable combo box.

The new value proposals are specified in the `<valueProposals>` element through:

- One or more `<item>` elements, which are grouped inside an `<items>` element.

Tip:
The `<item>` element can have a `@listValue` attribute, which can be set to **true** if you want those items to be part of a list attribute value (such as `attr="item1 item2"`).

- An `<xslt>` element that references an XSLT script that gets executed and must return an `<items>` element.

The behavior of the `<items>` or `<xslt>` elements are specified with the help of the `@action` attribute, which can have any of the following values:

- **append** - Adds new values to appear in the proposals list (default value).
- **addIfEmpty** - Adds new values to the proposals list only if no other values are contributed by the schema.
- **replace** - Replaces the values contributed by the schema with new values to appear in the proposals list.

The values in the configuration file can be specified either directly or by calling an external XSLT file that will extract data from an external source. An `<xslt>` element must be used in this situation.

Note:

`valueProposals` offers more flexibility compared to the old `match` element that was marked as deprecated.

```
<match elementName="lg" elementNS="http://www.oxygenxml.com/ns/samples">
    <items action="replace">
        <item value="stanza"/>
        <item value="refrain"/>
    </items>
</match>
```

Other Important Notes About the Configuration File

Important:

- This configuration file only affects the content completion assistance, not validation.
- To test the effects of your changes, you should Refresh the source document *(on page 766)*.

Example: Specifying Values Directly

If you want to specify the values directly, the configuration file should look like this:

```
<!-- Replaces the values for an element with the local name "lg",
      from the given namespace -->
<valueProposals path="x:lg" xmlns:x="http://www.oxygenxml.com/ns/samples">
  <items action="replace">
    <item value="stanza"/>
    <item value="refrain"/>
  </items>
</valueProposals>

<!-- Adds two values for an attribute "type", from no namespace -->
<valueProposals path="@type" editable="onlyAllowedItems">
    <items>
```

```
        <item value="stanza"/>
        <item value="refrain"/>
    </items>
</valueProposals>
```

Example: Using Attribute Conditions

The possible values of an attribute depend on the value of another attribute from the same element:

```
<valueProposals path="property[@name='color']">
  <items>
    <item value="red"/>
    <item value="blue"/>
  </items>
</valueProposals>

<valueProposals path="property[@name='shape']">
  <items>
    <item value="rectangle"/>
    <item value="square"/>
  </items>
</valueProposals>
```

Example: Calling an External XSLT Script

If you want to collect values from an external XSLT script, the configuration file should include something like this:

```
<xslt href="../xsl/get_values_from_db.xsl" useCache="false" action="replace"/>
```

In this example, the `get_values_from_db.xsl` is executed to extract values from a database.

Tip:
You can use `xsl:message` as a debugging mechanism. These messages are presented in the results area at the bottom of the application whenever the *Content Completion Assistant* is invoked.

Note:
A comprehensive XSLT sample is included in the **Content Completion Configuration** document template (in the **Framework Templates > Oxygen Extensions** section of the **New** document wizard *(on page 377)*).

Note:
If `@useCache` is set to *false*, then the XSLT will be invoked any time the proposals are needed. If `@useCache` is set to *true*, then the XSLT is executed once and the obtained proposals are kept in a cache and returned every time the proposals are requested again. You can use the **Validate** action to drop the cached values and recompute them.

Configuring Proposed Values in the Context Where the Content Completion was Invoked

Web Author Customization Note:
This particular scenario is not supported for an Oxygen XML Web Author customization.

A more complex scenario is if you want to choose the possible values to propose, depending on the context of the element where the content completion was invoked.

Suppose that you want to propose certain possible values for one property (for example, *color*) and other values for another property (for example, *shape*). If the property represents a color, then the values should represent applicable colors, while if the property represents a shape, then the values should represent applicable shapes. See the following code snippets:

Your main document:

```
<sampleArticle>
  <!-- The possible values for @value should be "red" and "blue" -->
  <property name="color" value=""/>
  <!-- The possible values for @value should be "square" and "rectangle" -->
  <property name="shape" value=""/>
</sampleArticle>
```

The content completion configuration file:

```
<config xmlns="http://www.oxygenxml.com/ns/ccfilter/config">
    <valueProposals path="property/@value">
      <xslt href="get_values.xsl" useCache="false" action="replace"/>
    </valueProposals>
</config>
```

The stylesheet that defines the possible values based on the context of the property on which the content completion was invoked:

```
<xsl:stylesheet
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  exclude-result-prefixes="xs"
  version="3.0">

  <xsl:param name="documentSystemID" as="xs:string"></xsl:param>
```

```
  <xsl:param name="contextElementXPathExpression" as="xs:string"></xsl:param>

  <xsl:template name="start">
    <xsl:apply-templates select="doc($documentSystemID)"/>
  </xsl:template>

  <xsl:template match="/">
   <xsl:variable name="propertyElement" as="element()">
     <xsl:evaluate xpath="$contextElementXPathExpression" context-item="./*"/>
   </xsl:variable>

   <items>
     <xsl:if test="$propertyElement/@name = 'color'">
       <item value='red'/>
       <item value='blue'/>
     </xsl:if>
     <xsl:if test="$propertyElement/@name = 'shape'">
       <item value='rectangle'/>
       <item value='square'/>
     </xsl:if>
   </items>
  </xsl:template>
</xsl:stylesheet>
```

The `contextElementXPathExpression` parameter will be bound to an XPath expression that identifies the element in the context where the content completion was invoked.

Related information

Configuring the Proposals for Elements and Attributes *(on page 2310)*
Customizing the Rendering of Elements *(on page 2325)*

Customizing the Rendering of Elements

In addition to the support for configuring the proposals that appear in the *Content Completion Assistant (on page 3418)*, Oxygen XML Editor also includes support for customizing how the elements are rendered. You can do this by using the *XMLNodeRendererCustomizer* API extension *(on page 2387)*, but you can also use the same configuration file that is used to configure the content completion proposals.

For an example of a specific use-case, suppose that in DITA you want the names of paragraph elements (`<p>`) to be rendered as "**Paragraph**" instead of "**p**" in the various components in **Author** mode (such as in the **Outline** view *(on page 549)*, **Elements** view *(on page 643)*, **Attributes** view *(on page 638)*, and the breadcrumb navigation bar). To achieve this, you can use the `<elementRenderings>` element in the configuration file.

Setting up the Content Completion Configuration File

To customize the configuration file for the *Content Completion Assistant (on page 3418)*, follow these steps:

1. Create a new `resources` folder (if it does not already exist) in the `frameworks` directory for the particular document type (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources`).
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association**. Select the particular document type, click the **Edit** button, and in the **Classpath** tab *(on page 152)* add a link to that `resources` folder (if it does not already exist).
3. Create a new configuration file or edit an existing one.
    a. To easily create a new configuration file, you can use the *Content Completion Configuration* document template that is included in Oxygen XML Editor (**File > New > Framework templates > Oxygen Extensions > Content Completion Configuration**). The document template includes details about how each element and attribute is used in the configuration file.
    b. If a configuration file (`cc_config.xml`) already exists for the particular document type (in the `resources` folder), you can modify this existing file.

    c. If you extend a framework, you need to copy the content of the `cc_config.xml` file from the base framework and modify it (e.g. create a `resources` folder in your framework extension folder and place the file there). You also need to make sure that the folder that contains the `cc_config.xml` file in your extension (e.g. `resources`) is listed in the **Classpath** tab *(on page 152)* before the one from the base framework.

    If you only want to make small changes or add extra rules in your custom content completion configuration file, you need to name it `cc_config_ext.xml` and all the rules inside it are merged with the base `cc_config.xml` file. The merging is done by taking all the rules specified in the `cc_config_ext.xml` file into consideration after processing the set of rules from the base `cc_config.xml` file.
4. Make the appropriate changes to your custom configuration file.
5. Save the file in the `resources` folder for the particular document type, using the fixed name: `cc_config.xml` (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/cc_config.xml`).
6. Restart the application and open an XML document. In the *Content Completion Assistant* you should see your customizations.

Tip:

In some cases, you can simply use the **Refresh (F5)** action to test your customizations, without having to restart the application.

Attention:

In the **Classpath** tab *(on page 152)*, if you have references to multiple `resources` folders, each with its own `cc_config.xml` file, the first reference listed in the **Classpath** tab takes precedence and the multiple configuration files are not combined.

Changing the Rendering of Elements (Their Names, Annotations, and Icons)

For the purposes of customizing how the content completion elements are rendered, you can use the `<render>` element inside a `<elementRenderings>` element to specify how element names, their annotations, and their icons are rendered.

The `<elementRenderings>` element supports the `@platform` attribute, which can have one of the following values:

webapp

The element renderings are only applied to Oxygen XML Web Author.

standalone

The element renderings are only applied to standalone distributions of **Oxygen**.

eclipse

The element renderings are only applied to Eclipse plugin distributions of **Oxygen**.

Note:

If the `@platform` attribute is missing, the element renderings are applied to all types of distributions.

You can use the following attributes for the `<render>` element:

element

Identifies the element to be customized, in the form of a qualified name. If it does not have a prefix, it is considered to be from *noNamespace*.

as

Provides the name (label) that will be displayed for the element in various components in **Author** mode (the *Content Completion Assistant*, the breadcrumb navigation bar, the **Full Tags** display mode *(on page 604)*, and the **Outline** *(on page 549)*, **Elements** *(on page 643)*, and **Attributes** *(on page 638)* views). This attribute is optional. If it is missing, the name of the element is used.

If you want to translate this label into another language, use the `${i18n(key_name)}` editor variable *(on page 340)*. The following code snippet shows how the DITA paragraph elements (`<p>`) can be translated:

```
<elementRenderings>
    <render element="p" as="${i18n(cc_p)}"/>
</elementRenderings>
```

Note:
The `cc_p` id is a key that identifies the translations available for the paragraph element.

iconPath

Optional attribute that specifies the icon for the element. This is shown in the *Content Completion Assistant* and the **Outline** view *(on page 549)* in **Author** mode. If it is a relative path, the full path of the icon image file will be computed starting from the directory of the configuration file (for example, a value of `"myImg.png"` will cause Oxygen XML Editor to load `"frameworks/$ {framework}/resources/myImg.png"`). If you want to access a built-in resource, the value can begin with a forward slash `"/"`, and the image file will be searched for in the Oxygen XML Editor classpath resources (for example,`"/images/OrderedList16.png"` will load an icon from the built-in Oxygen XML Editor *JAR* file resources.

xml:lang (Deprecated)

It is recommended to use the `${i18n(key_name)}` editor variable *(on page 340)* instead. Optional attribute that could be used to render the same element differently, depending on the language. If there are multiple `<render>` elements for the same `@element` attribute (element name) and the `@xml:lang` attribute is missing on one of them, that one will be considered the default fallback value to be used if none of the others match the language specified in the interface.

Note:
The default entry should be listed first, since the application tries to match them in sequence and the last match found is the one that is used.

For example, suppose that you want the name of DITA paragraph elements (`<p>`) to be rendered as "Paragraphe" if the language is French, "Absatz" if the language is German, and "Paragraph" if the language is English (or any other language). Your configuration file should look something like this:

```
<elementRenderings>
    <render element="p" as="Paragraph"/>
    <render element="p" as="Paragraphe" xml:lang="fr"/>
    <render element="p" as="Absatz" xml:lang="de"/>
</elementRenderings>
```

You can also use the configuration file to customize the annotations for elements. For this purpose, the `<render>` element also accepts the following element to change the tooltip annotations for an element (in both **Author** mode and **Text** mode):

annotation

This element can be used within the `<render>` element to customize the tooltip annotations that are displayed for the element in various components in **Author** mode (such as tooltips shown in the *Content Completion Assistant* documentation window, the breadcrumb navigation bar, the **Full Tags** display mode *(on page 604)*, and the **Outline** *(on page 549)*, **Elements** *(on page 643)*, **Attributes** *(on page 638)* views), as well as the tooltips that are displayed when you hover over elements in **Text** mode. You can use HTML content to style the annotations (see the example below *(on page 2330)*).

Note:
If this element is missing, the styling for the annotations for that element is collected from the associated schema *(on page 629)*.

Tip:
The annotations can also be translated in the configuration file. For example:

```
<elementRenderings>
    <render element="p" as="${i18n(cc_p)}">
        <annotation>${i18n(cc_p)}</annotation>
    </render>
</elementRenderings>
```

Other Important Notes About the Configuration File for Rendering Elements

Important:

- This configuration file only affects the content completion assistance, not validation.
- To test the effects of your changes, you should restart the application, although in some cases, you can simply use the **Reload (F5)** action to test your customizations.
- If the *framework (on page 3420)* has an associated *style guide*, then the annotations defined in the configuration file will take precedence over those defined in the *style guide*. To check to see if your *framework* uses a *style guide*, look for the following folder: `${oXygenInstallDir}frameworks/${framework}/styleguide/`. If that folder exists, it is recommended that you make your annotation changes directly in the *style guide*, rather than in the configuration file.
- If an *XMLNodeRendererCustomizer* API extension *(on page 2387)* has been implemented for the *framework* and a configuration file is also used, the rendering customization for an element will be the result of merging the two. For example, if the *XMLNodeRendererCustomizer*

implementation customizes the element name, while the configuration file specifies an icon for the element, the properties of both customizations will be rendered. However, if both implementations define the same property (for example, both specify the rendering of an element name), the customizations defined in the configuration file take precedence.
- The rendering customizations defined in the configuration file also apply to aspects of the Oxygen XML Web Author interface.

Example: Changing the Rendering of an Element

Suppose that you want to render the name of the DITA `<title>` element to begin with a capital letter, use a custom icon for it, and provide specific documentation for that element in the various components in **Author** mode. The configuration file should look like this:

```
<elementRenderings>
   <render element="title"   as="Title"  iconPath="cimg/AcceptAll16.png">
      <annotation>
         <html xmlns="http://www.w3.org/1999/xhtml">
           <head>
             <title>Documentation for the Title Element</title>
           </head>
             <body>
           <p>A <i>heading</i> or <b>label</b> for the main parts of a topic</p>
             </body>
         </html>
             </annotation>
   </render>
</elementRenderings>
```

Configuring the Proposals for Attribute and Element Values *(on page 2319)*
Configuring the Proposals for Elements and Attributes *(on page 2310)*
Customizing XML Node Rendering *(on page 2387)*
Schema Annotations in Author Mode *(on page 629)*
Customizing Annotations in the Content Completion Assistant *(on page 2330)*

Customizing Annotations in the Content Completion Assistant

Oxygen XML Editor gathers documentation from the associated schemas (DTD, XML Schema, RelaxNG) and presents it for each element or attribute. For example, if you open the *Content Completion Assistant (on page 3418)* for a recognized XML vocabulary, documentation is displayed for each element provided by the associated schema. Similar information is displayed when you hover over tag names presented in the **Elements** view *(on page 643)*. If you hover over attributes in the **Attributes** view *(on page 638)* you also see information about each attribute, gathered from the same schema.

If you have a *framework* configuration *(on page 147)* set up for your XML vocabulary, there is a special XML configuration file that can be added to provide additional documentation information or links to additional information for certain elements and attributes.

To provide this additional information in the *Content Completion Assistant*, follow these steps:

1. Create a new folder in the configuration directory for the document type.

   Example: `OXYGEN_INSTALL_DIR/frameworks/dita/styleguide`

2. Use the **New** document wizard to create a file using the **Content Completion Styleguide** document template (in the **Framework Templates > Oxygen Extensions** section).
3. Save the file in the folder created in step 1, using the fixed name: `contentCompletionElementsMap.xml`.
4. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, and edit the document type configuration for your XML vocabulary. Now you need to indicate where Oxygen XML Editor will locate your mapping file by doing one of the following:
   - In the **Classpath** tab add a link to the newly created folder.
   - In the **Catalogs** tab add a new catalog file *(on page 838)*. The selected file needs to contain the following:

     ```
     <?xml version="1.0" encoding="UTF-8"?>
     <!DOCTYPE catalog PUBLIC "-//OASIS//DTD XML Catalogs V1.1//EN"
         "http://www.oasis-open.org/committees/entity/release/1.1/catalog.dtd">
     <catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
         <uri name="http://www.oxygenxml.com/{processed_dt_name}/styleguide/
     contentCompletionElementsMap.xml" uri="contentCompletionElementsMap.xml"/>
     </catalog>
     ```

     where *{processed_dt_name}* is the name of the document type in lower case and with spaces replaced by underscores.

     > **Note:**
     > If Oxygen XML Editor finds a mapping file in both locations, the one in the **Catalogs** tab takes precedence.

5. Make the appropriate changes to your custom mapping file.

   Example: You can look at how the DITA mapping file is configured: `OXYGEN_INSTALL_DIR/frameworks/dita/styleguide/contentCompletionElementsMap.xml`

   The associated XML Schema contains additional details about how each element and attribute is used in the mapping file.

6. Re-open the application and open an XML document.

In the *Content Completion Assistant (on page 3418)*, you should see the additional annotations for each element.

Translating Annotations

Annotations in the Content Completion Assistant can be displayed in various languages. Based on the language set for the interface, Oxygen XML Editor looks for several filename formats to determine the information to load for the content completion annotations. These files that begin with the name *contentCompletionElementsMap*, are located in the `styleguide` folder for each built-in framework (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/styleguide`).

For example, for English, the files are loaded in the following order (from specific to more general):

- `contentCompletionElementsMap_en_US.xml` or `contentCompletionElementMap_en_UK.xml`, and so on
- `contentCompletionElementsMap_en.xml`
- `contentCompletionElementsMap.xml`

If you want the annotations to be displayed in another language, you need to create similar files for the particular language. For example, to show annotations in German, create a file with one of the following names (and store it in the `styleguide` folder for your framework):

- `contentCompletionElementsMap_de_DE.xml`
- `contentCompletionElementsMap_de.xml`

Related Information:
Customizing the Rendering of Elements *(on page 2325)*

Customizing the Content Completion Assistant for Author Mode Only

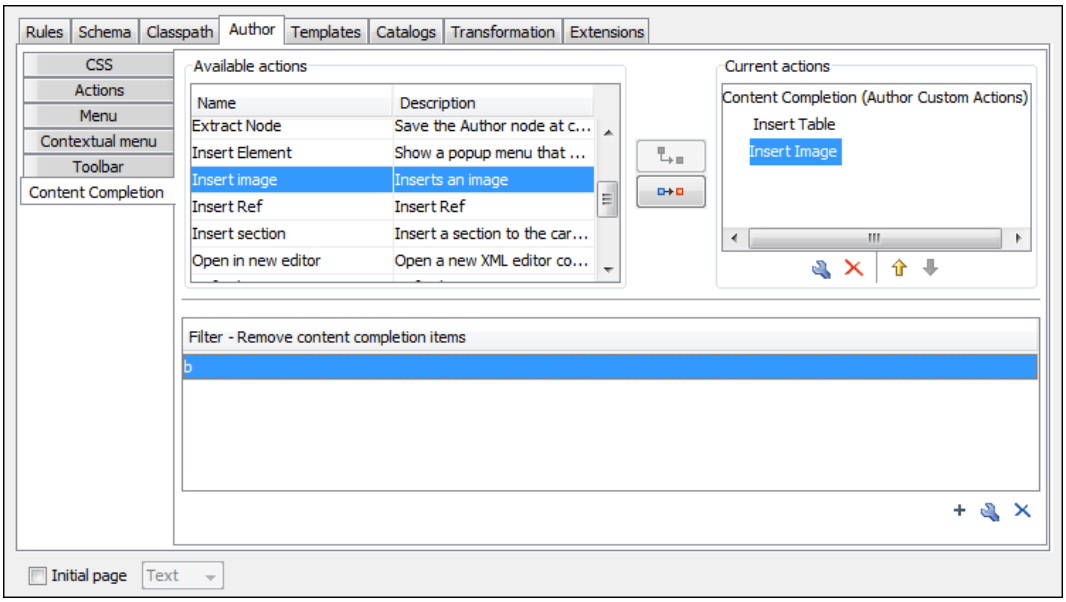
You can customize the content of the following **Author** controls, adding items (which, when invoked, perform custom actions) or filtering the default contributed ones:

- *Content Completion Assistant (on page 3418)* window
- **Elements** view *(on page 643)*
- **Insert Element** menus (from the **Outline** view *(on page 549)* or breadcrumb *(on page 612)* contextual menus)

You can use the content completion customization support in a custom *framework (on page 3420)* by following this procedure:

1. Open the **Document type** configuration dialog box *(on page 147)* for your custom *framework* and select the **Author** tab. Next, go to the **Content Completion** tab *(on page 167)*.

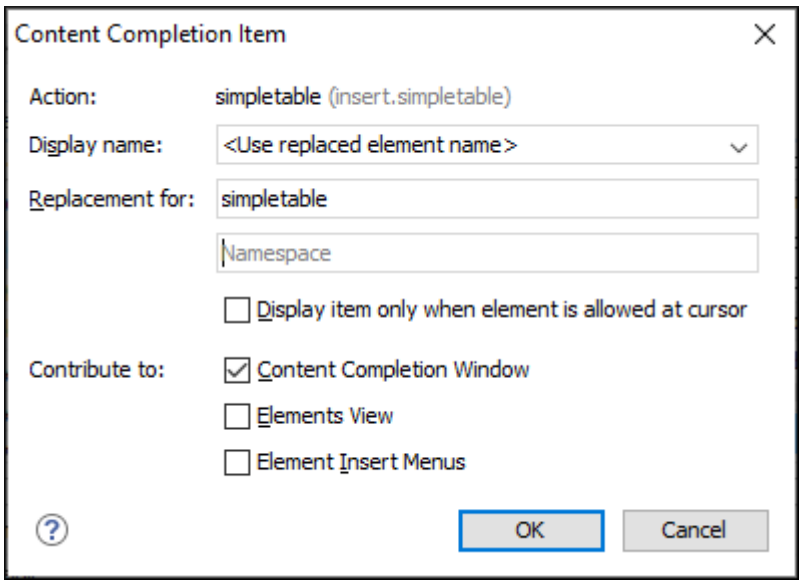
Figure 594. Customize Content Completion



The top side of the **Content Completion** section contains the list with all the actions defined within the custom *framework* and the list of actions that you decided to include in the *Content Completion Assistant* list of proposals. The bottom side contains the list with all the items that you decided to remove from the *Content Completion Assistant* list of proposals.

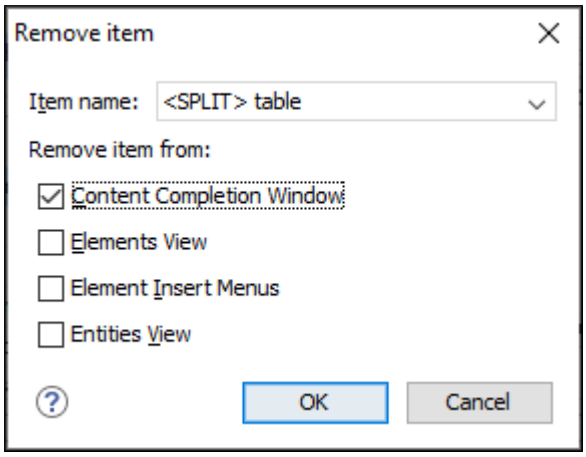
2. If you want to add a custom action to the list of current **Content Completion** proposals, select the action item from the **Available actions** list and click the **Add as child** or **Add as sibling** button to include it in the **Current actions** list. A **Content Completion Item** dialog box appears, giving you the possibility to select where to provide the selected action.

Figure 595. Content Completion Item Dialog Box



3. If you want to exclude a certain item from the **Content Completion** proposals, you can use the **Add** button from the **Filter - Remove content completion items** list. The **Remove item** dialog box is displayed, allowing you to input the item name and to choose the controls that filter it. The **Item name** combo box accepts wildcards.

Figure 596. Remove Item Dialog Box



Note:
In the **Item name** drop-down menu, **<SPLIT>** refers to the action of splitting the element and creating a new one, while **<ENTER>** refers to the action of inserting a new line.

Customizing the Content Completion Assistant Using a Configuration File *(on page 2309)*

Configuring Transformation Scenarios for a Framework

When distributing a *framework (on page 3420)* to users, it is a good idea to have the transformation scenarios already configured. This helps the content authors publish their work in various formats. By being contained in the *framework* configuration, the scenarios can be distributed along with the actions, menus, toolbars, and catalogs.

To create a transformation scenario for your *framework*, follow these steps:

1. Create an `xsl` folder inside your custom *framework* directory (*`[OXYGEN_INSTALL_DIR]`*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).

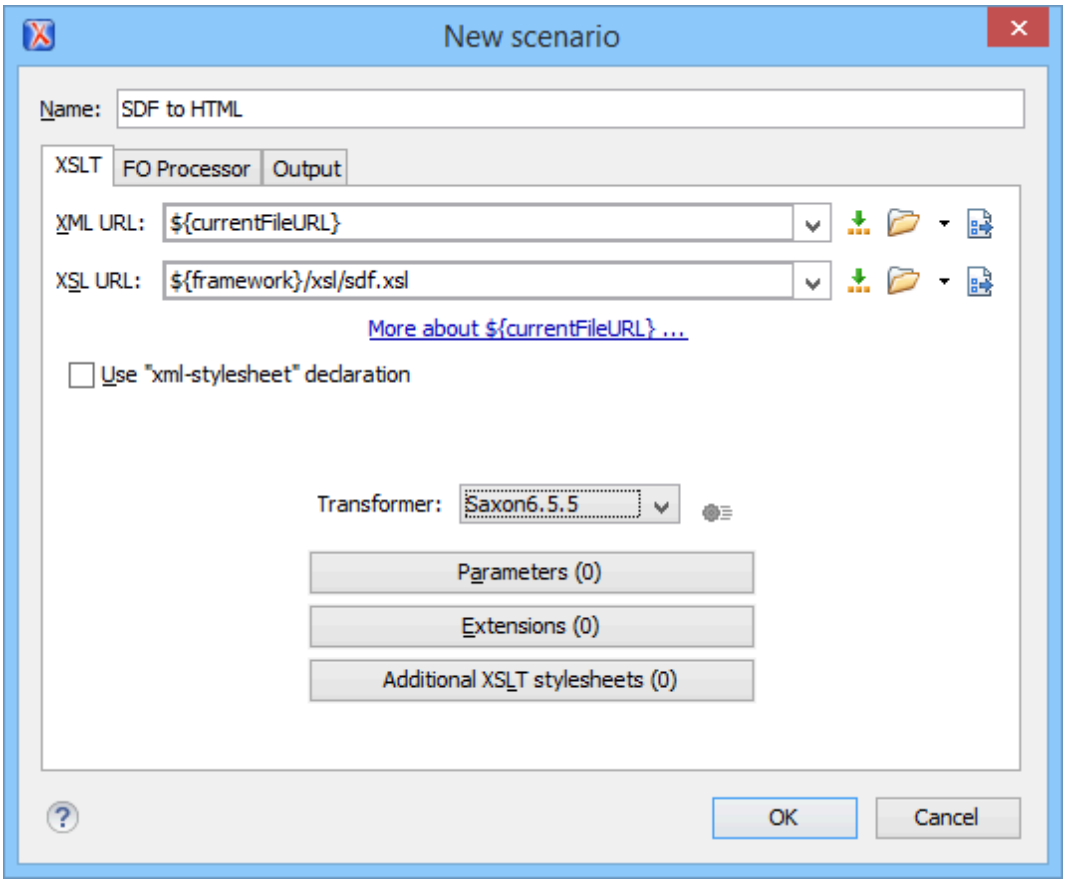
   The folder structure for the documentation *framework* should be:

```
oxygen
  frameworks
     [CUSTOM_FRAMEWORK_DIR]
       schema
       css
```

```
templates
xsl
```

2. Create an `xsl` file and save it in the `xsl` folder. To help you get started, you can use the sample `sdf.xsl` file found in the sample framework customization package.
3. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Associations**. Select the particular *framework*, click the **Edit** button to open **Document Type Configuration dialog box** *(on page 147)*, and choose the **Transformation** tab. Click the **New** button and choose the appropriate type of transformation (for example, **XML transformation with XSLT**).
   In the **New scenario** dialog box, fill in the following fields:
   - Fill in the **Name** field with the name of your transformation scenario.
   - Set the **XSL URL** field to path of your custom stylesheet (for example, `${framework}/xsl/mycustom.xsl`).

Figure 597. Configuring a New XSLT Transformation Scenario



4. Change to the **Output** tab. Configure the fields as follows:
   - Set the **Save as** field to `${cfd}/${cfn}.html`. This means the transformation output file will have the name of the XML file and the *html* extension and will be stored in the same folder.
   - Select the **Open in Browser/System Application** option.

> **Note:**
> To set the browser or system application that will be used, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Global**, and set it in the **Default**

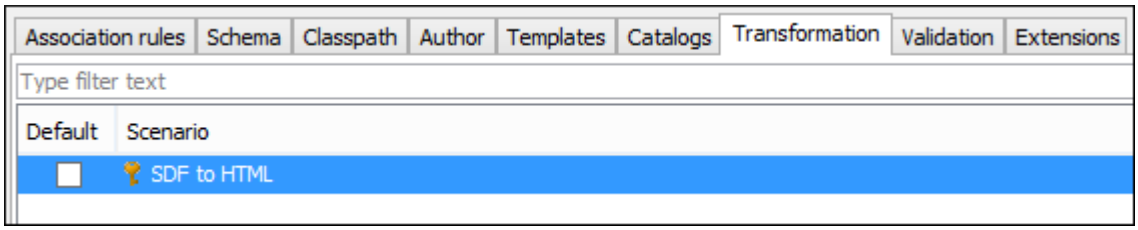
Internet browser field. This will take precedence over the default system application settings.

- Select the **Saved file** option.

5. Click the **OK** button to save the new scenario.

Now the scenario is listed in the **Transformation** tab:

Figure 598. Transformation Tab



To test the transformation scenario that you just created, you can use the sample `sdf.xml` file found in the sample framework customization package. Click the **Apply Transformation Scenario(s)** button to display the **Transform with** dialog box. The scenario list contains the scenario you defined earlier. Select the *SDF to HTML* scenario that you just defined and click the **Apply associated** button. The HTML file is saved in the same folder as the XML file and displayed in the browser.

Configuring Validation Scenarios for a Framework

You can distribute a *framework (on page 3420)* with a series of already configured validation scenarios. Also, this provides enhanced validation support that allows you to use multiple grammars to check the document. For example, you can use Schematron rules to impose guidelines that are otherwise impossible to enforce using conventional validation.

Note:
If a *main file* is associated with the current file, the validation scenarios defined in the *main file*, along with any Schematron schema defined in the default scenarios for that particular *framework*, are used for the validation. These take precedence over other types of validation units defined in the default scenarios for the particular *framework*. For more information on *main files*, see Contextual Project Operations Using 'Main Files' Support *(on page 428)* or Modular Contextual XML Editing Using 'Main Files' Support *(on page 841)*.

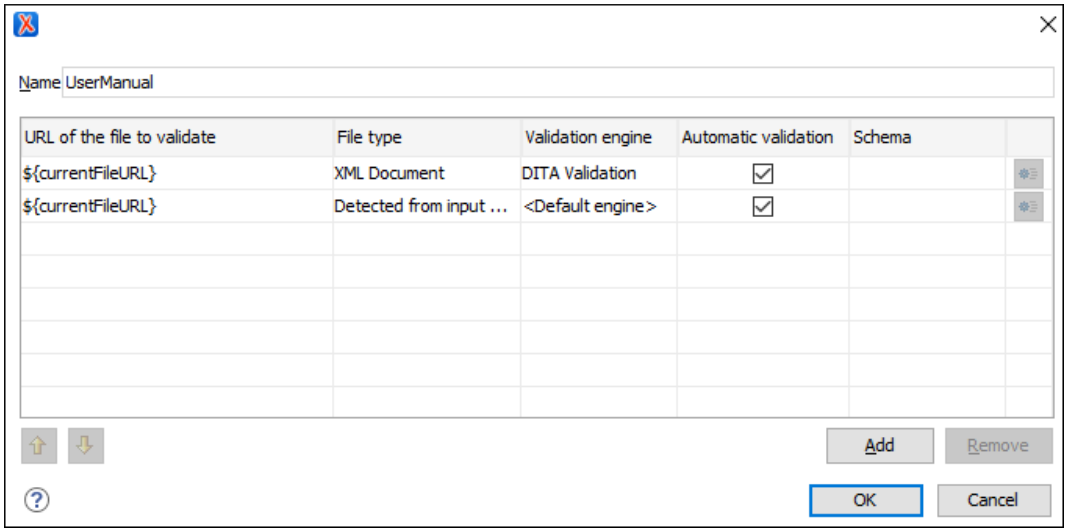
To associate a validation scenario with a specific *framework*, follow these steps:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association**.
2. Select the document type and click the **Edit** button to open the **Document Type Configuration** dialog box *(on page 147)*, then choose the **Validation** tab. This tab displays a list of document types. To set one or more of the validation scenarios listed in this tab to be used as the default validation scenario

(when another one is not specified in the validation process) for a specific document type, check the **Default** box for that specific document type.

3. To edit an existing scenario, select the scenario and click the **Edit** button. To add a new scenario, click the **New** button.
   In either case, a scenario configuration dialog box is displayed. It lists all the validation units for the scenario.

Figure 599. Validation Scenario Configuration Dialog Box



This scenario configuration dialog box allows you to configure the following information and options:

Name

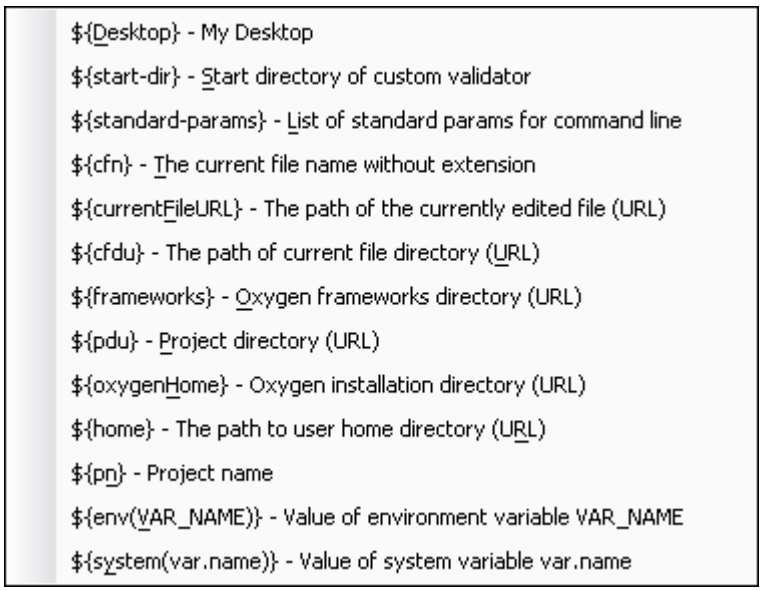
The name of the validation scenario.

URL of the file to validate

The URL of the main module that includes the current module. It is also the entry module of the validation process when the current one is validated. To edit the URL, double-click its cell and specify the URL of the main module by doing one of the following:

- Enter the URL in the text field or select it from the drop-down list.
- Use the **Browse** drop-down button to browse for a local, remote, or archived file.
- Use the **Insert Editor Variable** button to insert an editor variable *(on page 332)* or a custom editor variable *(on page 342)*.

Figure 600. Insert an Editor Variable



File type

The type of the document that is validated in the current validation unit. Oxygen XML Editor automatically selects the file type depending on the value of the **URL of the file to validate** field.

Validation engine

You can select one of the engines available in Oxygen XML Editor for validation of the particular document type:

- **Default engine** - The default engine is used to run the validation for the current document type, as specified in the preferences page for that type of document (for example, XSLT preferences page *(on page 254)*, XQuery preferences page *(on page 262)*, XML Schema preferences page *(on page 247)*).
- **DITA Validation** engine - Performs DITA-specific checks in the context of the specifications (it is similar to the process when using the **Validate and Check for Completeness** action *(on page 3118)* in the **DITA Maps Manager**, but for a local file rather than an entire *DITA map (on page 3419)*).
- **DITA Map Validation and Completeness Check** engine - Performs a validation process that checks the DITA map document and all referenced topics and maps (it is similar to the process when using the **Validate and Check for Completeness** action *(on page 3118)* in the **DITA Maps Manager**).
- **DITA-OT Project Validation and Completeness Check** engine - Performs a validation process that checks each context from the provided DITA-OT project file (it is similar to the process when using the **Validate and Check for Completeness** action *(on page 3118)* in the **DITA Maps Manager**).
- **Table Layout Validation** engine - Looks for table layout problems (for more information, see the Report table layout problems option *(on page 3123)*).

Automatic validation

If this option is selected, the validation operation defined by this row is also applied by the automatic validation feature *(on page 786)*. If the **Automatic validation** feature is disabled in the Document Checking preferences page *(on page 235)*, then this option is ignored, as the preference setting has a higher priority.

Schema

This option becomes active when you set the **File type** to **XML Document** and allows you to specify the schema used for the validation unit.

Settings

Depending on the selected validation engine, clicking the **Settings** button either opens the **Specify Schema** dialog box or the **Configure validation engine** dialog box.

- **Specify Schema Dialog Box**

  This dialog box allows you to specify a custom schema to be used for the validation process.

  Figure 601. Specify Schema Dialog Box

  
  The **Specify Schema** dialog box contains the following options:

  Use detected schema

  Uses the schema detected for the particular document *(on page 828)*.

  Use custom schema

  Allows you to specify the schema using the following options:

  - **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol *(on page 2563)*. You can specify the URL by

using the text field, the history drop-down, the **Insert Editor Variables** *(on page 332)* button, or the browsing actions in the **Browse** drop-down list.

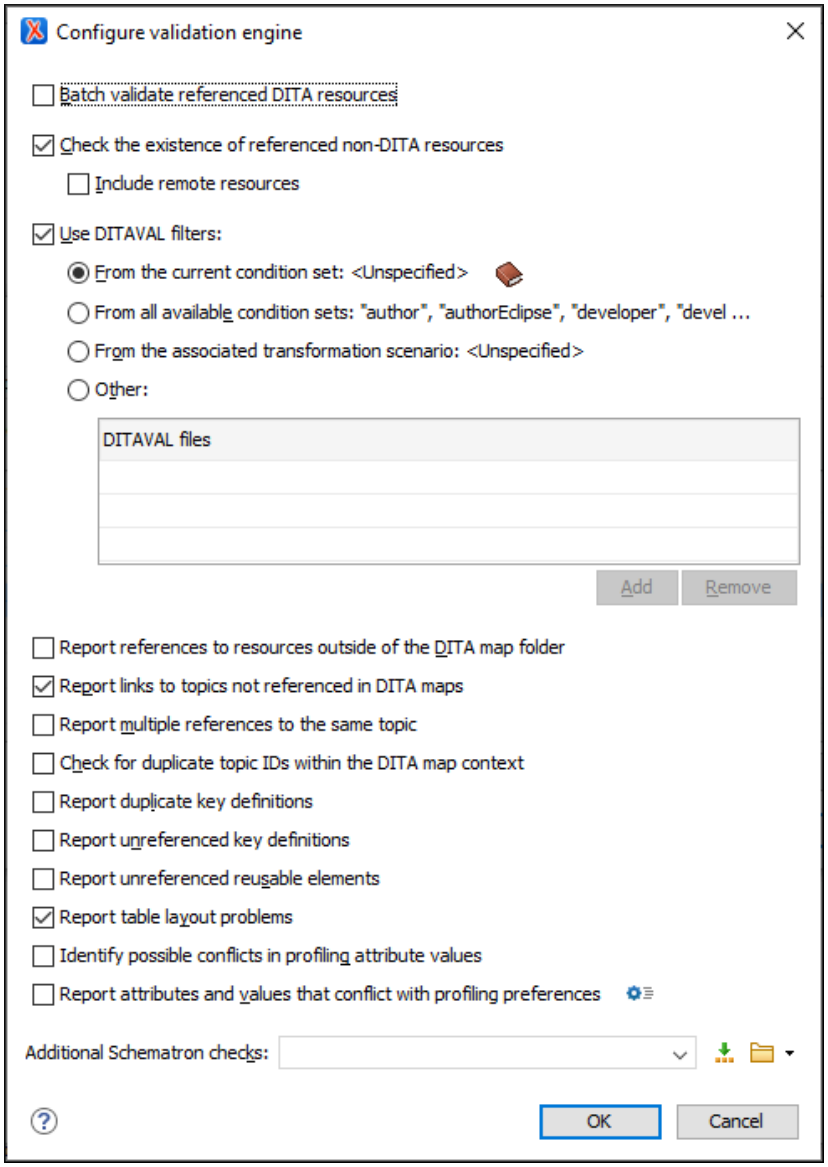
- **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the **URL** field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.
- **Embedded Schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.
- **Extensions**- Opens a dialog box that allows you to specify *Java extension JARs (on page 3420)* to be used during the validation.
- **Public ID** - Allows you to specify a public ID if you have selected a DTD.
- **Schematron phase** - If you select a Schematron schema, this drop-down list allows you to select a Schematron phase that you want to use for validation. The listed phases are defined in the Schematron document.

◦ **Configure Validation Engine Dialog Box**

This dialog box allows you to configure options for checking the DITA map document and all referenced topics and maps (similar to the process done when using the **Validate and Check for Completeness** action *(on page 3118)* in the **DITA Maps Manager**).

Note:
The options presented in the **Configure validation engine** dialog box depends on type of validation engine. For example, when configuring the **DITA-OT Project Validation and Completeness Check** validation engine, the dialog box has slightly fewer options (omitting those that are not applicable).

Figure 602. Example of the Configure Validation Engine Dialog Box



The **Configure Validation Engine** dialog box contains the following options:

Batch validate referenced DITA resources

This option specifies the level of validation that applies to referenced DITA files:

- If the checkbox is left unchecked (default setting), the DITA files will be validated using the rules defined in the DTD or XML Schema declared in the document.
- If the checkbox is selected, the DITA files will be validated using rules defined in their associated validation scenario *(on page 798)*.

Check the existence of non-DITA references resources

Extends the validation of referenced resources to non-DITA files.

Include remote resources

Select this option if you want to check that remote referenced binary resources (such as images, movie clips, ZIP archives) exist at the specified location.

Use DITAVAL filters

The content of the map is filtered by applying a profiling condition set before validation. You can choose between the following options:

- **From the current condition set** - The map is filtered using the condition set currently applied in the **DITA Maps Manager** view *(on page 3073)*. Clicking the **Details** icon opens a topic in the Oxygen XML Editor User Guide that explains how to create a profiling condition set.
- **From all available condition sets** - For each available condition set, the map content is filtered using that set before validation.
- **From the associated transformation scenario** - The filtering condition set is specified explicitly as a DITAVAL file in the current transformation scenario associated with the *DITA map*.
- **Other DITAVAL files** - For each DITAVAL file from this list, the map content is filtered using the DITAVAL file before validation. Use the **Add** or **Remove** buttons to configure the list. The **Add** button opens a dialog box that allows you to select a local or remote path to a DITAVAL file. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 332)* button, or the browsing actions in the **Browse** drop-down list.

Report references to resources outside of the DITA map folder

If selected, it will report any references to DITA resources that are located outside the *main DITA map (on page 3424)* folder.

Report links to topics not referenced in DITA maps

Checks that all the topics referenced by other topics are also linked in the *DITA map*. Also reports related links defined in relationship tables whose target topics are not referenced in the DITA Map.

Report multiple references to the same topic

If selected, it will report warnings when a topic is referenced multiple times in the *DITA map*, unless a unique `@copy-to` attribute is used on the `<topicref>` element for any topic that is referenced multiple times.

For example, it will **not** report a warning if there is a topic referenced twice, but the second `<topicref>` has a `@copy-to` attribute set:

```
<topicref href="topic.dita"/>
.....
 <topicref href="topic.dita" copy-to="topic2.dita"/>
```

On the other hand, it **will** report a warning if there is a topic referenced twice and none of the reference-type elements has a `@copy-to` attribute set or both of them have the `@copy-to` attribute set to the same value:

```
<topicref href="topic.dita" copy-to="topic2.dita"/>
......
 <topicref href="topic.dita" copy-to="topic2.dita"/>
```

Check for duplicate topic IDs within the DITA map context

Checks for multiple topics with the same ID in the context of the entire map.

Report duplicate key definitions

Checks the *DITA map* for multiple key references with the same key defined for them. This is helpful because if you have two different resources with the same value for the `@keys` attribute, all references will point to the first one encountered and the other will be ignored.

Note:
This option takes *key scopes (on page 3239)* into account. For example, if you have something like this:

```
<topicref href="t2.dita" keys="k2"/>
    <topicgroup keyscope="ks">
        <topicref href="t2.dita" keys="k2"/>
    </topicgroup>
```

it will not report the "k2" key as a duplicate because it is defined in a *key scope (on page 3239)* on the second occurrence.

Report unreferenced key definitions

Checks the entire *DITA map* and reports any key definitions that are not referenced anywhere. Note that if the **Use DITAVAL filters** option is selected, this check will search for unreferenced key definitions based upon your selected filter.

Report unreferenced reusable elements

Checks the entire *DITA map* and reports any detected reusable elements that are not referenced anywhere. It looks for elements that have an *ID* specified in the following types of topic references:

- Any `<topicref>` that contains a `@processing-role` attribute set to **resource-only**.
- Any other referenced topic that contains elements that are reused elsewhere through a `@conref` or `@conkeyref`.

Report table layout problems

Looks for table layout problems. The types of errors that may be reported include:

- If a row has fewer cells than the number of columns detected.
- For a *CALS* table, if a cell has a vertical span greater than the available rows count.
- For a *CALS* table, if the number of `<colspecs>` is different than the number of columns detected from the table `@cols` attribute.
- For a *CALS* table, if the number of columns detected from the table `@cols` attribute is different than the number of columns detected in the table structure.
- For a *CALS* table, if the value of the `@cols`, `@rowsep`, or `@colsep` attributes are not numeric.
- For a *CALS* table, if the `@namest`, `@nameend`, or `@colname` attributes point to an incorrect column name.

Identify possible conflicts in profile attribute values

When the profiling attributes of a topic contain values that are not found in parent topic profiling attributes, the content of the topic is overshadowed when generating profiled output. This option reports these possible conflicts.

Report attributes and values that conflict with profiling preferences

Looks for profiling attributes and values that are not defined in the **Profiling / Conditional Text** preferences page *(on page 195)* (you can click the **Profiling Preferences** button to open this preferences page). It also checks if profiling attributes defined as *single-value* have multiple values set in the searched topics.

Additional Schematron checks

Allows you to select a Schematron file that Oxygen XML Editor will use for the validation of DITA resources. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 332)* button, or the browsing actions in the **Browse** drop-down list.

> **Advanced Tip:**
> Some APIs are available that retrieve information about DITA keys that are referenced within a topic. The APIs can be called from XSLT Stylesheets (including XML Refactoring operations) or Schematron schemas. For details, see API Documentation: DITAXSLTExtensionFunctionUtil.

Move Up

Moves the selected validation unit up one spot in the list.

Move Down

Moves the selected validation unit down one spot in the list.

Add

Adds a new validation unit to the list.

Remove

Removes an existing validation unit from the list.

4. Configure any of the existing validation units according to the information above, and you can use the buttons at the bottom of the table to add, remove, or move validation units. Note that if you add a Schematron validation unit, you can also select the **validation phase**.
5. Click **Ok**.
   The newly created validation scenario is now included in the list of scenarios in the **Validation** tab *(on page 173)*. You can use the **Default** checkbox to specify that the new scenario be used as the default validation scenario when another specific scenario is not specified in the validation process.

Customizing New Document Templates for a Framework

You can create your own custom document templates and attach them to a custom *framework (on page 3420)*. You can then share the custom framework *(on page 2406)* so that all users will have access to the templates in the **New** document wizard *(on page 377)*.

To create your own custom document template and have it appear in the new document wizard, follow these steps:

1. Create a new file and customize it to become a starting point for creating new files of this type.

> **Tip:**
> You can use editor variables *(on page 332)* in the template file content and they will be expanded when the files are opened. Also, see Customizing Document Templates *(on page 387)* for other template customization tips (for example, you could add placeholders or hints *(on page 390)* to assist authors).

2. Save the new template in a directory (for example, called `templates`) within your custom framework directory.

   > **Attention:**
   > The name that you use to save the template will be the name that appears in the new document wizard, including capitalization, space, and characters (for example, `My Custom Template1.xml` will appear in the new file wizard as **My Custom Template1**). You can also configure the displayed name in a properties file by following the procedure found in the Configure the Displayed Names for Document Templates *(on page 389)* section.

3. Open the **Document Type** configuration dialog box *(on page 147)* for that specific framework, go to the **Templates** tab *(on page 170)*, and click the + button in the bottom-right corner to add your new directory to the list. It is recommended that the reference be made relative to the framework directory (for example, `${frameworkDir}/templates`). Binding to an absolute file (e. g.: `C:\some_dir\templates`) makes the association difficult to share between users.
4. Click **OK** for all of the dialog boxes to save your changes.
5. To test the template, open the new document wizard (**New** toolbar button or **File > New**) and you should see your custom template in the folder for your custom *framework* (in the **Framework templates** section).

Related information
Customizing Document Templates *(on page 387)*

Configuring XML Catalogs

For cases where you need to reference the location of a schema file from a remote web location and an Internet connection may not be available, an *XML Catalog (on page 3425)* may be used to map the web location to a local file system entry. The following procedure presents an example of using an *XML catalog* in a custom *framework (on page 3420)* by modifying an XML Schema file.

1. Create a catalog file that will help the parser locate the schema for validating the XML document. The file must map the location of the schema to a local version of the schema.
   Example:

   Create a new XML file called `catalog.xml` and save it in your custom *framework* directory (*`[OXYGEN_INSTALL_DIR]\frameworks\[CUSTOM_FRAMEWORK_DIR]`*). The content of the file should look like this:

```
<?xml version="1.0"?>
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
    <uri name="http://www.oxygenxml.com/SDF/abs.xsd"
            uri="schema/abs.xsd"/>
    <uri name="http://www.oxygenxml.com/SDF/abs.xsd"
```

```
            uri="schema/abs.xsd"/>
</catalog>
```

2. Add catalog files to your custom *framework* using the **Catalogs** tab *(on page 171)* from the **Document Type** configuration dialog box *(on page 147)*.

To test the catalog settings, restart Oxygen XML Editor and try to validate a new sample document for your custom *framework*. There should be no errors.

Example:

The schema that validates the document refers the other file `abs.xsd` through an **import** element:

```
<xs:import namespace=
 "http://www.oxygenxml.com/sample/documentation/abstracts"
 schemaLocation="http://www.oxygenxml.com/SDF/abs.xsd"/>
```

The `@schemaLocation` attribute references the `abs.xsd` file:

```
xsi:schemaLocation="http://www.oxygenxml.com/sample/documentation/abstracts"
    http://www.oxygenxml.com/SDF/abs.xsd"/>
```

The catalog mapping is:

```
http://www.oxygenxml.com/SDF/abs.xsd -> schema/abs.xsd
```

This means that all the references to http://www.oxygenxml.com/SDF/abs.xsd must be resolved to the `abs.xsd` file located in the `schema` directory (note that the `schema` directory needs to be in the same folder as the *XML Catalog*). The URI element is used by URI resolvers (for example, to resolve a URI reference used in an XSLT stylesheet).

Localizing Frameworks

Oxygen XML Editor supports *framework (on page 3420)* localization (translating *framework* actions, buttons, and menu entries to various languages). This lets you develop and distribute a *framework* to users that speak other languages without changing the distributed *framework*. Changing the language used in Oxygen XML Editor in the Global preferences page is enough to set the right language for each *framework*.

To localize the content of a *framework*, follow this procedure:

1. Create a `translation.xml` file that contains all the translation (key, value) mappings. The `translation.xml` has the following format:

```
<translation>
    <languageList>
        <language description="English" lang="en_US"/>
        <language description="German" lang="de_DE"/>
        <language description="French" lang="fr_FR"/>
    </languageList>
```

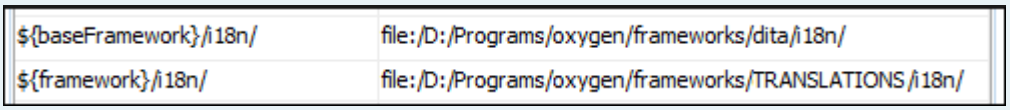
```
    <key value="list">
        <comment>List menu item name.</comment>
        <val lang="en_US">List</val>
        <val lang="de_DE">Liste</val>
        <val lang="fr_FR">Liste</val>
    </key>
.....................
</translation>
```

Oxygen XML Editor matches the GUI language with the language set in the `translation.xml` file. If this language is not found, the first available language declared in the `<languagelist>` tag for the corresponding *framework* is used.

2. The `translation.xml` file must be stored in a directory named `i18n` located in the framework folder. You also need to add a reference to the `i18n` directory in the **Classpath** list corresponding to the edited document type *(on page 152)*.

Note:

If you are working with an extension of a framework, you have to add the reference to your directory after (below) the reference to the `i18n` directory for the base directory:



3. After you create this file, you can use the keys defined in it to customize the name and description of the following:
    - Actions
    - Menu entries
    - Contextual menus
    - Toolbars
    - Static CSS content

    For example, if you want to localize the bold action, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association**. Use the **New** or **Edit** button to open the **Document type** configuration dialog box *(on page 147)*, go to **Author > Actions**, and rename the bold action to `${i18n(translation_key)}`. Actions with a name format other than `${i18n(translation_key)}` are not localized. *Translation_key* corresponds to the key from the `translation.xml` file.

4. Next, open the `translation.xml` file and edit the translation entry if it exists or create one if it does not exist. This is an example of an entry in the translation.xml file:

```
<key value="translation_key">
        <comment>Bold action name.</comment>
        <val lang="en_US">Bold</val>
        <val lang="de_DE">Bold</val>
        <val lang="fr_FR">Bold</val>
    </key>
```

To use a description from the `translation.xml` file in the Java code used by your custom *framework*, use the new *ro.sync.ecss.extensions.api.AuthorAccess.getAuthorResourceBundle()* API method to request the associated value for a certain key. This allows all the dialog boxes that you present from your custom operations to have labels translated in multiple languages.

You can also reference a key directly in the CSS content:

```
title:before{
    content:"${i18n(title.key)} : ";
}
```

Tip:
You can enter any language you want in the `<languagelist>` tag and any number of keys.

DocBook Example:

The `translation.xml` file for the DocBook *framework* is located here:*[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/i18n/translation.xml`. In the **Classpath** list corresponding to the DocBook document type, the following entry was added: `${framework}/i18n/`.

To see how the DocBook actions are defined to use these keys for their name and description, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association > Author > Actions**. If you look in the Java class *ro.sync.ecss.extensions.docbook.table.SADocbookTableCustomizerDialog* available in the *oxygen-sample-framework* module of the Oxygen SDK Maven archetype, you can see how the new *ro.sync.ecss.extensions.api.AuthorResourceBundle* API is used to retrieve localized descriptions for various keys.

Framework Java Extensibility Guide

Advanced users can extend the functionality of custom frameworks and **Author** mode. The *Oxygen SDK* is also available to provide developers the ability to extend the functionality of Oxygen XML Editor.

You can add *extensions (on page 3422)* to your custom *framework (on page 3420)* (document type) by using the **Extensions** tab from the **Document Type** configuration dialog box *(on page 147)*.

Note:
It is possible for a *plugin* to share the same classes with a *framework*. For further details, go to How to Share the Classloader Between a Framework and a Plugin *(on page 2564)*.

Related Information:
Extending Oxygen With the SDK *(on page 2530)*
SDK Common Use Cases *(on page 2597)*

Configuring an Extensions Bundle

All *extensions (on page 3422)* that are provided by Oxygen XML Editor are includes in a single bundle.

Note:
The individual extensions can still be set (open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, double-click a document type, and go to the extension tab), and if present, they take precedence over the single provider. However, this practice is discouraged and the single provider should be used instead.

The extensions bundle is represented by the *ro.sync.ecss.extensions.api.ExtensionsBundle* class. The provided implementation of the `ExtensionsBundle` is instantiated when the *Document Type Association (on page 3419)* rules defined for the custom *framework (on page 3420)* matches a document opened in the editor. Therefore, references to objects that need to be persistent throughout the application running session must not be kept in the bundle because the next detection event can result in creating another *ExtensionsBundle* instance.

To configure an extensions bundle, follow this procedure:

1. Create a new Java project in your IDE. Create a `lib` folder in the Java project folder and copy in it the `oxygen.jar` file from the *`[OXYGEN_INSTALL_DIR]/lib`* folder.
2. Create the class (for example, *simple.documentation.framework.SDFExtensionsBundle*) to extend the abstract class *ro.sync.ecss.extensions.api.ExtensionsBundle*.
   For example:
   ```
   public class SDFExtensionsBundle extends ExtensionsBundle {
   ```
3. A `Document Type ID` and a short description should be defined by implementing the *getDocumentTypeID* and *getDescription* methods. The `Document Type ID` is used to uniquely identify the current *framework*. Such an ID must be provided especially if options related to the *framework* need to be persistently stored and retrieved between sessions.
   For example:
   ```
   public String getDocumentTypeID() {
       return "Simple.Document.Framework.document.type";
   }
   ```

```
public String getDescription() {
    return "A custom extensions bundle used for the Simple Document" +
           "Framework document type";
}
```

4. **[Optional]** To be notified about the activation of the custom *Author Extension* in relation with an open document, *ro.sync.ecss.extensions.api.AuthorExtensionStateListener* should be implemented. The **activation** and **deactivation** events received by this listener should be used to perform custom initializations and to register or remove listeners such as *ro.sync.ecss.extensions.api.AuthorListener*, *ro.sync.ecss.extensions.api.AuthorMouseListener*, or *ro.sync.ecss.extensions.api.AuthorCaretListener*. The custom *Author Extension* state listener should be provided by implementing the *createAuthorExtensionStateListener* method.
   For example:

   ```
   public AuthorExtensionStateListener createAuthorExtensionStateListener() {
       return new SDFAuthorExtensionStateListener();
   }
   ```

   The `AuthorExtensionStateListener` is instantiated and notified about the activation of the *framework* when the rules of the *Document Type Association* match a document opened in the **Author** editing mode. The listener is notified about the deactivation when another *framework* is activated for the same document, the user switches to another mode or the editor is closed. A complete description and implementation of *ro.sync.ecss.extensions.api.AuthorExtensionStateListener* can be found in Implementing an Author Extension State Listener *(on page 2364)*.

   If Schema-Aware mode *(on page 188)* is active in Oxygen XML Editor, all actions that can generate invalid content will be redirected toward the *ro.sync.ecss.extensions.api.AuthorSchemaAwareEditingHandler*. The handler can resolve a specific case, let the default implementation take place, or reject the edit entirely by throwing *ro.sync.ecss.extensions.api.InvalidEditException*. The actions that are forwarded to this handler include typing, delete, or paste.

   For more details about this handler, see Handling Schema-Aware Editing Events *(on page 2401)*.

5. **[Optional]** You can customize the content completion proposals by creating a schema manager filter extension. The interface that declares the methods used for content completion proposals filtering is *ro.sync.contentcompletion.xml.SchemaManagerFilter*. The filter can be applied on elements, attributes, or on their values. The *createSchemaManagerFilter* method is responsible for creating the content completion filter. A new `SchemaManagerFilter` will be created each time a document matches the rules defined by the *Document Type Association* that contains the filter declaration.
   For example:

   ```
   public SchemaManagerFilter createSchemaManagerFilter() {
       return new SDFSchemaManagerFilter();
   }
   ```

A detailed presentation of the schema manager filter can be found in the Configuring a Content Completion Handler *(on page 2357)* section.

6. **[Optional]** The **Author** mode supports link-based navigation between documents and document sections. Therefore, if the document contains elements defined as links to other elements (for example, links based on the `@id` attributes), the extension should provide the means to find the referenced content. To do this, an implementation of the *ro.sync.ecss.extensions.api.link.ElementLocatorProvider* interface should be returned by the *createElementLocatorProvider* method. Each time an element pointed by a link needs to be located, the method is invoked.
   For example:

   ```
   public ElementLocatorProvider createElementLocatorProvider() {
       return new DefaultElementLocatorProvider();
   }
   ```

   For more information on how to implement an element locator provider, see the Configuring a Link Target Element Finder *(on page 2381)* section.

7. **[Optional]** The drag and drop functionality can be extended by implementing the *ro.sync.exml.editor.xmleditor.pageauthor.AuthorDnDListener* interface. Relevant methods from the listener are invoked when the mouse is dragged, moved over, or exits the **Author** editing mode, when the drop action changes, and when the drop occurs. Each method receives the `DropTargetEvent` containing information about the drag and drop operation. The drag and drop extensions are available in **Author** mode for both Oxygen XML Editor Eclipse plugin and standalone application. The **Text** mode corresponding listener is available only for Oxygen XML Editor Eclipse plugin. The methods corresponding to each implementation are: *createAuthorAWTDndListener*, *createTextSWTDndListener*, and *createAuthorSWTDndListener*.

   ```
   public AuthorDnDListener createAuthorAWTDndListener() {
       return new SDFAuthorDndListener();
   }
   ```

   For more details about the **Author** mode drag and drop listeners, see the Configuring a custom Drag and Drop Listener *(on page 2359)* section.

8. **[Optional]** Another extension that can be included in the bundle is the reference resolver. For example, the references represented by the **ref** element and the attribute indicating the referenced resource is **location**. To be able to obtain the content of the referenced resources you will have to implement a Java extension class that implements *ro.sync.ecss.extensions.api.AuthorReferenceResolver*. The method responsible for creating the custom references resolver is *createAuthorReferenceResolver*. The method is called each time a document opened in an **Author** editing mode matches the *Document Type Association* where the extensions bundle is defined. The instantiated references resolver object is kept and used until another extensions bundle corresponding to another document type is activated as result of the detection process.
   For example:

```
public AuthorReferenceResolver createAuthorReferenceResolver() {
    return new ReferencesResolver();
}
```

A more detailed description of the references resolver can be found in the Configuring a References Resolver *(on page 2360)* section.

9. **[Optional]** To be able to dynamically customize the default CSS styles for a certain *ro.sync.ecss.extensions.api.node.AuthorNode*, an implementation of *ro.sync.ecss.extensions.api.StylesFilter* can be provided. The extensions bundle method responsible for creating the `StylesFilter` is *createAuthorStylesFilter*. The method is called each time a document opened in an **Author** editing mode matches the *Document Type Association* where the extensions bundle is defined. The instantiated filter object is kept and used until another extensions bundle corresponding to another document type is activated as a result of the detection process.
   For example:

   ```
   public StylesFilter createAuthorStylesFilter() {
       return new SDFStylesFilter();
   }
   ```

   See the Configuring CSS Styles Filter *(on page 2380)* section for more details about the styles filter extension.

10. **[Optional]** To edit data in custom tabular format, implementations of the *ro.sync.ecss.extensions.api.AuthorTableCellSpanProvider* and the *ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider* interfaces should be provided.
    The two methods from the `ExtensionsBundle` specifying these two extension points are *createAuthorTableCellSpanProvider* and *createAuthorTableColumnWidthProvider*.
    For example:

    ```
    public AuthorTableCellSpanProvider createAuthorTableCellSpanProvider() {
        return new TableCellSpanProvider();
    }

    public AuthorTableColumnWidthProvider
        createAuthorTableColumnWidthProvider() {
        return new TableColumnWidthProvider();
    }
    ```

    The two table information providers are not reused for different tables. The methods are called for each table in the document so new instances should be provided every time. Read more about the cell span and column width information providers in Configuring a Table Cell Span Provider *(on page 2373)* and Configuring a Table Column Width Provider *(on page 2367)* sections.

If the functionality related to one of the previous extension points does not need to be modified, then the developed *ro.sync.ecss.extensions.api.ExtensionsBundle* should not override the corresponding method and leave the default base implementation to return **null**.

11. **[Optional]** An XML vocabulary can contain links to various areas of a document. If the document contains elements defined as links, you can choose to present a more relevant text description for each link. To do this, an implementation of the *ro.sync.ecss.extensions.api.link.LinkTextResolver* interface should be returned by the *createLinkTextResolver* method. This implementation is used each time the *oxy_link-text() function (on page 2483)* is encountered in the CSS styles associated with an element. For example:

    ```
    public LinkTextResolver createLinkTextResolver() {
      return new DitaLinkTextResolver();
    }
    ```

    Oxygen XML Editor offers built-in implementations for DITA and DocBook: *ro.sync.ecss.extensions.dita.link.DitaLinkTextResolver* and *ro.sync.ecss.extensions.docbook.link.DocbookLinkTextResolver* respectively.

12. Pack the compiled class into a *JAR (on page 3420)* file.
13. Copy the *JAR* file into your custom *framework* directory (for example, `frameworks/sdf`).
14. Add the *JAR* file to the class path. To do this, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, select the document type (for example, *SDF*), click the **Edit** button, select the **Classpath** tab, and click the **Add** button. In the displayed dialog box, enter the location of the *JAR* file relative to the Oxygen XML Editor `frameworks` folder.
15. Register the Java class by going to the **Extensions** tab. Click the **Choose** button and select the name of the class (for example, *SDFExtensionsBundle*).

    Note:
    The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Sample DITA (framework) extension that sets a custom `ExtensionsBundle` implementation for customizing links

Adding a Custom Image Decorator for Author Mode

The *AuthorImageDecorator* extension point allows you to add a custom decorator over images in **Author** mode. For example, you could use it to add a message over an image informing the user that they can double-click the image to edit it.

How to Implement an *AuthorImageDecorator*

To implement your own *AuthorImageDecorator*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.AuthorImageDecorator* interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
    a. If you have configured an extensions bundle *(on page 2350)*, you can return the *AuthorImageDecorator* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.getAuthorImageDecorator()* method.
    b. Specify the *AuthorImageDecorator* in the **Author image decorator** individual extension in the **Extensions** tab *(on page 174)* of the **Document Type** configuration dialog box *(on page 147)* for your particular document type.

Example

The following example illustrates an implementation for presenting a simple message over an image that informs the user that they can double-click the image to edit it:

```
/**
 * Custom Author image decorator for drawing string over images.
 */
public class CustomAuthorImageDecorator extends AuthorImageDecorator {

  /**
   * @see ro.sync.ecss.extensions.api.AuthorImageDecorator#paint
(ro.sync.exml.view.graphics.Graphics, int, int, int, int,
 ro.sync.exml.view.graphics.Rectangle,
 ro.sync.ecss.extensions.api.node.AuthorNode,
 ro.sync.ecss.extensions.api.AuthorAccess, boolean)
   */
  @Override
  public void paint(Graphics g, int x, int y, int imageWidth, int imageHeight,
      Rectangle originalSize, AuthorNode element,
 AuthorAccess authorAccess, boolean wasAnnotated) {
    if ("image".equals(CommonsOperationsUtil.getLocalName(element.getName()))) {
      g.drawString(
          "[Double-click to edit image]",
          // Draw near the top-left corner
          x + 15,
          y + 15);
    }
  }
```

Example result: In the top-left corner of the image, the following message will be displayed: `[Double-click to edit image]`.

Adding Custom Persistent Highlights

The *Author API* includes a class that allows you to create or remove custom persistent highlights, set new properties for the highlights, and customize their appearance. An example of a possible use case would be if you want to implement your own way of editing review comments. The custom persistent highlights get serialized in the XML document as processing instructions, with the following format:

```
<?oxy_custom_start prop1="val1"....?> xml content <?oxy_custom_end?>
```

This functionality is available through the *AuthorPersistentHighlighter* class that is accessible through the *AuthorEditorAccess#getPersistentHighlighter()* method.

For more information, see the JavaDoc details for this class at https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/highlights/AuthorPersistentHighlighter.html.

Configuring the Automatic ID Generation and Unique Attributes Recognizer

The *ro.sync.ecss.extensions.api.UniqueAttributesRecognizer* interface can be implemented if you want to provide for your *framework (on page 3420)* the following features:

- **Automatic ID generation** - You can automatically generate unique IDs for newly inserted elements. Implementations are already available for the DITA and DocBook *frameworks (on page 3420)*. The following methods can be implemented to accomplish this: *assignUniqueIDs(int startOffset, int endOffset)*, *isAutoIDGenerationActive()*
- **Avoiding copying unique attributes when "Split" is called inside an element** - You can split the current *block element (on page 3417)* by pressing the "Enter" key and then choosing "Split". This is a very useful way to create new paragraphs, for example. All attributes are by default copied on the new element but if those attributes are IDs you sometimes want to avoid creating validation errors in the editor. Implementing the following method, you can decide whether or not an attribute should be copied during the split: *boolean copyAttributeOnSplit(String attrQName, AuthorElement element)*

  > **Tip:**
  > The *ro.sync.ecss.extensions.commons.id.DefaultUniqueAttributesRecognizer* class is an implementation of the interface that can be extended by your customization to provide easy assignation of IDs in your *framework (on page 3420)*. You can also check out the DITA and DocBook implementations of *ro.sync.ecss.extensions.api.UniqueAttributesRecognizer* to see how they were implemented and connected to the extensions bundle.

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Configuring Content Completion Proposals

You can filter or contribute to proposals offered for content completion by implementing the *ro.sync.contentcompletion.xml.SchemaManagerFilter* interface.

```
import java.util.List;

import ro.sync.contentcompletion.xml.CIAttribute;
import ro.sync.contentcompletion.xml.CIElement;
import ro.sync.contentcompletion.xml.CIValue;
import ro.sync.contentcompletion.xml.Context;
import ro.sync.contentcompletion.xml.SchemaManagerFilter;
import ro.sync.contentcompletion.xml.WhatAttributesCanGoHereContext;
import ro.sync.contentcompletion.xml.WhatElementsCanGoHereContext;
import ro.sync.contentcompletion.xml.WhatPossibleValuesHasAttributeContext;

public class SDFSchemaManagerFilter implements SchemaManagerFilter {
```

You can implement the various callbacks of the interface either by returning the default values given by Oxygen XML Editor or by contributing to the list of proposals. The filter can be applied on elements, attributes or on their values. Attributes filtering can be implemented using the *filterAttributes* method and changing the default content completion list of *ro.sync.contentcompletion.xml.CIAttribute* for the element provided by the current *ro.sync.contentcompletion.xml.WhatAttributesCanGoHereContext* context. For example, the `SDFSchemaManagerFilter` checks if the element from the current context is the `table` element and adds the `frame` attribute to the `table` list of attributes.

```
/**
 * Filter attributes of the "table" element.
 */
public List<CIAttribute> filterAttributes(List<CIAttribute> attributes,
    WhatAttributesCanGoHereContext context) {
  // If the element from the current context is the 'table' element add the
  // attribute named 'frame' to the list of default content completion proposals
  if (context != null) {
    ContextElement contextElement = context.getParentElement();
    if ("table".equals(contextElement.getQName())) {
      CIAttribute frameAttribute = new CIAttribute();
      frameAttribute.setName("frame");
      frameAttribute.setRequired(false);
```

```
      frameAttribute.setFixed(false);
      frameAttribute.setDefaultValue("void");
      if (attributes == null) {
        attributes = new ArrayList<CIAttribute>();
      }
      attributes.add(frameAttribute);
    }
  }
  return attributes;
}
```

The elements that can be inserted in a specific context can be filtered using the *filterElements* method. The `SDFSchemaManagerFilter` uses this method to replace the `td` child element with the `th` element when `header` is the current context element.

```
public List<CIElement> filterElements(List<CIElement> elements,
    WhatElementsCanGoHereContext context) {
  // If the element from the current context is the 'header' element remove the
  // 'td' element from the list of content completion proposals and add the
  // 'th' element.
  if (context != null) {
    Stack<ContextElement> elementStack = context.getElementStack();
    if (elementStack != null) {
      ContextElement contextElement = context.getElementStack().peek();
      if ("header".equals(contextElement.getQName())) {
        if (elements != null) {
          for (Iterator<CIElement> iterator =
elements.iterator(); iterator.hasNext();) {
            CIElement element = iterator.next();
            // Remove the 'td' element
            if ("td".equals(element.getQName())) {
              elements.remove(element);
              break;
            }
          }
        } else {
          elements = new ArrayList<CIElement>();
        }
        // Insert the 'th' element in the list of content completion proposals
        CIElement thElement = new SDFElement();
        thElement.setName("th");
        elements.add(thElement);
      }
```

```
    }
  } else {
    // If the given context is null then the given list of content completion
    // elements contains global elements.
  }
  return elements;
}
```

The elements or attributes values can be filtered using the *filterElementValues* or *filterAttributeValues* methods.

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Configuring a Custom Drag and Drop Listener

Sometimes it is useful to perform various operations when certain objects are dropped from outside sources in the editing area. You can choose from three interfaces to implement depending on whether you are using the Eclipse plugin or the standalone version of the application, or if you want to add the handler for the **Text** or **Author** modes.

Interfaces for the Drag and Drop Listener

ro.sync.exml.editor.xmleditor.pageauthor.AuthorDnDListener

Receives callbacks from the standalone application for Drag And Drop in **Author** mode.

com.oxygenxml.editor.editors.author.AuthorDnDListener

Receives callbacks from the Eclipse plugin for Drag And Drop in **Author** mode.

com.oxygenxml.editor.editors.TextDnDListener

Receives callbacks from the Eclipse plugin for Drag And Drop in **Text** mode.

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

To configure how dropped URLs or XHTML fragments are handled in documents, see Handling When URLs or XHTML Fragments are Dropped or Pasted in Author Mode *(on page 2403)*.

Related Information:
Customizing Smart Paste Support *(on page 2306)*

Configuring a Reference Resolver

This information is helpful if you need to provide a handler for resolving references and obtain the content they reference. For example, suppose the element that has references is **ref** and the attribute indicating the referenced resource is **location**. You need to implement a Java extension class for obtaining the referenced resources.

1. Create the class *simple.documentation.framework.ReferencesResolver*. This class must implement the *ro.sync.ecss.extensions.api.AuthorReferenceResolver* interface.

```
import ro.sync.ecss.extensions.api.AuthorReferenceResolver;
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.node.AttrValue;
import ro.sync.ecss.extensions.api.node.AuthorElement;
import ro.sync.ecss.extensions.api.node.AuthorNode;

public class ReferencesResolver
      implements AuthorReferenceResolver {
```

2. The *hasReferences* method verifies if the handler considers the node to have references. It takes *AuthorNode* as an argument that represents the node that will be verified. The method will return `true` if the node is considered to have references. In the following example, to be a reference, the node must be an element with the name *ref* and it must have an attribute named *location*.

```
public boolean hasReferences(AuthorNode node) {
  boolean hasReferences = false;
  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
    if ("ref".equals(element.getLocalName())) {
      AttrValue attrValue = element.getAttribute("location");
      hasReferences = attrValue != null;
    }
  }
  return hasReferences;
}
```

3. The method *getDisplayName* returns the display name of the node that contains the expanded referenced content. It takes *AuthorNode* as an argument that represents the node that needs the display name. The referenced content engine will ask this *AuthorReferenceResolver* implementation for the display name for each node that is considered a reference. In the following example, the display name is the value of the *location* attribute from the *ref* element.

```
public String getDisplayName(AuthorNode node) {
  String displayName = "ref-fragment";
  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
```

```
    if ("ref".equals(element.getLocalName())) {
      AttrValue attrValue = element.getAttribute("location");
      if (attrValue != null) {
        displayName = attrValue.getValue();
      }
    }
  }
  return displayName;
}
```

4. The method *resolveReference* resolves the reference of the node and returns a *SAXSource* with the parser and its input source. It takes *AuthorNode* as an argument that represents the node that needs the reference resolved, the `systemID` of the node, the *AuthorAccess* with access methods to the **Author** mode data model and a SAX *EntityResolver* that resolves resources that are already opened in another editor or resolve resources through the *XML Catalog (on page 3425)*. In the implementation, you need to resolve the reference relative to the `systemID`, and create a parser and an input source over the resolved reference.

```
public SAXSource resolveReference(
    AuthorNode node,
    String systemID,
    AuthorAccess authorAccess,
    EntityResolver  entityResolver) {
  SAXSource saxSource = null;

  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
    if ("ref".equals(element.getLocalName())) {
      AttrValue attrValue = element.getAttribute("location");
      if (attrValue != null) {
        String attrStringVal = attrValue.getValue();
        try {
          URL absoluteUrl = new URL(new URL(systemID),
          authorAccess.getUtilAccess().correctURL(attrStringVal));

          InputSource inputSource = entityResolver.resolveEntity(null,
              absoluteUrl.toString());
          if(inputSource == null) {
            inputSource = new InputSource(absoluteUrl.toString());
          }

          XMLReader xmlReader = authorAccess.newNonValidatingXMLReader();
          xmlReader.setEntityResolver(entityResolver);
```

```
          saxSource = new SAXSource(xmlReader, inputSource);
        } catch (MalformedURLException e) {
          logger.error(e, e);
        } catch (SAXException e) {
          logger.error(e, e);
        } catch (IOException e) {
          logger.error(e, e);
        }
      }
    }
  }

  return saxSource;
}
```

5. The method *getReferenceUniqueID* should return a unique identifier for the node reference. The unique identifier is used to avoid resolving the references recursively. The method takes *AuthorNode* as an argument that represents the node with the reference. In the following example, the unique identifier is the value of the *location* attribute from the *ref* element.

```
public String getReferenceUniqueID(AuthorNode node) {
  String id = null;
  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
    if ("ref".equals(element.getLocalName())) {
      AttrValue attrValue = element.getAttribute("location");
      if (attrValue != null) {
        id = attrValue.getValue();
      }
    }
  }
  return id;
}
```

6. The method *getReferenceSystemID*should return the `systemID` of the referenced content. It takes *AuthorNode* as an argument that represents the node with the reference and the *AuthorAccess* with access methods to the **Author** mode data model. For example, the value of the *location* attribute is used from the *ref* element and resolved relatively to the XML base URL of the node.

```
public String getReferenceSystemID(AuthorNode node,
                                   AuthorAccess authorAccess) {
  String systemID = null;
  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
    if ("ref".equals(element.getLocalName())) {
```

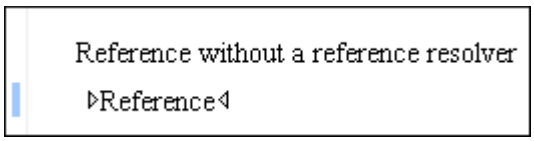
```
      AttrValue attrValue = element.getAttribute("location");
      if (attrValue != null) {
        String attrStringVal = attrValue.getValue();
        try {
          URL absoluteUrl = new URL(node.getXMLBaseURL(),
              authorAccess.getUtilAccess().correctURL(attrStringVal));
          systemID = absoluteUrl.toString();
        } catch (MalformedURLException e) {
          logger.error(e, e);
        }
      }
    }
  }
  return systemID;
}
```

In the listing below, the XML document contains the **ref** element:

```
<ref location="referenced.xml">Reference</ref>
```

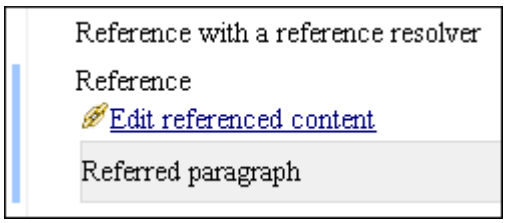
When no reference resolver is specified, the reference has the following layout:

Figure 603. Reference with no specified reference resolver



When the above implementation is configured, the reference has the expected layout:

Figure 604. Reference with reference resolver



Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Configuring a State Listener for Author Mode

The *ro.sync.ecss.extensions.api.AuthorExtensionStateListener* implementation is notified when the **Author** mode extension (where the listener is defined) is activated or deactivated in the document type detection process.

```
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.AuthorExtensionStateListener;

public class SDFAuthorExtensionStateListener implements
  AuthorExtensionStateListener {
  private AuthorListener sdfAuthorDocumentListener;
  private AuthorMouseListener sdfMouseListener;
  private AuthorCaretListener sdfCaretListener;
  private OptionListener sdfOptionListener;
```

When the association rules of the *framework (on page 3420)* (document type) configuration match that of a document open in the **Author** editing mode, the *activation* event received by this listener should be used to perform custom initializations and to register listeners such as *ro.sync.ecss.extensions.api.AuthorListener*, *ro.sync.ecss.extensions.api.AuthorMouseListener*, or *ro.sync.ecss.extensions.api.AuthorCaretListener*.

```
public void activated(AuthorAccess authorAccess) {
  // Get the value of the option.
  String option = authorAccess.getOptionsStorage().getOption(
              "sdf.custom.option.key", "");
  // Use the option for some initializations...

  // Add an OptionListener.
  authorAccess.getOptionsStorage().addOptionListener(sdfOptionListener);

  // Add author DocumentListeners.
  sdfAuthorDocumentListener = new SDFAuthorListener();
  authorAccess.getDocumentController().addAuthorListener(
              sdfAuthorDocumentListener);

  // Add MouseListener.
  sdfMouseListener = new SDFAuthorMouseListener();
  authorAccess.getEditorAccess().addAuthorMouseListener(sdfMouseListener);

  // Add CaretListener.
  sdfCaretListener = new SDFAuthorCaretListener();
  authorAccess.getEditorAccess().addAuthorCaretListener(sdfCaretListener);

  // Other custom initializations...
```

```
}
```

The `authorAccess` parameter received by the *activated* method can be used to gain access to specific **Author** mode actions and informations related to components such as the editor, document, workspace, tables, or the *change tracking* manager.

If options specific to the custom developed *Author Extension* need to be stored or retrieved, a reference to the *ro.sync.ecss.extensions.api.OptionsStorage* can be obtained by calling the *getOptionsStorage* method from the **authorAccess**. The same object can be used to register *ro.sync.ecss.extensions.api.OptionListener* listeners. An option listener is registered in relation with an option **key** and will be notified about the value changes of that option.

An *AuthorListener* can be used if events related to the **Author** mode document modifications are of interest. The listener can be added to the *ro.sync.ecss.extensions.api.AuthorDocumentController*. A reference to the document controller is returned by the *getDocumentController* method from the **authorAccess**. The document controller can also be used to perform operations involving document modifications.

To provide access to the **Author** mode component-related functionality and information, the **authorAccess** has a reference to the *ro.sync.ecss.extensions.api.access.AuthorEditorAccess* that can be obtained when calling the *getEditorAccess* method. At this level, *AuthorMouseListener* and *AuthorCaretListener* can be added to provide notification of mouse and cursor events that occur in the **Author** editor mode.

The *deactivation* event is received when another *framework* is activated for the same document, the user switches to another editor mode or the editor is closed. The *deactivate* method is typically used to unregister the listeners previously added on the *activate* method and to perform other actions. For example, options related to the deactivated *Author Extension* can be saved at this point.

```
public void deactivated(AuthorAccess authorAccess) {
  // Store the option.
  authorAccess.getOptionsStorage().setOption(
              "sdf.custom.option.key", optionValue);

  // Remove the OptionListener.
  authorAccess.getOptionsStorage().removeOptionListener(sdfOptionListener);

  // Remove DocumentListeners.
  authorAccess.getDocumentController().removeAuthorListener(
              sdfAuthorDocumentListener);

  // Remove MouseListener.
  authorAccess.getEditorAccess().removeAuthorMouseListener(sdfMouseListener);

  // Remove CaretListener.
  authorAccess.getEditorAccess().removeAuthorCaretListener(sdfCaretListener);
```

```
  // Other actions...

}
```

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Configuring Tables

There are standard CSS properties used to indicate what elements are tables, table rows and table cells. What CSS is missing is the possibility to indicate the cell spanning, row separators or the column widths. Oxygen XML Editor offers support for adding extensions to solve these problems.

The table in this example is a simple one. The header must be formatted in a different way than the ordinary rows, so it will have a background color.

```
table{
    display:table;
    border:1px solid navy;
    margin:1em;
    max-width:1000px;
    min-width:150px;
}

table[width]{
  width:attr(width, length);
}

tr, header{
    display:table-row;
}

header{
    background-color: silver;
    color:inherit
}

td{
  display:table-cell;
  border:1px solid navy;
```

```
  padding:1em;
}
```

Suppose that in the schema, the `<td>` tag has the attributes `@row_span` and `@column_span` that are not automatically recognized by Oxygen XML Editor, a Java extension will be implemented that will provide information about the cell spanning. See the section Configuring a Table Cell Span Provider *(on page 2373)*.

Suppose the column widths are specified by the `@width` attribute of the `<customcol>` elements that are not automatically recognized by Oxygen XML Editor. It is necessary to implement a Java extension that will provide information about the column widths. For more information, see Configuring a Table Column Width Provider *(on page 2367)*.

The table from the example does not make use of the attributes `@colsep` and `@rowsep` (which are automatically recognized) but if you want the rows to be separated by horizontal lines, it is necessary to implement a Java extension that will provide information about the row and column separators. For more information, see Configuring a Table Cell Row and Column Separator Provider *(on page 2376)*.

Configuring a Table Column Width Provider

In a custom *framework (on page 3420)*, the `<table>` element as well as the table columns can have specified widths. For these widths to be considered by **Author** mode, you need to provide the means for determining them. As explained in Configuring Tables *(on page 2366)*, if you use the table element attribute **width** Oxygen XML Editor can determine the table width automatically. In this example the table has `<col>` elements with `@width` attributes that are not recognized by default. You will need to implement a Java extension class to determine the column widths.

1. Create the class *simple.documentation.framework.TableColumnWidthProvider*. This class must implement the *ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider* interface.

   ```
   import ro.sync.ecss.extensions.api.AuthorAccess;
   import ro.sync.ecss.extensions.api.AuthorOperationException;
   import ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider;
   import ro.sync.ecss.extensions.api.WidthRepresentation;
   import ro.sync.ecss.extensions.api.node.AuthorElement;

   public class TableColumnWidthProvider
         implements AuthorTableColumnWidthProvider {
   ```

2. Method *init* is taking as argument an *ro.sync.ecss.extensions.api.node.AuthorElement* that represents the XML `<table>` element. In our case the column widths are specified in `<col>` elements from the `<table>` element. In such cases you must collect the span information by analyzing the `<table>` element.

   ```
   public void init(AuthorElement tableElement) {
     this.tableElement = tableElement;
     AuthorElement[] colChildren = tableElement.getElementsByLocalName("customcol");
     if (colChildren != null && colChildren.length > 0) {
   ```

```
    for (int i = 0; i < colChildren.length; i++) {
      AuthorElement colChild = colChildren[i];
      if (i == 0) {
        colsStartOffset = colChild.getStartOffset();
      }
      if (i == colChildren.length - 1) {
        colsEndOffset = colChild.getEndOffset();
      }
      // Determine the 'width' for this col.
      AttrValue colWidthAttribute = colChild.getAttribute("width");
      String colWidth = null;
      if (colWidthAttribute != null) {
        colWidth = colWidthAttribute.getValue();
        // Add WidthRepresentation objects for the columns this 'customcol'
        //  specification spans over.
        colWidthSpecs.add(new WidthRepresentation(colWidth, true));
      }
    }
  }
}
```

3. The method *isTableAcceptingWidth* should check if the table cells are a `<td>` element.

```
public boolean isTableAcceptingWidth(String tableCellsTagName) {
  return "td".equals(tableCellsTagName);
}
```

4. The method *isTableAndColumnsResizable* should check if the table cells are a `<td>` element. This method determines if the table and its columns can be resized by dragging the edge of a column.

```
public boolean isTableAndColumnsResizable(String tableCellsTagName) {
  return "td".equals(tableCellsTagName);
}
```

5. Methods *getTableWidth* and *getCellWidth* are used to determine the table and column width. The table layout engine will ask this *ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider* implementation what is the table width for each table element and the cell width for each cell element from the table that was marked as cell in the CSS using the property `display:table-cell`. The implementation is simple and just parses the value of the **width** attribute. The methods must return `null` for the tables / cells that do not have a specified width.

```
public WidthRepresentation getTableWidth(String tableCellsTagName) {
  WidthRepresentation toReturn = null;
  if (tableElement != null && "td".equals(tableCellsTagName)) {
  AttrValue widthAttr = tableElement.getAttribute("width");
    if (widthAttr != null) {
```

```
      String width = widthAttr.getValue();
      if (width != null) {
        toReturn = new WidthRepresentation(width, true);
      }
    }
  }
  return toReturn;
}
```

```
public List<WidthRepresentation>
getCellWidth(AuthorElement cellElement, int colNumberStart,
  int colSpan) {
  List<WidthRepresentation> toReturn = null;
  int size = colWidthSpecs.size();
  if (size >= colNumberStart && size >= colNumberStart + colSpan) {
    toReturn = new ArrayList<WidthRepresentation>(colSpan);
    for (int i = colNumberStart; i < colNumberStart + colSpan; i ++) {
      // Add the column widths
      toReturn.add(colWidthSpecs.get(i));
    }
  }
  return toReturn;
}
```

6. Methods *commitTableWidthModification* and *commitColumnWidthModifications* are used to commit changes made to the width of the table or its columns when using the mouse drag gestures.

```
public void commitTableWidthModification
(AuthorDocumentController authorDocumentController,
  int newTableWidth, String tableCellsTagName) throws AuthorOperationException {
  if ("td".equals(tableCellsTagName)) {
    if (newTableWidth > 0) {
      if (tableElement != null) {
        String newWidth = String.valueOf(newTableWidth);
        authorDocumentController.setAttribute("width", new AttrValue(newWidth),
                                              tableElement);
      } else {
        throw new AuthorOperationException("Cannot find the table element.");
      }
    }
  }
}
```

```
public void commitColumnWidthModifications
  (AuthorDocumentController authorDocumentController,
```

```
  WidthRepresentation[] colWidths, String tableCellsTagName)
  throws AuthorOperationException {
  if ("td".equals(tableCellsTagName)) {
    if (colWidths != null && tableElement != null) {
      if (colsStartOffset >= 0 && colsEndOffset >= 0
&& colsStartOffset < colsEndOffset) {
        authorDocumentController.delete(colsStartOffset, colsEndOffset);
      }
      String xmlFragment = createXMLFragment(colWidths);
      int offset = -1;
      AuthorElement[] header = tableElement.getElementsByLocalName("header");
      if (header != null && header.length > 0) {
        // Insert the cols elements before the 'header' element
        offset = header[0].getStartOffset();
      }
      if (offset == -1) {
        throw new AuthorOperationException(
          "No valid offset to insert column width");
      }
      authorDocumentController.insertXMLFragment(xmlFragment, offset);
    }
  }
}

private String createXMLFragment(WidthRepresentation[] widthRepresentations) {
  StringBuffer fragment = new StringBuffer();
  String ns = tableElement.getNamespace();
  for (int i = 0; i < widthRepresentations.length; i++) {
    WidthRepresentation width = widthRepresentations[i];
    fragment.append("<customcol");
    String strRepresentation = width.getWidthRepresentation();
    if (strRepresentation != null) {
      fragment.append(" width=\"" + width.getWidthRepresentation() + "\"");
    }
    if (ns != null && ns.length() > 0) {
      fragment.append(" xmlns=\"" + ns + "\"");
    }
    fragment.append("/>");
  }
  return fragment.toString();
}
```

7. The following three methods are used to determine what type of column width specifications the table column width provider support. In our case all types of specifications are allowed:

```
public boolean isAcceptingFixedColumnWidths(String tableCellsTagName) {
  return true;
}

public boolean isAcceptingPercentageColumnWidths(String tableCellsTagName) {
  return true;
}

public boolean isAcceptingProportionalColumnWidths(String tableCellsTagName) {
  return true;
}
```

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

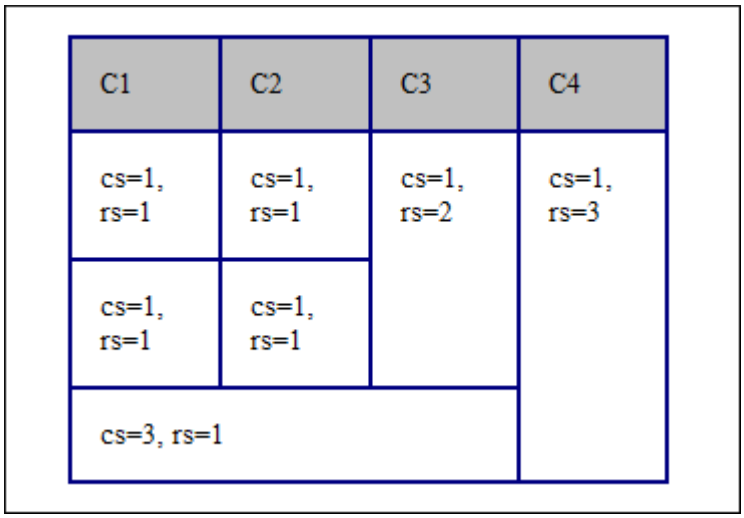
In the listing below, the XML document contains the table element:

```
<table width="300">
    <customcol width="50.0px"/>
    <customcol width="1*"/>
    <customcol width="2*"/>
    <customcol width="20%"/>
    <header>
        <td>C1</td>
        <td>C2</td>
        <td>C3</td>
        <td>C4</td>
    </header>
    <tr>
        <td>cs=1, rs=1</td>
        <td>cs=1, rs=1</td>
        <td row_span="2">cs=1, rs=2</td>
        <td row_span="3">cs=1, rs=3</td>
    </tr>
    <tr>
        <td>cs=1, rs=1</td>
        <td>cs=1, rs=1</td>
    </tr>
```

```
    <tr>
        <td column_span="3">cs=3, rs=1</td>
    </tr>
</table>
```

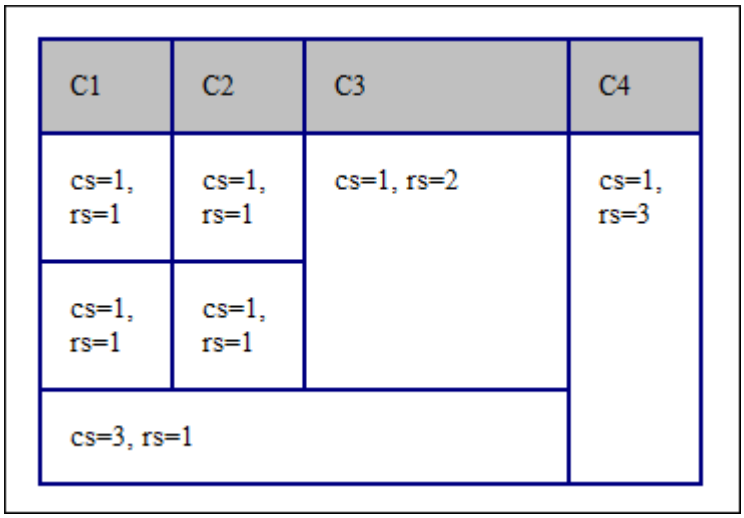
When no table column width provider is specified, the table has the following layout:

Figure 605. Table layout when no column width provider is specified



When the above implementation is configured, the table has the correct layout:

Figure 606. Columns with custom widths



Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Configuring a Table Cell Span Provider

In a custom *framework (on page 3420)*, the `<table>` element can have cells that span over multiple columns and rows. As explained in Configuring Tables *(on page 2366)*, you need to indicate Oxygen XML Editor a method to determine the cell spanning. If you use the `@rowspan` and `@colspan` attributes, Oxygen XML Editor can determine the cell spanning automatically. In the following example, the `<td>` element uses the `@row_span` and `@column_span` attributes that are not recognized by default. You will need to implement a Java extension class for defining the cell spanning.

1. Create the class *simple.documentation.framework.TableCellSpanProvider*. This class must implement the *ro.sync.ecss.extensions.api.AuthorTableCellSpanProvider* interface.

```
import ro.sync.ecss.extensions.api.AuthorTableCellSpanProvider;
import ro.sync.ecss.extensions.api.node.AttrValue;
import ro.sync.ecss.extensions.api.node.AuthorElement;

public class TableCellSpanProvider
      implements AuthorTableCellSpanProvider {
```

2. The *init* method takes *ro.sync.ecss.extensions.api.node.AuthorElement* that represents the XML `<table>` element as its argument. In this example, the cell span is specified for each of the cells so you leave this method empty. However, there are cases (such as the CALS table model) when the cell spanning is specified in the `<table>` element. In such cases, you must collect the span information by analyzing the `<table>` element.

```
public void init(AuthorElement table) {
}
```

3. The *getColSpan* method is taking as argument the table cell. The table layout engine will ask this *AuthorTableSpanSupport* implementation what is the column span and the row span for each XML element from the table that was marked as cell in the CSS using the property `display:table-cell`. The implementation is simple and just parses the value of **column_span** attribute. The method must return `null` for all the cells that do not change the span specification.

```
public Integer getColSpan(AuthorElement cell) {
  Integer colSpan = null;

  AttrValue attrValue = cell.getAttribute("column_span");
  if(attrValue != null) {
    // The attribute was found.
    String cs = attrValue.getValue();
    if(cs != null) {
      try {
        colSpan = new Integer(cs);
      } catch (NumberFormatException ex) {
        // The attribute value was not a number.
```

```
      }
    }
  }
  return colSpan;
}
```

4. The row span is determined in a similar manner:

```
public Integer getRowSpan(AuthorElement cell) {
  Integer rowSpan = null;

  AttrValue attrValue = cell.getAttribute("row_span");
  if(attrValue != null) {
    // The attribute was found.
    String rs = attrValue.getValue();
    if(rs != null) {
      try {
        rowSpan = new Integer(rs);
      } catch (NumberFormatException ex) {
        // The attribute value was not a number.
      }
    }
  }
  return rowSpan;
}
```

5. The method *hasColumnSpecifications* always returns `true` considering column specifications always available.

```
public boolean hasColumnSpecifications(AuthorElement tableElement) {
  return true;
}
```

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

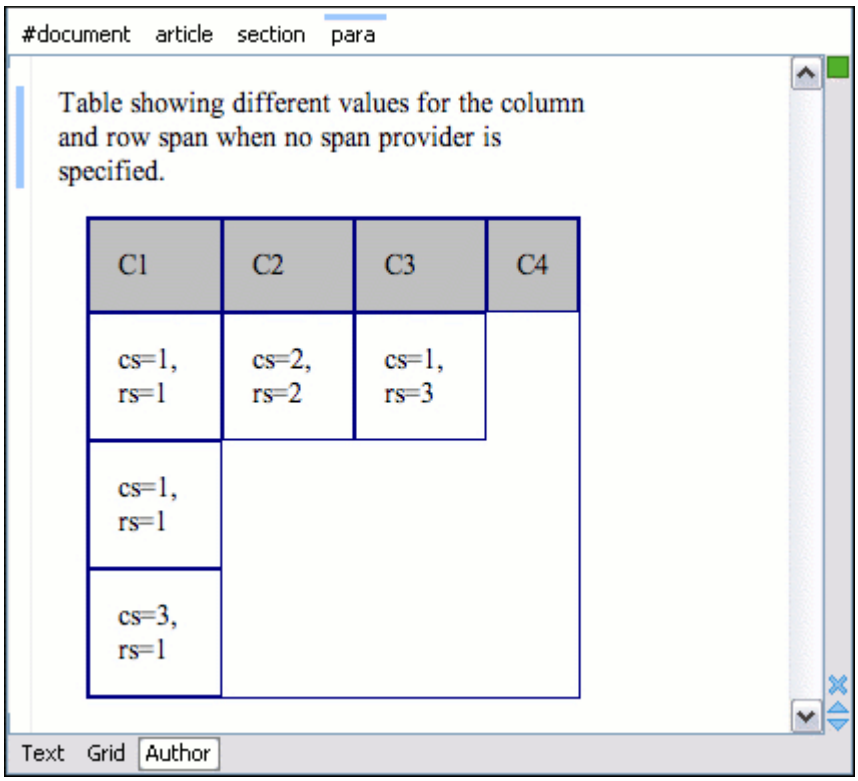
6. In the listing below, the XML document contains the table element:

```
<table>
    <header>
        <td>C1</td>
        <td>C2</td>
        <td>C3</td>
```

```
        <td>C4</td>
    </header>
    <tr>
        <td>cs=1, rs=1</td>
        <td column_span="2" row_span="2">cs=2, rs=2</td>
        <td row_span="3">cs=1, rs=3</td>
    </tr>
    <tr>
        <td>cs=1, rs=1</td>
    </tr>
    <tr>
        <td column_span="3">cs=3, rs=1</td>
    </tr>
</table>
```

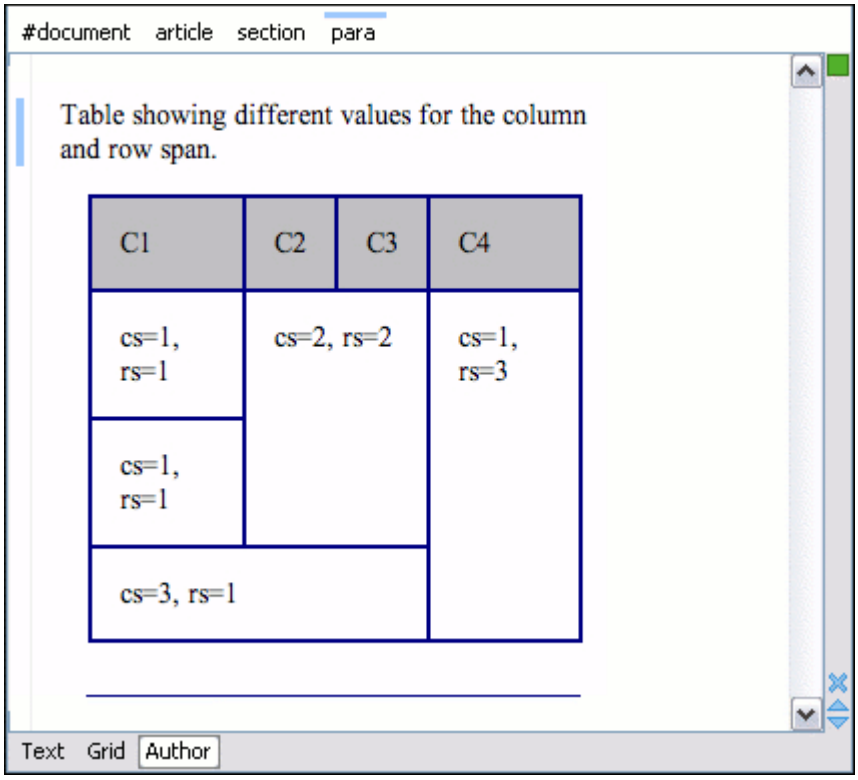
When no table cell span provider is specified, the table has the following layout:

Figure 607. Table layout when no cell span provider is specified



When the above implementation is configured, the table has the correct layout:

Figure 608. Cells spanning multiple rows and columns.



Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Configuring a Table Cell Row and Column Separator Provider

In a custom *framework (on page 3420)*, the `<table>` element has separators between rows. As explained in Configuring Tables *(on page 2366)*, you need to indicate a method to determine the way rows and columns are separated. If you use the `@rowsep` and `@colsep` cell element attributes, or your table is conforming to the CALS table model, Oxygen XML Editor can determine the cell separators. Even if there are no attributes that define the separators, you can still force a separator between rows by implementing a Java extension.

1. Create the class *simple.documentation.framework.TableCellSepProvider*. This class must implement the *ro.sync.ecss.extensions.api.AuthorTableCellSepProvider* interface.

```
import ro.sync.ecss.extensions.api.AuthorTableCellSepProvider;
import ro.sync.ecss.extensions.api.node.AuthorElement;

public class TableCellSepProvider implements AuthorTableCellSepProvider{
```

2. The *init* method takes the *ro.sync.ecss.extensions.api.node.AuthorElement* interface that represents the XML `<table>` element as its argument. If the separator information is implicit, it does not depend on the current table, so you leave this method empty. However, there are cases (such as the CALS table

model) when the cell separators are specified in the `<table>` element. In such cases, you should initialize your provider based on the given argument.

```
public void init(AuthorElement table) {
}
```

3. The *getColSep* method takes the table cell as its argument. The table layout engine will ask this *AuthorTableCellSepProvider* implementation if there is a column separator for each XML element from the table that was marked as cell in the CSS using the property `display:table-cell`. The following example returns **false**, meaning there will not be column separators.

```
/**
 * @return false - No column separator at the right of the cell.
 */
@Override
public boolean getColSep(AuthorElement cellElement, int columnIndex) {
  return false;
}
```

4. The row separators are determined in a similar manner. This time the example returns **true**, forcing a separator between the rows.

```
/**
 * @return true - A row separator below each cell.
 */
@Override
public boolean getRowSep(AuthorElement cellElement, int columnIndex) {
  return true;
}
```

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

5. In the example below, the XML document contains the table element:

```
<table>
     <header>
       <td>H1</td>
       <td>H2</td>
       <td>H3</td>
       <td>H4</td>
     </header>
     <tr>
       <td>C11</td>
```

```
      <td>C12</td>
      <td>C13</td>
      <td>C14</td>
    </tr>
    <tr>
      <td>C21</td>
      <td>C22</td>
      <td>C23</td>
      <td>C24</td>
    </tr>
    <tr>
      <td>C31</td>
      <td>C32</td>
      <td>C33</td>
      <td>C34</td>
    </tr>
  </table>
```

When the borders for the `<td>` element are removed from the CSS, the row separators become visible:

Figure 609. Row separators provided by the Java implementation.

H1	H2	H3	H4
C11	C12	C13	C14
C21	C22	C23	C24
C31	C32	C33	C34

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Customizing Attribute Value Editors

The *CustomAttributeValueEditor* extension point allows you customize the attribute value editing mechanisms in Oxygen XML Editor. It changes the **Browse** button found in the attribute editors to an **Edit** button. When a user clicks that **Edit** button, your custom attribute value editor will be presented.

The  **Edit** button can be accessed in the following attribute editors:

- The **Attributes** view in **Author** mode *(on page 638)* (when the **Expand** button is used to reveal an expanded panel).
- The **Attributes** view in **Text** mode *(on page 552)* (when the **Expand** button is used to reveal an expanded panel).
- The **In-place Attributes Editor** *(on page 640)* when invoked in **Author** mode.
- The **In-place Attributes Editor** invoked in the **Outline** view *(on page 549)*.

How to Implement a *CustomAttributeValueEditor*

To implement your own *CustomAttributeValueEditor*, follow this procedure:

1. Extend the *ro.sync.ecss.extensions.api.CustomAttributeValueEditor* abstract class.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
   a. If you have configured an extensions bundle *(on page 2350)*, you can return the *CustomAttributeValueEditor* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.createCustomAttributeValueEditor()* method.
   b. Specify the *CustomAttributeValueEditor* in the **Author custom attribute value editor** individual extension in the **Extensions** tab *(on page 174)* of the **Document Type** configuration dialog box *(on page 147)* for your particular document type.

Example

The following example creates a very simple custom attribute value editor:

```
/**
 * A custom attribute value editor.
 */
public class MyCustomAttributeValueEditor extends CustomAttributeValueEditor {

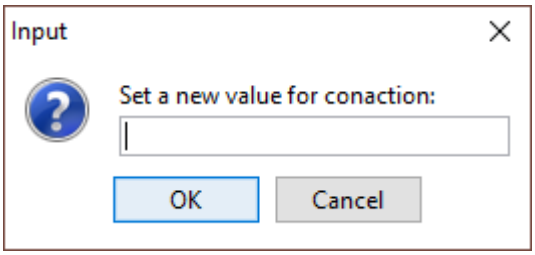
  /**
   * @see ro.sync.ecss.extensions.api.Extension#getDescription()
   */
  @Override
  public String getDescription() {
    return "My custom attribute value editor";
  }

  /**
   * @see ro.sync.ecss.extensions.api.CustomAttributeValueEditor#getAttributeValue
            (ro.sync.ecss.extensions.api.EditedAttribute, java.lang.Object)
   */
```

```
  @Override
  public String getAttributeValue(EditedAttribute attribute, Object parentComponent)
      throws CancelledByUserException {
    // Show an input dialog for collecting the new value
    return JOptionPane.showInputDialog
                    ("Set a new value for " + attribute.getAttributeQName() + ":");
  }

  /**
   * @see ro.sync.ecss.extensions.api.CustomAttributeValueEditor#shouldHandleAttribute
                    (ro.sync.ecss.extensions.api.EditedAttribute)
   */
  @Override
  public boolean shouldHandleAttribute(EditedAttribute attribute) {
    // Handle all attributes
    return true;
  }
}
```

Example result: If a user were to click the  **Edit** button in any of the attribute editors, the following dialog box would be displayed that allows the user to insert a value for the particular attribute:



Customizing the CSS Styles Filter

You can modify the CSS styles for each *ro.sync.ecss.extensions.api.node.AuthorNode* rendered in the **Author** mode using an implementation of *ro.sync.ecss.extensions.api.StylesFilter*. You can implement the various callbacks of the interface either by returning the default value given by Oxygen XML Editor or by contributing to the value. The received styles *ro.sync.ecss.css.Styles* can be processed and values can be overwritten with your own. For example, you can override the `KEY_BACKGROUND_COLOR` style to return your own implementation of *ro.sync.exml.view.graphics.Color* or override the `KEY_FONT` style to return your own implementation of *ro.sync.exml.view.graphics.Font*.

For instance, in this simple document example, the filter can change the value of the `KEY_FONT` property for the `<table>` element:

```
package simple.documentation.framework;
```

```
import ro.sync.ecss.css.Styles;
import ro.sync.ecss.extensions.api.StylesFilter;
import ro.sync.ecss.extensions.api.node.AuthorNode;
import ro.sync.exml.view.graphics.Font;

public class SDFStylesFilter implements StylesFilter {

    public Styles filter(Styles styles, AuthorNode authorNode) {
        if (AuthorNode.NODE_TYPE_ELEMENT == authorNode.getType()
          && "table".equals(authorNode.getName())) {
          styles.setProperty(Styles.KEY_FONT, new Font(null, Font.BOLD, 12));
        }
        return styles;
    }
}
```

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Customizing Elements that Wrap Profiled Content

For each *framework (on page 3420)* (document type), you can configure the phrase-type elements that wrap the profiled content by setting a custom *ro.sync.ecss.extensions.api.ProfilingConditionalTextProvider*. This configuration is set by default for DITA and DocBook *frameworks*.

Customizing the Link Target Reference Finder

The link target reference finder represents the support for finding references from links that indicate specific elements inside an XML document. This support will only be available if a schema is associated with the document type.

If you do not define a custom link target reference finder, the `DefaultElementLocatorProvider` implementation *(on page 2382)* will be used by default. The interface that should be implemented for a custom link target reference finder is `ro.sync.ecss.extensions.api.link.ElementLocatorProvider`. As an alternative, the `ro.sync.ecss.extensions.commons.DefaultElementLocatorProvider` implementation can also be extended.

The used `ElementLocatorProvider` will be queried for an `ElementLocator` when a link location must be determined (when a link is clicked). Then, to find the corresponding (linked) element, the obtained `ElementLocator` will be queried for each element from the document.

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Creating a Custom Link Target Reference Finder

If you need to create a custom link target reference finder you can do so by creating the class that will implement the `ro.sync.ecss.extensions.api.link.ElementLocatorProvider` interface. As an alternative, your class could extend `ro.sync.ecss.extensions.commons.DefaultElementLocatorProvider`, the default implementation.

Note:
The complete source code of the `ro.sync.ecss.extensions.commons.DefaultElementLocatorProvider`, `ro.sync.ecss.extensions.commons.IDElementLocator` or `ro.sync.ecss.extensions.commons.XPointerElementLocator` can be found in the **oxygen-sample-framework** project.

Default Link Target Reference Finder

The *DefaultElementLocatorProvider* implementation is used by default to find link target references. It offers support for the most common types of links:

- Links based on ID attribute values *(on page 2383)*.
- XPointer element() scheme *(on page 2384)*.

The method *getElementLocator* determines what *ElementLocator* should be used. In the default implementation, it checks if the link is an XPointer element() scheme. Otherwise, it assumes it is an ID. A non-null *IDTypeVerifier* will always be provided if a schema is associated with the document type.

The `link` string argument is the *anchor (on page 3417)* part of the of the URL that is composed from the value of the link property specified for the link element in the CSS.

```
public ElementLocator getElementLocator(IDTypeVerifier idVerifier,
                String link) {
  ElementLocator elementLocator = null;
  try {
    if(link.startsWith("element(")){
      // xpointer element() scheme
      elementLocator = new XPointerElementLocator(idVerifier, link);
    } else {
      // Locate link element by ID
      elementLocator = new IDElementLocator(idVerifier, link);
    }
```

```
  } catch (ElementLocatorException e) {
    logger.warn("Exception when create element locator for link: "
        + link + ". Cause: " + e, e);
  }
  return elementLocator;
}
```

ID Element Locator

The *IDElementLocator* is an implementation of the abstract class *ro.sync.ecss.extensions.api.link.ElementLocator* for links that use an **ID**.

The constructor only assigns field values and the method *endElement* is empty for this implementation.

The method *startElement* checks each of the element's attribute values and when one matches the link, it considers the element found if one of the following conditions is satisfied:

- The qualified name of the attribute is `xml:id`.
- The attribute type is ID.

The attribute type is checked with the help of the method *IDTypeVerifier.hasIDType*.

```
public boolean startElement(String uri, String localName,
        String name, Attr[] atts) {
  boolean elementFound = false;
  for (int i = 0; i < atts.length; i++) {
    if (link.equals(atts[i].getValue())) {
      if("xml:id".equals(atts[i].getQName())) {
        // xml:id attribute
        elementFound = true;
      } else {
        // check if attribute has ID type
        String attrLocalName =
          ExtensionUtil.getLocalName(atts[i].getQName());
        String attrUri = atts[i].getNamespace();
        if (idVerifier.hasIDType(localName, uri, attrLocalName, attrUri)) {
          elementFound = true;
        }
      }
    }
  }

  return elementFound;
}
```

XPointer Element Locator

XPointerElementLocator is an implementation of the abstract class *ro.sync.ecss.extensions.api.link.ElementLocator* for links that have one of the following XPointer element() scheme patterns:

element (*elementID*)

Locate the element with the specified ID.

element (*/1/2/3*)

A child sequence appearing alone identifies an element by means of stepwise navigation, which is directed by a sequence of integers separated by slashes (/). Each integer n locates the nth child element of the previously located element.

element (*elementID/3/4*)

A child sequence appearing after a *NCName* identifies an element by means of stepwise navigation, starting from the element located by the given name.

The constructor separates the ID/integers, which are delimited by slashes(/) into a sequence of identifiers (an XPointer path). It will also check that the link has one of the supported patterns of the XPointer element() scheme.

```
public XPointerElementLocator(IDTypeVerifier idVerifier, String link)
                      throws ElementLocatorException {
  super(link);
  this.idVerifier = idVerifier;

  link = link.substring("element(".length(), link.length() - 1);

  StringTokenizer stringTokenizer = new StringTokenizer(link, "/", false);
  xpointerPath = new String[stringTokenizer.countTokens()];
  int i = 0;
  while (stringTokenizer.hasMoreTokens()) {
    xpointerPath[i] = stringTokenizer.nextToken();
    boolean invalidFormat = false;

    // Empty xpointer component is not supported
    if(xpointerPath[i].length() == 0){
      invalidFormat = true;
    }

    if(i > 0){
      try {
        Integer.parseInt(xpointerPath[i]);
```

```
      } catch (NumberFormatException e) {
        invalidFormat = true;
      }
    }

    if(invalidFormat){
      throw new ElementLocatorException(
        "Only the element() scheme is supported when locating XPointer links."
        + "Supported formats: element(elementID), element(/1/2/3),
              element(elemID/2/3/4).");
    }
    i++;
  }

  if(Character.isDigit(xpointerPath[0].charAt(0))){
    // This is the case when xpointer have the following pattern /1/5/7
    xpointerPathDepth = xpointerPath.length;
  } else {
    // This is the case when xpointer starts with an element ID
    xpointerPathDepth = -1;
    startWithElementID  = true;
  }
}
```

The method *startElement* will be invoked at the beginning of every element in the XML document(even when the element is empty). The arguments it takes are

uri

The namespace URI, or the empty string if the element has no namespace URI or if namespace processing is disabled.

localName

Local name of the element.

qName

Qualified name of the element.

atts

Attributes attached to the element. If there are no attributes, this argument will be empty.

The method returns `true` if the processed element is found to be the one indicated by the link.

The *XPointerElementLocator* implementation of the *startElement* will update the depth of the current element and keep the index of the element in its parent. If the `xpointerPath` starts with an element ID then the current

element ID is verified to match the specified ID. If this is the case the depth of the XPointer is updated taking into account the depth of the current element.

If the XPointer path depth is the same as the current element depth then the kept indices of the current element path are compared to the indices in the XPointer path. If all of them match then the element has been found.

```
public boolean startElement(String uri, String localName,
        String name, Attr[] atts) {
  boolean linkLocated = false;
  // Increase current element document depth
  startElementDepth ++;

  if (endElementDepth != startElementDepth) {
    // The current element is the first child of the parent
    currentElementIndexStack.push(new Integer(1));
  } else {
    // Another element in the parent element
    currentElementIndexStack.push(new Integer(lastIndexInParent + 1));
  }

  if (startWithElementID) {
    // This the case when xpointer path starts with an element ID.
    String xpointerElement = xpointerPath[0];
    for (int i = 0; i < atts.length; i++) {
      if(xpointerElement.equals(atts[i].getValue())){
        if(idVerifier.hasIDType(
            localName, uri, atts[i].getQName(), atts[i].getNamespace())){
          xpointerPathDepth = startElementDepth + xpointerPath.length - 1;
          break;
        }
      }
    }
  }

  if (xpointerPathDepth == startElementDepth){
    // check if xpointer path matches with the current element path
    linkLocated = true;
    try {
      int xpointerIdx = xpointerPath.length - 1;
      int stackIdx = currentElementIndexStack.size() - 1;
      int stopIdx = startWithElementID ? 1 : 0;
      while (xpointerIdx >= stopIdx && stackIdx >= 0) {
```

```
        int xpointerIndex = Integer.parseInt(xpointerPath[xpointerIdx]);
        int currentElementIndex =
          ((Integer)currentElementIndexStack.get(stackIdx)).intValue();
        if(xpointerIndex != currentElementIndex) {
          linkLocated = false;
          break;
        }

        xpointerIdx--;
        stackIdx--;
      }

    } catch (NumberFormatException e) {
      logger.warn(e,e);
    }
  }
  return linkLocated;
}
```

The method *endElement* will be invoked at the end of every element in the XML document (even when the element is empty).

The *XPointerElementLocator* implementation of the *endElement* updates the depth of the current element path and the index of the element in its parent.

```
public void endElement(String uri, String localName, String name) {
  endElementDepth = startElementDepth;
  startElementDepth --;
  lastIndexInParent = ((Integer)currentElementIndexStack.pop()).intValue();
}
```

Customizing XML Node Rendering

You can use this API extension to customize the way an XML node is rendered in the **Outline** view *(on page 549)* in **Author** mode, breadcrumb navigation bar *(on page 612)* in **Author** mode, **Outline** view *(on page 549)* in **Text** mode, *Content Completion Assistant (on page 3418)* window, or **DITA Maps Manager** view *(on page 3073)*.

Note:
Oxygen XML Editor uses *XMLNodeRendererCustomizer* implementations for the following *frameworks (on page 3420)*: DITA, DITA Map, DocBook 4, DocBook 5, TEI, XHTML, XSLT, and XML Schema.

There are two methods to provide an implementation of *ro.sync.exml.workspace.api.node.customizer.XMLNodeRendererCustomizer*:

- As a part of a bundle, returning it from the *createXMLNodeCustomizer()* method of the *ExtensionsBundle* associated with your document type in the **Document type** configuration dialog box *(on page 147)* (**Extensions bundle** field in the **Extensions** tab).
- As an individual extension, associated with your document type in the **Document type** configuration dialog box *(on page 147)* (**XML node renderer customizer** field in the **Individual extensions** section of the **Extensions** tab).

Support for Retina/HiDPI Displays

To support Retina or HiDPI displays, the icons provided by the *XMLNodeRendererCustomizer* should be backed up by a copy of larger size using the proper Retina/HiDPI naming convention *(on page 735)*.

For example, for the `<title>` element, if the *XMLNodeRendererCustomizer* returns the path `${framework}/images/myImg.png`, then to support Retina images with a scaling factor of 2, an extra file (`myImg@2x.png`)should be added to the same images directory (`${framework}/images/myImg@2x.png`). If the higher resolution icon (the *@2x* file) does not exist, the *normal* icon is scaled and used instead.

For more information about using Retina/HiDPI images, refer to the Using Retina/HiDPI Images in Author Mode *(on page 734)* section.

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Customizing the Rendering of Elements *(on page 2325)*
Using Retina/HiDPI Icons for the Actions from a Framework *(on page 2299)*

Customizing Author Operations

Oxygen XML Editor **Author** mode has a built-in set of operations covering the insertion of text and XML fragments (see the Author Default Operations *(on page 2269)*) and the execution of XPath expressions on the current document edited in **Author** mode. However, there are situations where you need to extend this set. The following examples are just a few of the possible situations:

- You need to enter an element whose attributes will be edited by the user through a graphical user interface.
- The user must send selected element content (or the whole document) to a+ server for some kind of processing.

- Content authors need to extract pieces of information from a server and insert it directly into the edited XML document.
- You need to apply an XPath expression on the current document and process the nodes of the resulting node set.

To extend the Oxygen XML Editor **Author** mode functionality through Java, you will need the Oxygen SDK available on the Oxygen XML Editor website. It includes the source code of the **Author** mode operations in the built-in document types and the full documentation (in Javadoc format) of the public API available for **Author** mode custom actions.

The subsequent Java examples make use of AWT classes. If you are developing extensions for the Oxygen XML Editor XML Editor plugin for Eclipse, you will have to use their SWT counterparts.

Attention:
Make sure the Java classes of your custom **Author** mode operations are compiled with the same Java version used by Oxygen XML Editor. Otherwise, the classes may not be loaded by the Java virtual machine. For example, if you run a version of Oxygen XML Editor with a Java 11 virtual machine but the Java classes of your custom **Author** mode operations are compiled with a Java 12 or later virtual machine, then the custom operations cannot be loaded and used by the Java 11 virtual machine.

Important:
From a legal standpoint, you can freely develop and share extensions using the **Oxygen SDK** ONLY if you have a legal, active license to use Oxygen XML Editor and ONLY if such extensions are used from inside Oxygen XML Editor. To use such extensions outside of Oxygen XML Editor (for example, a 3rd-party application that has Oxygen XML Editor built in to it), an additional license must be purchased to use the SDK according the **Oxygen XML SDK Licensing Policy** .

Related Information:
https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/AuthorOperation.html
Extending Oxygen With the SDK *(on page 2530)*

Example 1 - Simple Use of a Dialog Box from an Author Mode Operation

In this example, functionality is added for inserting images in a custom *framework (on page 3420)*. The images are represented by the `<image>` element. The location of the image file is represented by the value of the `@href` attribute. In the Java implementation, a dialog box will be displayed with a text field where the user can enter a full URL or browse for a local file.

1. Set up a sample project following this set of instructions. The *framework* project is **oxygen-sample-framework**.
2. Modify the *simple.documentation.framework.InsertImageOperation* class that implements the *ro.sync.ecss.extensions.api.AuthorOperation* interface. This interface defines three methods: *doOperation*, *getArguments* and *getDescription*

   A short description of these methods follows:

   - The *doOperation* method is invoked when the action is performed either by pressing the toolbar button, by selecting the menu item or by pressing the shortcut key. The arguments taken by this method can be one of the following combinations:
     - An object of type *ro.sync.ecss.extensions.api.AuthorAccess* and a map.
     - Argument names and values.
   - The *getArguments* method is used by Oxygen XML Editor when the action is configured. It returns the list of arguments (name and type) that are accepted by the operation.
   - The *getDescription* method is used by Oxygen XML Editor when the operation is configured. It returns a description of the operation.

   Example:

   Here is the implementation of these three methods:

```
/**
 * Performs the operation.
 */
public void doOperation(
           AuthorAccess authorAccess,
           ArgumentsMap arguments)
    throws IllegalArgumentException,
              AuthorOperationException {

JFrame oxygenFrame = (JFrame) authorAccess.getWorkspaceAccess().getParentFrame()
;
    String href = displayURLDialog(oxygenFrame);
    if (href.length() != 0) {
       // Creates the image XML fragment.
       String imageFragment =
         "<image xmlns='http://www.oxygenxml.com/sample/documentation' href='"
          + href + "'/>";

       // Inserts this fragment at the cursor position.
       int caretPosition = authorAccess.getEditorAccess().getCaretOffset();
       authorAccess.getDocumentController().insertXMLFragment
(imageFragment, caretPosition);
    }
```

```
}

/**
 * Has no arguments.
 *
 * @return null.
 */
public ArgumentDescriptor[] getArguments() {
  return null;
}

/**
 * @return A description of the operation.
 */
public String getDescription() {
  return "Inserts an image element. Asks the user for a URL reference.";
}
```

Note:

The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Important:

Make sure you always specify the namespace of the inserted fragments.

```
<image xmlns='http://www.oxygenxml.com/sample/documentation'
  href='path/to/image.png'/>
```

3. Package the compiled class into a *JAR (on page 3420)* file. An example of an Ant script that packages the `classes` folder content into a *JAR* archive named `sdf.jar` is listed below:

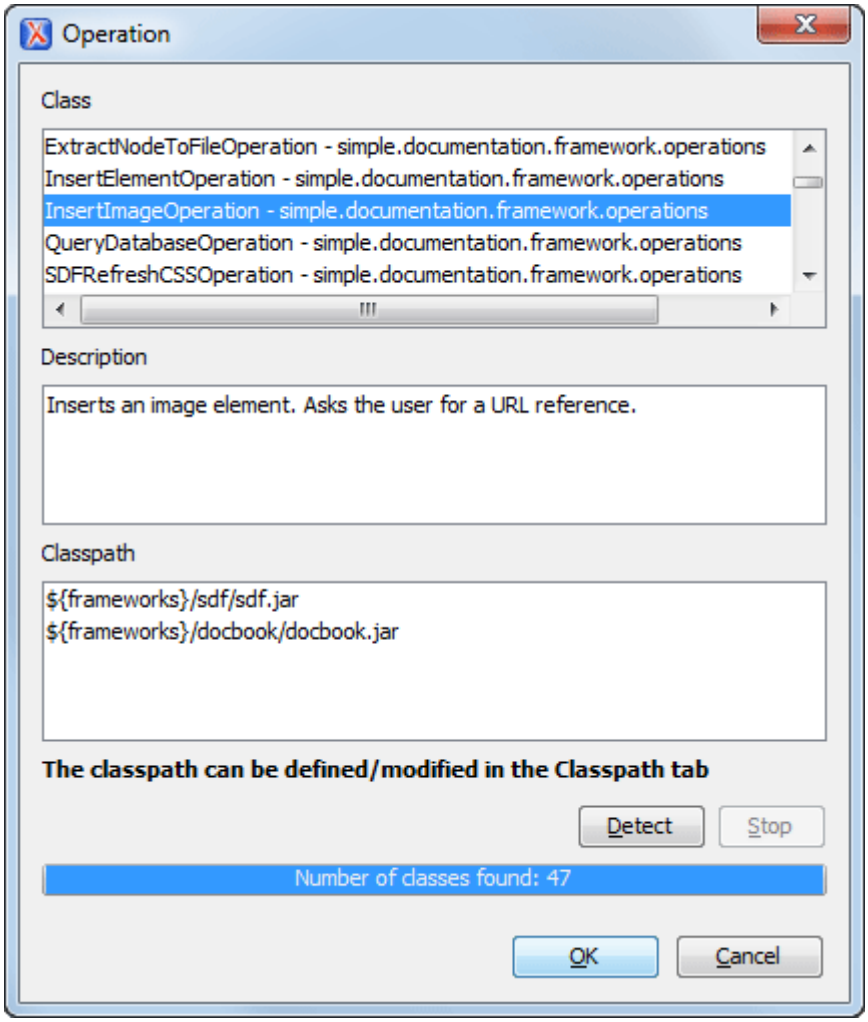
```
<?xml version="1.0" encoding="UTF-8"?>
<project name="project" default="dist">
    <target name="dist">
      <jar destfile="sdf.jar" basedir="classes">
        <fileset dir="classes">
          <include name="**/*"/>
        </fileset>
      </jar>
    </target>
</project>
```

4. Copy the `sdf.jar` file into your custom *framework* directory (*`[OXYGEN_INSTALL_DIR]`*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).
5. Add the `sdf.jar` to the class path. To do this, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, select **SDF**, and click the **Edit** button.
6. Select the **Classpath** tab in the lower part of the **Document Type** configuration dialog box *(on page 147)* and click the **Add** button. In the displayed dialog box, enter the location of the *JAR* file, relative to the Oxygen XML Editor `frameworks` folder.
7. Next, create the action that will use the defined operation. Go to the **Actions** subtab. Copy the icon files for the menu item and for the toolbar in your custom *framework* directory (*`[OXYGEN_INSTALL_DIR]`*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).
8. Define the action's properties:
   - Set **ID** to **insert_image**.
   - Set **Name** to **Insert image**.
   - Set **Menu access key** to letter **i**.
   - Set **Toolbar action** to **${framework}/toolbarImage.png**.
   - Set **Menu icon** to **${framework}/menuImage.png**.
   - Set **Shortcut key** to **Ctrl (Meta on macOS)+Shift+i**.
9. Next, set up the operation. You want to add images only if the current element is a `<section>`, `<book>` or `<article>`.
   - Set the value of **XPath expression** to

     ```
     local-name()='section' or local-name()='book'
      or local-name()='article'
     ```

   - Set the **Invoke operation** field to *simple.documentation.framework.InsertImageOperation*.

Figure 610. Selecting the Operation



10. Add the action to the toolbar, using the **Toolbar** panel.

To test the action, open or create an XML file and place the cursor at a valid location. Then click the button associated with the action from the toolbar. In the dialog box, select an image URL and click **OK**. The image is inserted into the document.

Example 2 - Operations with Arguments - Report from Database Operation

In this example, an operation is created that connects to a relational database and executes an SQL statement. The result should be inserted in the edited XML document as a table. To make the operation fully configurable, it will have arguments for the *database connection string*, the *user name*, the *password* and the *SQL expression*.

1. Set up a sample project following this set of instructions. The *framework* project is **oxygen-sample-framework**.
2. Create the class `simple.documentation.framework.QueryDatabaseOperation`. This class must implement the *ro.sync.ecss.extensions.api.AuthorOperation* interface.

```
import ro.sync.ecss.extensions.api.ArgumentDescriptor;
import ro.sync.ecss.extensions.api.ArgumentsMap;
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.AuthorOperation;
import ro.sync.ecss.extensions.api.AuthorOperationException;

public class QueryDatabaseOperation implements AuthorOperation{
```

3. Now define the operation's arguments. For each of them, you will use a `String` constant representing the argument name:

```
private static final String ARG_JDBC_DRIVER ="jdbc_driver";
private static final String ARG_USER ="user";
private static final String ARG_PASSWORD ="password";
private static final String ARG_SQL ="sql";
private static final String ARG_CONNECTION ="connection";
```

4. You must describe the argument name and type. To do this, implement the `getArguments` method that will return an array of argument descriptors:

```
public ArgumentDescriptor[] getArguments() {
  ArgumentDescriptor args[] = new ArgumentDescriptor[] {
    new ArgumentDescriptor(
      ARG_JDBC_DRIVER,
      ArgumentDescriptor.TYPE_STRING,
      "The name of the Java class that is the JDBC driver."),
    new ArgumentDescriptor(
      ARG_CONNECTION,
      ArgumentDescriptor.TYPE_STRING,
      "The database URL connection string."),
    new ArgumentDescriptor(
      ARG_USER,
      ArgumentDescriptor.TYPE_STRING,
      "The name of the database user."),
    new ArgumentDescriptor(
      ARG_PASSWORD,
      ArgumentDescriptor.TYPE_STRING,
      "The database password."),
   new ArgumentDescriptor(
     ARG_SQL,
     ArgumentDescriptor.TYPE_STRING,
     "The SQL statement to be executed.")
  };
```

```
  return args;
}
```

These names, types and descriptions will be listed in the **Arguments** table when the operation is configured.

5. When the operation is invoked, the implementation of the `doOperation` method extracts the arguments, forwards them to the method that connects to the database and generates the XML fragment. The XML fragment is then inserted at the cursor position.

```
public void doOperation(AuthorAccess authorAccess, ArgumentsMap map)
  throws IllegalArgumentException, AuthorOperationException {

  // Collects the arguments.
  String jdbcDriver = (String)map.getArgumentValue(ARG_JDBC_DRIVER);
  String connection = (String)map.getArgumentValue(ARG_CONNECTION);
  String user = (String)map.getArgumentValue(ARG_USER);
  String password = (String)map.getArgumentValue(ARG_PASSWORD);
  String sql = (String)map.getArgumentValue(ARG_SQL);

  int caretPosition = authorAccess.getCaretOffset();
  try {
    authorAccess.getDocumentController().insertXMLFragment(
      getFragment(jdbcDriver, connection, user, password, sql), caretPosition);
  } catch (SQLException e) {
    throw new AuthorOperationException(
      "The operation failed due to the following database error: "
      + e.getMessage(), e);
  } catch (ClassNotFoundException e) {
    throw new AuthorOperationException(
      "The JDBC database driver was not found. Tried to load ' "
      + jdbcDriver + "'", e);
  }
}
```

6. The `getFragment` method loads the JDBC driver, connects to the database and extracts the data. The result is a `<table>` element from the `http://www.oxygenxml.com/sample/documentation` namespace. The `<header>` element contains the names of the SQL columns. All the text from the XML fragment is escaped. This means that the '<' and '&' characters are replaced with the '<' and '&' character entities to ensure that the fragment is well-formed.

```
private String getFragment(String jdbcDriver, String connectionURL, String user,
  String password, String sql) throws SQLException, ClassNotFoundException {

    Properties pr = new Properties();
```

```
        pr.put("characterEncoding", "UTF8");
        pr.put("useUnicode", "TRUE");
        pr.put("user", user);
        pr.put("password", password);

        // Loads the database driver.
        Class.forName(jdbcDriver);
        // Opens the connection
        Connection connection = DriverManager.getConnection(connectionURL, pr);
        java.sql.Statement statement = connection.createStatement();
        ResultSet resultSet = statement.executeQuery(sql);

        StringBuffer fragmentBuffer = new StringBuffer();
        fragmentBuffer.append(
          "<table xmlns=" +
          "'http://www.oxygenxml.com/sample/documentation'>");

        //
        // Creates the table header.
        //
        fragmentBuffer.append("<header>");
        ResultSetMetaData metaData = resultSet.getMetaData();
        int columnCount = metaData.getColumnCount();
        for (int i = 1; i <= columnCount; i++) {
            fragmentBuffer.append("<td>");
            fragmentBuffer.append(xmlEscape(metaData.getColumnName(i)));
            fragmentBuffer.append("</td>");
        }
        fragmentBuffer.append("</header>");

        //
        // Creates the table content.
        //
        while (resultSet.next()) {
            fragmentBuffer.append("<tr>");
            for (int i = 1; i <= columnCount; i++) {
                fragmentBuffer.append("<td>");
                fragmentBuffer.append(xmlEscape(resultSet.getObject(i)));
                fragmentBuffer.append("</td>");
            }
            fragmentBuffer.append("</tr>");
        }
```

```
        fragmentBuffer.append("</table>");

        // Cleanup
        resultSet.close();
        statement.close();
        connection.close();
        return fragmentBuffer.toString();
    }
```

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

7. Package the compiled class into a *JAR (on page 3420)* file.
8. Copy the *JAR* file and the JDBC driver files into your custom *framework* directory (*[OXYGEN_INSTALL_DIR]*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).
9. Add the *JARS* to the class path. To do this, open the **Document Type Association** preferences page *(on page 145)*, select **SDF** and click the **Edit** button. Select the **Classpath** tab in the lower part of the **Document Type** configuration dialog box *(on page 147)* and click the **Add** button. In the displayed dialog box, enter the location of the *JAR* file, relative to the Oxygen XML Editor `frameworks` folder.
10. Go to the **Actions** subtab. The action properties are:
    - Set **ID** to **clients_report**.
    - Set **Name** to **Clients Report**.
    - Set **Menu access key** to letter **r**.
    - Set **Description** to **Connects to the database and collects the list of clients**.
    - Set **Toolbar icon** to **${framework}/TableDB20.png** (the `TableDB20.png` icon is stored in the `frameworks/sdf` folder).
    - Leave empty the **Menu icon**.
    - Set **shortcut key** to **Ctrl + Shift + C (Command + Shift + C on macOS)**.
11. The action will work only if the current element is a **section**. Set up the operation as follows:
    - Set **XPath expression** to:

      ```
      local-name()='section'
      ```

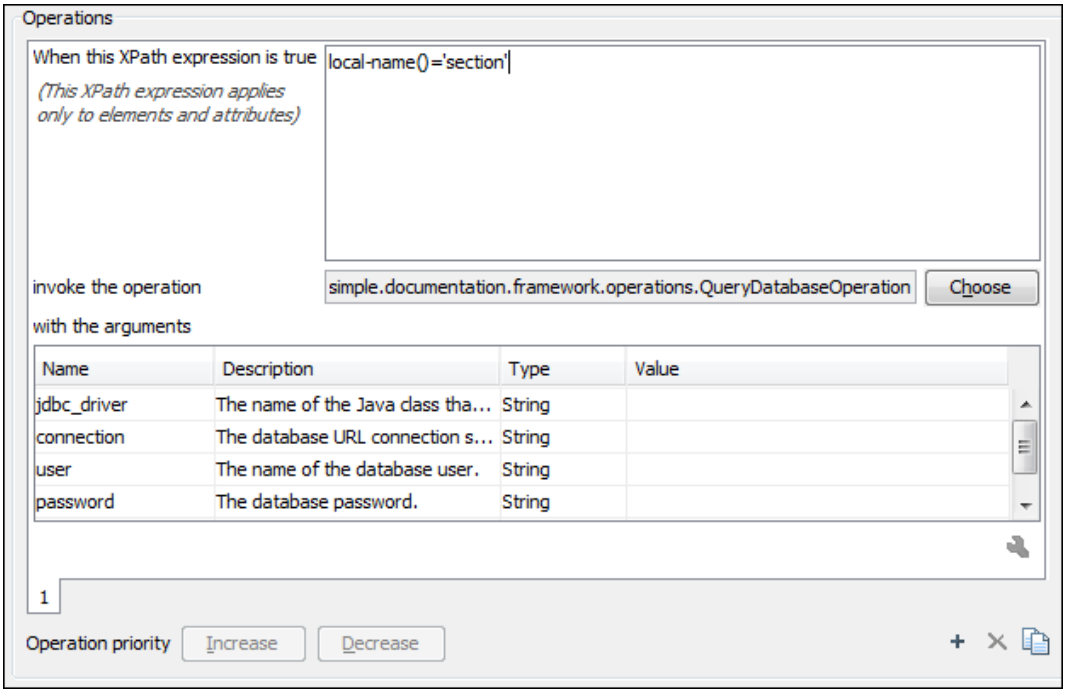
    - Use the Java operation defined earlier to set the **Invoke operation** field. Click the **Choose** button, then select `simple.documentation.framework.QueryDatabaseOperation`. Once selected, the list of arguments is displayed. In the figure below the first argument, *jdbc_driver*, represents the class name of the MySQL JDBC driver. The connection string has the URL syntax: *jdbc://<database_host>:<database_port>/<database_name>*.

The SQL expression used in the example follows, but it can be any valid SELECT expression that can be applied to the database:

```
SELECT userID, email FROM users
```

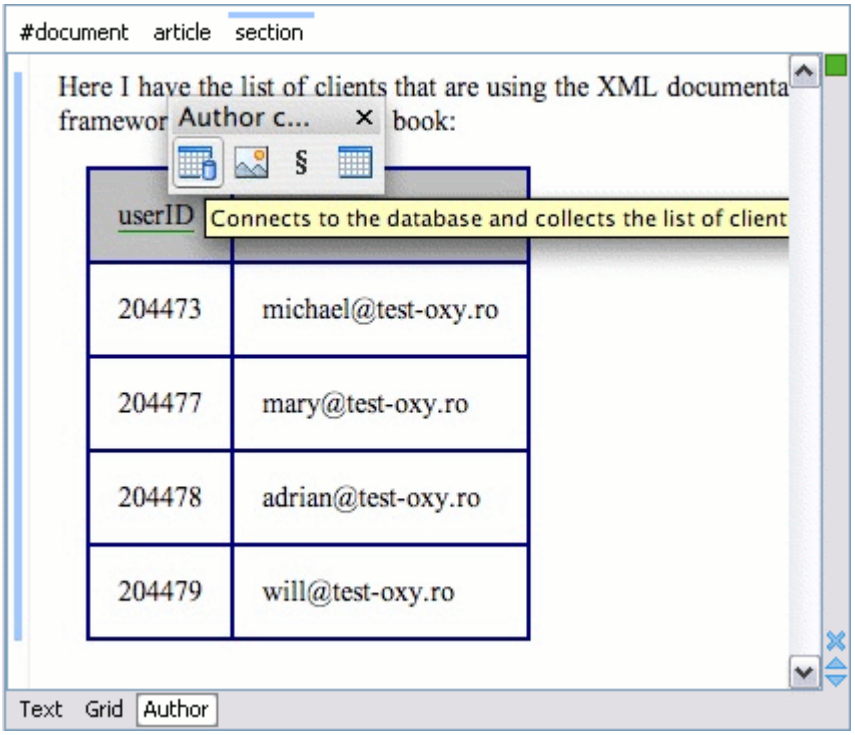
12. Add the action to the toolbar, using the **Toolbar** panel.

Figure 611. Java Operation Arguments Setup



To test the action, open or create an XML file and place the cursor at a valid location. Then click the  **Create Report** button from the toolbar. You can see below the toolbar with the action button and sample table inserted by the **Clients Report** action.

Figure 612. Table Content Extracted from the Database



Handling Author Mode Action Events

The *AuthorActionEventHandler* extension point allows you to handle certain **Author** mode actions in a special way. For example, a specific use-case would be if you want to insert new lines when you press **Enter** instead of it opening the *Content Completion Assistant (on page 3418)*.

How to Implement an *AuthorActionEventHandler*

To implement your own *AuthorActionEventHandler*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.AuthorActionEventHandler* interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
    a. If you have configured an extensions bundle *(on page 2350)*, you can return the *AuthorActionEventHandler* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.getAuthorActionEventHandler()* method.
    b. Specify the *AuthorActionEventHandler* in the **Author action event handler** individual extension in the **Extensions** tab *(on page 174)* of the **Document Type** configuration dialog box *(on page 147)* for your particular document type.

Example

The following example illustrates the use-case mentioned in the introduction, that is an implementation for inserting a new line when the user presses **Enter** in **Author** mode. It uses the *canHandleEvent* method to make sure the insertion will be performed in an element that will preserve the `new-line` character. Then the *handleEvent* method inserts the new line at the current cursor position.

```
public class CustomAuthorActionEventHandler implements AuthorActionEventHandler
{

 /**
  * @see ro.sync.ecss.extensions.api.AuthorActionEventHandler#canHandleEvent
(AuthorAccess, AuthorActionEventType)
  */
  @Override
  public boolean canHandleEvent(AuthorAccess authorAccess,
AuthorActionEventType type) {
    boolean canHandle = false;

    if (type == AuthorActionEventType.ENTER) {
      AuthorDocumentController documentController =
authorAccess.getDocumentController();
    int caretOffset = authorAccess.getEditorAccess().getCaretOffset();
    try {
      AuthorNode nodeAtOffset = documentController.getNodeAtOffset(caretOffset);
      if (nodeAtOffset instanceof AuthorElement) {
        AuthorElement elementAtOffset = (AuthorElement) nodeAtOffset;
        AttrValue xmlSpace = elementAtOffset.getAttribute("xml:space");
        if (xmlSpace != null && xmlSpace.getValue().equals("preserve")) {
          canHandle = true;
        }
      }
    } catch (BadLocationException ex) {
        if (logger.isDebugEnabled()) {
          logger.error(ex.getMessage(), ex);
        }
      }
    }

    return canHandle;
  }

 /**
  * @see ro.sync.ecss.extensions.api.AuthorActionEventHandler#handleEvent
(ro.sync.ecss.extensions.api.AuthorAccess,
ro.sync.ecss.extensions.api.AuthorActionEventHandler.AuthorActionEventType)
  */
  @Override
  public boolean handleEvent(AuthorAccess authorAccess,
```

```
AuthorActionEventType eventType) {
    int caretOffset = authorAccess.getEditorAccess().getCaretOffset();
    // Insert a new line
    authorAccess.getDocumentController().insertText(caretOffset, "\n");
    return true;
  }

  /**
   * @see ro.sync.ecss.extensions.api.Extension#getDescription()
   */
  @Override
  public String getDescription() {
    return "Insert a new line";
  }
}
```

Handling Schema-Aware Editing Events

The *AuthorSchemaAwareEditingHandlerAdapter* extension point allows you to handle certain **Author** mode actions in various ways. For example, implementing the `AuthorSchemaAwareEditingHandlerAdapter` makes it possible to handle events such as typing, the keyboard delete event at a given offset (using Delete or Backspace keys), delete element tags, delete selection, join elements, or paste fragment. It also makes it possible to improve solutions that are proposed by the paste mechanism in Oxygen XML Editor when pasting content (through the use of some specific methods *(on page 2402)*).

How to Implement an *AuthorSchemaAwareEditingHandlerAdapter*

For this handler to be called, the **Schema-Aware Editing** option *(on page 188)* must be set to **On** or **Custom** in the **Schema-Aware** preferences page *(on page 188)*. The handler can either resolve a specific case, let the default implementation take place, or reject the edit entirely by throwing an `InvalidEditException`.

To implement your own *AuthorSchemaAwareEditingHandlerAdapter*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.AuthorSchemaAwareEditingHandlerAdapter* extension.
2. To instruct Oxygen XML Editor to use this newly created implementation, configure an extensions bundle *(on page 2350)* and return the *AuthorSchemaAwareEditingHandlerAdapter* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.getAuthorSchemaAwareEditingHandlerAdapter()* method.

Example

Typing events can be handled using the *handleTyping* method. For example, the `AuthorSchemaAwareEditingHandler` checks if the schema is not a learned one, was loaded successfully, and if

the **Smart paste and drag and drop** option *(on page 189)* is selected. If these conditions are met, the event will be handled.

```
public class AuthorSchemaAwareEditingHandlerAdapter
              extends AuthorSchemaAwareEditingHandler {

/**
 * @see AuthorSchemaAwareEditingHandler#handleTyping
(int, char, ro.sync.ecss.extensions.api.AuthorAccess)
 */
public boolean handleTyping(int offset, char ch, AuthorAccess authorAccess)
throws InvalidEditException {
  boolean handleTyping = false;
  AuthorSchemaManager authorSchemaManager =
authorAccess.getDocumentController().getAuthorSchemaManager();
  if (!authorSchemaManager.isLearnSchema() &&
      !authorSchemaManager.hasLoadingErrors() &&
      authorSchemaManager.getAuthorSchemaAwareOptions().isEnableSmartTyping()) {
    try {
      AuthorDocumentFragment characterFragment =
authorAccess.getDocumentController().createNewDocumentTextFragment
(String.valueOf(ch));
      handleTyping = handleInsertionEvent
(offset, new AuthorDocumentFragment[] {characterFragment}, authorAccess);
    } catch (AuthorOperationException e) {
      throw new InvalidEditException
(e.getMessage(), "Invalid typing event: " + e.getMessage(), e, false);
    }
  }
  return handleTyping;
}
```

Note:
The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Methods for Improving the Paste Mechanism

getAncestorDetectionOptions

When pasting content in **Author** mode, if the result causes the document to become invalid, Oxygen XML Editor will propose solutions to make it valid. As a possible solution, Oxygen XML Editor might surround the pasted content in a sequence of ancestor elements. This

getAncestorDetectionOptions method allows you to choose which parent elements might be a possible solution.

canBeReplaced

Allows you to improve solutions that might be proposed by the paste mechanism when pasting content in Oxygen XML Editor. For example, when pasting an element inside an empty element with the same name, this *canBeReplaced* method allows Oxygen XML Editor to replace the empty node rather than pasting it after or before the empty node. The callback could also reject this behavior if, for instance, the replacement node contains attributes.

AuthorDocumentFragment Class

Handling When URLs or XHTML Fragments are Dropped or Pasted in Author Mode

The ***AuthorExternalObjectInsertionHandler*** extension can be used to configure how URLs or XHTML fragments from external applications are handled when they are dropped or pasted in **Author** mode.

How to Implement an *AuthorExternalObjectInsertionHandler*

To implement your own *AuthorExternalObjectInsertionHandler*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.AuthorExternalObjectInsertionHandler* interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
    a. If your framework is an extension of DITA, DocBook, TEI, or XHTML, you can specify the *AuthorExternalObjectInsertionHandler* in the **Author extern object Insertion handler** individual extension in the **Extensions** tab *(on page 174)* of the **Document Type** configuration dialog box *(on page 147)* for your particular document type.
    b. Otherwise, you can configure an extensions bundle *(on page 2350)*, then return the *AuthorExternalObjectInsertionHandler* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.createAuthorExternalObjectInsertionHandler()* method.
3. You can use a stylesheet to convert the pasted XHTML to your own XML vocabulary by overwriting the following method:

    ro.sync.ecss.extensions.api.AuthorExternalObjectInsertionHandler.getImporterStylesheetFileName(AuthorAccess)

    and return the file name of the stylesheet that will be applied. The path to the importer stylesheet must also be added in the **Classpath** tab *(on page 152)* in the **Document Type** configuration dialog box *(on page 147)* for your particular document type.

Example

The following example illustrates an implementation for the DITA framework:

```
  /**
   * @see ro.sync.ecss.extensions.api.ExtensionsBundle#
createExternalObjectInsertionHandler()
   */
  @Override
  public AuthorExternalObjectInsertionHandler createExternalObjectInsertionHandler() {
    return new DITAExternalObjectInsertionHandler();
  }
```

```
  /**
   * @see ro.sync.ecss.extensions.api.AuthorExternalObjectInsertionHandler#
getImporterStylesheetFileName(ro.sync.ecss.extensions.api.AuthorAccess)
   */
  @Override
  protected String getImporterStylesheetFileName(AuthorAccess authorAccess) {
    return "xhtml2ditaDriver.xsl";
  }
```

Tip:
For XHTML fragments, there is another method that you could use to configure how they are handled when they are pasted in **Author** mode. For more information, see Customizing Smart Paste Support *(on page 2306)*.

Presenting an Edit Properties Dialog Box for Actions in Author Mode

The *EditPropertiesHandler* extension point allows you to present a specialized dialog box when the action of double-clicking an element tag is intercepted in **Author** mode. For example, you could use it to present a dialog box that allows the user to editing the properties of an image.

How to Implement an *EditPropertiesHandler*

To implement your own *EditPropertiesHandler*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.EditPropertiesHandler* interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:

a. If you have configured an extensions bundle *(on page 2350)*, you can return the *EditPropertiesHandler* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.createEditPropertiesHandler()* method.
b. Specify the *EditPropertiesHandler* in the **Author edit properties handler** individual extension in the **Extensions** tab *(on page 174)* of the **Document Type** configuration dialog box *(on page 147)* for your particular document type.

Example

The following example illustrates an implementation for presenting a simple properties editing dialog box when a user double-clicks an `<image>` tag in **Author** mode (with tags displayed from the **Tags display mode** drop-down menu):

```
public class CustomEditPropertiesHandler implements EditPropertiesHandler {

  /**
   * @see ro.sync.ecss.extensions.api.Extension#getDescription()
   */
  @Override
  public String getDescription() {
    return "Sample implementation that handles properties for a table element.";
  }

  /**
   * @see ro.sync.ecss.extensions.api.EditPropertiesHandler#canEditProperties
(ro.sync.ecss.extensions.api.node.AuthorNode)
   */
  @Override
  public boolean canEditProperties(AuthorNode authorNode) {
    // If this node is an image element we can edit its properties.
    return "image".equals(authorNode.getDisplayName());
  }

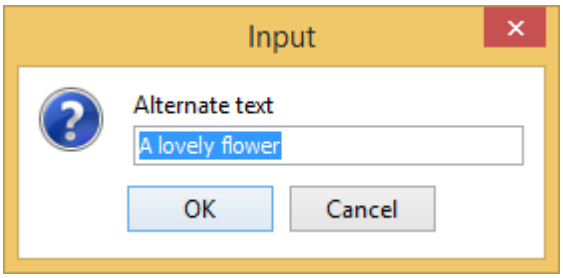
  /**
   * @see ro.sync.ecss.extensions.api.EditPropertiesHandler#editProperties
(ro.sync.ecss.extensions.api.node.AuthorNode,
 ro.sync.ecss.extensions.api.AuthorAccess)
   */
  @Override
  public void editProperties(AuthorNode authorNode, AuthorAccess authorAccess) {
    // If we receive this call then it surely an image.
    AuthorElement imageElement = (AuthorElement) authorNode;
    String currentValue = "";
    AttrValue altValue = imageElement.getAttribute("alt");
```

```
    if (altValue != null) {
      currentValue = altValue.getValue();
    }
    String newValue = JOptionPane.showInputDialog(
        (Component) authorAccess.getWorkspaceAccess().getParentFrame(),
        "Alternate text",
        currentValue);

    if (newValue != null) {
      authorAccess.getDocumentController().setAttribute
("alt", new AttrValue(newValue), imageElement);
    }
  }
}
```

Example result: If a user were to double-click an `<image>` tag icon (

) in **Author** mode, the following dialog box would be displayed that allows the user to edit the *alternate text* property for the image:



Sharing a Framework

You can create a custom *framework* by extending a built-in document type *(on page 2248)* (such as DITA or DocBook) using the **Document Type Association** preferences page *(on page 145)*, make modifications to it, and then share the extension with your team.

Sharing the Extended Framework

There are several ways that you can share the extended custom *framework (on page 2248)* with others:

- Distribute the extended *framework* along with a project by following these steps:
    1. In a location where you have full write access, create a folder for your project.
    2. Go to the **Project** view *(on page 413)* and create a project. Save it in the folder you created in step 1.
    3. Create a custom framework by extending an existing one *(on page 2248)*, if you have not already done so, and copy the custom framework directory to the folder you created in step 1. Make sure your custom framework directory includes any resources that are referenced in your framework (CSS files, new document templates, schemas used for validation, catalogs, etc.).

4. Go to **Options > Preferences > Document Type Association > Locations** *(on page 147)* and select **Project Options** *(on page 3423)* at the bottom of the page.
5. In the **Additional frameworks directories** list, add an entry using the **${pd}** editor variable *(on page 340)* like this: `${pd}/custom_frameworks`.
6. You can then share the new project directory with other users. For example, you can commit it to your version control system and have them update their working copy. When they open the customized project file in their **Project** view *(on page 413)*, the new *framework* becomes available in the list of document types.

- Pack and deploy the extended framework as an add-on *(on page 2407)*.
- Distribute the directory of the extended *framework (on page 2248)* to the other members of your team. They will simply copy that directory to their `/frameworks` directory. The new *framework* will be available in their list of document types when Oxygen XML Editor starts.

To test the extended *framework*, the other members of your team can check the list of document types in the **Document Type Association** preferences page *(on page 145)* to see if the *framework* is present and if it appears before the built-in *frameworks* (meaning that it has higher priority).

Packing and Deploying Frameworks as Add-ons

In Oxygen XML Editor, custom *framework (on page 3420)* can be packed and deployed as an *add-on*.

Packing a Framework as an Add-on

This procedure is suitable for developers who want a better control over the *add-on (on page 3422)* package or those who want to automate some of the steps:

1. Pack the full custom *framework (on page 2248)* (or an extension of a framework) as a ZIP file or a *Java Archive (on page 3420)*. Note that you should pack the entire root directory not just its contents.
2. **[Optional]** If you created a *Java Archive* at the previous step, digitally sign the package. You will need a certificate signed by a trusted authority. To sign the *JAR*, you can either use the *jarsigner* command-line tool inside Oracle's Java Development Kit (`[JDK_DIR]/bin/jarsigner.exe`) or if you are working with *Apache Ant (on page 3417)*, you can use the *signjar* task (a front for the *jarsigner* command-line tool). The benefit of having a signed add-on is that you can verify the integrity of the add-on issuer. If you do not have such a certificate, you can generate one yourself using the *keytool* command-line utility.

   > **Note:**
   > This approach is recommended for tests since anyone can create a self-signed certificate.

3. Create a descriptor file. You can use a template that Oxygen XML Editor provides by going to **File > New** and selecting the **Oxygen add-ons update site** template. The products the add-on is compatible with can be specified in the template. Once deployed, this descriptor file is referenced as *update site*.

Deploying an Add-on

To deploy an add-on, copy the `ZIP` or *Java Archive (on page 3420)* file and the descriptor file to an HTTP server. The URL to this location serves as the *Update Site URL*.

Basic Framework Customization Tutorial

This section contains topics meant to provide a general tutorial for customizing a *framework (on page 3420)*. It includes information about creating a basic document type association, some basic customizations, testing the configuration, packaging and deploying the custom framework, and more.

Tip:
A sample framework customization package is available that you can dabble with and use to help you get started. It can be downloaded from: https://www.oxygenxml.com/maven/com/oxygenxml/samples/oxygen-sample-framework/24.0.0.0/oxygen-sample-framework-24.0.0.0-package.zip. The package includes a sample CSS file, XSL file, schema files, document templates, an XML catalog file, custom icons, and other resources.

Framework Customization Overview

The most important elements of a document type customization are represented by an XML Schema to define the XML structure, the CSS to render the information and the XML instance template that links the first two together.

XML Grammar

To provide as-you-type validation and to compute valid insertion proposals, Oxygen XML Editor needs an XML grammar (XML Schema, DTD, or Relax NG) associated to the XML. The grammar specifies how the internal structure of the XML is defined. For information about associating a schema and how Oxygen XML Editor detects the schema, see Associating a Schema to XML Documents *(on page 827)*.

Consider a use-case where several users are testing a system and must send report results to a content management system. The customization should provide a visual editor for this type of document. The following XML Schema, `test_report.xsd` defines a report with results of a testing session. The report consists of a title, few lines describing the test suite that was run, and a list of test results (each with a name and a boolean value indicating if the test passed or failed).

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">
    <xs:element name="report">
        <xs:complexType>
```

```
            <xs:sequence>
                <xs:element ref="title"/>
                <xs:element ref="description"/>
                <xs:element ref="results"/>
            </xs:sequence>
        </xs:complexType>
    </xs:element>
    <xs:element name="title" type="xs:string"/>
    <xs:element name="description">
        <xs:complexType>
            <xs:sequence maxOccurs="unbounded">
                <xs:element name="line">
                    <xs:complexType mixed="true">
                        <xs:sequence minOccurs="0"
                            maxOccurs="unbounded">
                            <xs:element name="important"
                              type="xs:string"/>
                        </xs:sequence>
                    </xs:complexType>
                </xs:element>
            </xs:sequence>
        </xs:complexType>
    </xs:element>

    <xs:element name="results">
        <xs:complexType>
            <xs:sequence maxOccurs="unbounded">
                <xs:element name="entry">
                    <xs:complexType>
                        <xs:sequence>
                            <xs:element name="test_name"
                              type="xs:string"/>
                            <xs:element name="passed"
                               type="xs:boolean"/>
                        </xs:sequence>
                    </xs:complexType>
                </xs:element>
            </xs:sequence>
        </xs:complexType>
    </xs:element>
</xs:schema>
```

CSS Stylesheet

A set of rules must be defined for describing how the XML document is to be rendered in **Author** mode. This is done using Cascading Style Sheets (CSS). CSS is a language used to describe how an HTML or XML document should be formatted by a browser. CSS is widely used in the majority of websites.

The elements from an XML document are displayed in the layout as a series of boxes. Some of the boxes contain text and may flow one after the other, from left to right. These are called inline boxes. There are also other types of boxes that flow one below the other (such as paragraphs). These are called block boxes.

For example, consider the way a traditional text editor arranges the text. A paragraph is a block, because it contains a vertical list of lines. The lines are also blocks. However, blocks that contain inline boxes arrange its children in a horizontal flow. That is why the paragraph lines are also blocks, while the traditional "bold" and "italic" sections are represented as inline boxes.

The CSS allows us to specify that some elements are displayed as tables. In CSS, a table is a complex structure and consists of rows and cells. The `table` element must have children that have a *table-row* style. Similarly, the `row` elements must contain elements with a *table-cell* style.

To make it easy to understand, the following section describes how each element from a schema is formatted using a CSS file. Note that this is just one of infinite possibilities for formatting the content.

report

The root of a report document. It should be rendered as a box that contains all other elements. To achieve this, the display type is set to **block**. Additionally, some margins are set for it. The CSS rule that matches this element is:

```
report{
    display:block;
    margin:1em;
}
```

title

The title of the report. Usually titles have a large font. The **block** display is used so that the subsequent elements will be placed below it, and its font is changed to double the size of the normal text.

```
title {
    display:block;
    font-size:2em;
}
```

description

Contains several lines of text describing the report. The lines of text are displayed one below the other, so the description has the **block** display. Also, the background color is changed to make it standout.

```
description {
    display:block;
    background-color:#EEEEFF;
    color:black;
}
```

line

A line of text in the description. A specific aspect is not defined and it just indicates that the display should be **block** style.

```
line {
    display:block;
}
```

important

Defines important text from the description. Since it can be mixed with text, its display property must be set to **inline**. Also, the text is emphasized with **bold**to make it easier to spot.

```
important {
    display:inline;
    font-weight:bold;
}
```

results

Displays the list of *test_names* and the results for each one. To make it easier to read, it is displayed as a **table**, with a green border and margins.

```
results{
    display:table;
    margin:2em;
    border:1px solid green;
}
```

entry

The results are displayed as a table so the entry is a row in the table. Thus, the display is **table-row**.

```
entry {
    display:table-row;
}
```

test_name, passed

The name of the individual test, and its result. They are cells in the results table with the display set to **table-cell**. Padding and a border are added to emphasize the table grid.

```

test_name, passed{
```

```
    display:table-cell;
    border:1px solid green;
    padding:20px;
}

passed{
    font-weight:bold;
}
```

The full content of the CSS file `test_report.css` is:

```
report {
    display:block;
    margin:1em;
}

description {
    display:block;
    background-color:#EEEEFF;
    color:black;
}

line {
    display:block;
}

important {
    display:inline;
    font-weight:bold;
}

title {
    display:block;
    font-size:2em;
}

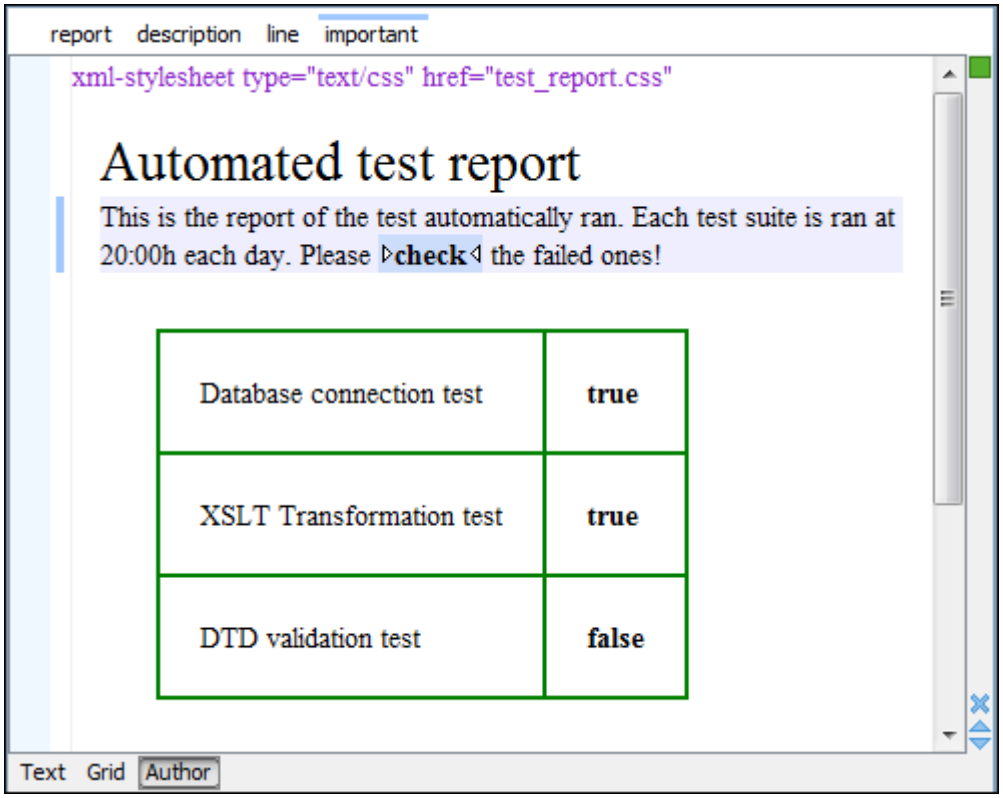
results{
    display:table;
    margin:2em;
    border:1px solid green;
}
```

```
entry {
    display:table-row;
}

test_name, passed{
    display:table-cell;
    border:1px solid green;
    padding:20px;
}

passed{
    font-weight:bold;
}
```

Figure 613. Report Rendered in Author Mode



Note:
You can edit attributes in-place in the **Author** mode using form-based controls *(on page 619)*.

XML Instance Template

Based on the XML Schema and CSS file Oxygen XML Editor can help the content author in loading, editing, and validating the test reports. An XML document template must be created as a kind of skeleton that the users can use as a starting point for creating new test reports. The template must be generic enough and reference the XML Schema file and the CSS stylesheet.

This is an example:

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet type="text/css" href="test_report.css"?>
<report xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="test_report.xsd">
  <title>Automated test report</title>
  <description>
    <line>This is the report of the test automatically ran.
      Each test suite is ran at 20:00h each day.
      Please <important>check</important> the failed ones!</line>
  </description>
  <results>
    <entry>
      <test_name>Database connection test</test_name>
      <passed>true</passed>
    </entry>
    <entry>
      <test_name>XSLT Transformation test</test_name>
      <passed>true</passed>
    </entry>
    <entry>
      <test_name>DTD validation test</test_name>
      <passed>false</passed>
    </entry>
  </results>
</report>
```

The processing instruction `xml-stylesheet` associates the CSS stylesheet to the XML file. The `href` pseudo attribute contains the URI reference to the stylesheet file. In the example, the CSS is in the same directory as the XML file.

The next step is to place the XSD file and the CSS file on a web server and modify the template to use the HTTP URLs, like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet type="text/css"
        href="http://www.mysite.com/reports/test_report.css"?>
<report xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:noNamespaceSchemaLocation=
        "http://www.mysite.com/reports/test_report.xsd">
    <title>Test report title</title>
    <description>
.......
```

If you want to share the files with other team members, you could create an archive containing the *test_report.xml*, *test_report.css*, and *test_report.xsd* and send it to the other users.

Creating and Configuring a Custom Framework

This basic tutorial is meant to provide an example of creating and configuring a custom document type (*framework (on page 3420)*). This basic tutorial offers examples for creating a custom schema, adjusting the authoring experience through custom CSS styling, and creating a custom action.

Step 1: Organize Framework Files

First, create a new folder for your customized *framework (on page 3420)*. This folder will be used to store all files related to the documentation *framework*. The folder structure will look something like this:

```
oxygen
  frameworks
     sdf
       schema
       css
```

The `frameworks` directory is the container where all the Oxygen XML Editor *framework* customizations are located. Each subdirectory contains files related to a specific type of XML documents (schemas, catalogs, stylesheets, CSS stylesheets, etc.) Distributing a *framework* means delivering a *framework* directory.

It is assumed that you have the right to create files and folders inside the Oxygen XML Editor installation directory. If you do not have this right, you will have to install another copy of the program in a folder you have access to, the home directory for instance, or your desktop.

To test your *framework* distribution, copy it in the `frameworks` directory of the newly installed application and start Oxygen XML Editor by running the provided start-up script files.

You should copy the created schema files `abs.xsd` and `sdf.xsd`, `sdf.xsd` being the main schema, to the `schema` directory and the CSS file `sdf.css` to the `css` directory.

Step 2: Extend an Existing Framework

The easiest way to create a custom *framework (on page 3420)* (document type) is by extending an existing built-in framework, such as DITA or DocBook, and then making modifications to it.

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association > Locations** *(on page 147)*. Add the path to your custom framework directory in the **Additional frameworks directories** list and click **OK** or **Apply** to save your changes.
2. Go to the **Document Type Association** preferences page *(on page 145)* and select an existing *framework* configuration (for example, **DocBook**) and use the **Extend** button to create an extension for it.

Step Result: This opens the **Document Type** Configuration dialog box *(on page 147)* where you can define the set of rules and settings for your custom framework.

3. Give the extension an appropriate name, select **External** for the **Storage** option, click the browsing button ( ) to specify the location of your custom framework directory.
4. Click **OK** to close the configuration dialog box and then **OK** or **Apply** to save your changes.

Results: You now have a fully functional *framework* that you can continue to customize.

Step 3: Create a Custom XML Schema

To illustrate an example of creating an XML Schema for a custom DocBook *framework (on page 3420)*, suppose the documents are either *articles* or *books*, and composed of *sections*. The *sections* may contain `<title>`, `<para>`, `<figure>`, `<table>`, and other `<section>` elements. To complete the picture, each section includes a `<def>` element from another namespace.

The first schema file:

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"
    targetNamespace="http://www.oxygenxml.com/sample/documentation"
    xmlns:doc="http://www.oxygenxml.com/sample/documentation"
    xmlns:abs="http://www.oxygenxml.com/sample/documentation/abstracts"
    elementFormDefault="qualified">

    <xs:import namespace=
    "http://www.oxygenxml.com/sample/documentation/abstracts"
     schemaLocation=
    "abs.xsd"/>
```

The namespace of the documents will be `http://www.oxygenxml.com/sample/documentation`. The namespace of the `<def>` element is `http://www.oxygenxml.com/sample/documentation/abstracts`.

Next, the structure of the sections is defined. They all start with a `<title>`, then have the optional `<def>` element then either a sequence of other sections, or a mixture of paragraphs, images, and tables.

```
<xs:element name="book" type="doc:sectionType"/>
<xs:element name="article" type="doc:sectionType"/>
<xs:element name="section" type="doc:sectionType"/>

<xs:complexType name="sectionType">
    <xs:sequence>
        <xs:element name="title" type="xs:string"/>
        <xs:element ref="abs:def" minOccurs="0"/>
```

```
        <xs:choice>
            <xs:sequence>
                <xs:element ref="doc:section" maxOccurs="unbounded"/>
            </xs:sequence>
            <xs:choice maxOccurs="unbounded">
                <xs:element ref="doc:para"/>
                <xs:element ref="doc:image"/>
                <xs:element ref="doc:table"/>
            </xs:choice>
        </xs:choice>
    </xs:sequence>
</xs:complexType>
```

The paragraph contains text and other custom styling markup, such as bold (`<b>`) and italic (`<i>`) elements.

```
<xs:element name="para" type="doc:paragraphType"/>

<xs:complexType name="paragraphType" mixed="true">
    <xs:choice minOccurs="0" maxOccurs="unbounded">
        <xs:element name="emphasis"/>
        <xs:element name="i"/>
    </xs:choice>
</xs:complexType>
```

The `<image>` element has an attribute with a reference to the file containing image data.

```
<xs:element name="image">
    <xs:complexType>
        <xs:attribute name="href" type="xs:anyURI" use="required"/>
    </xs:complexType>
</xs:element>
```

The `<table>` element contains a header row and then a sequence of rows (`<tr>` elements) each of them containing the cells. Each cell has the same content as the paragraphs.

```
 <xs:element name="table">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="header">
            <xs:complexType>
               <xs:sequence>
                   <xs:element name="td" maxOccurs="unbounded"
                        type="doc:paragraphType"/>
               </xs:sequence>
            </xs:complexType>
```

```
        </xs:element>
        <xs:element name="tr" maxOccurs="unbounded">
            <xs:complexType>
               <xs:sequence>
                   <xs:element name="td" type="doc:tdType"
                         maxOccurs="unbounded"/>
                </xs:sequence>
            </xs:complexType>
        </xs:element>
      </xs:sequence>
    </xs:complexType>
</xs:element>

<xs:complexType name="tdType">
    <xs:complexContent>
        <xs:extension base="doc:paragraphType">
            <xs:attribute name="row_span" type="xs:integer"/>
            <xs:attribute name="column_span" type="xs:integer"/>
        </xs:extension>
    </xs:complexContent>
</xs:complexType>
```

The `<def>` element is defined as a text only element in the imported schema `abs.xsd`:

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"
    targetNamespace=
     "http://www.oxygenxml.com/sample/documentation/abstracts">
    <xs:element name="def" type="xs:string"/>
</xs:schema>
```

Now the XML data structure will be styled.

Step 4: Associate the Schema to the Framework

In the bottom section of the **Document Type** configuration dialog box *(on page 147)*, there are a series of tabs. The **Schema** tab refers to the schema that is used for validation of the documents that match the defined association rules.

Important:
If the document references a schema directly (for example, using a `DOCTYPE` declaration, `xsi:schemaLocation` attribute, or a Relax NG `xml-model` processing instruction), the schema defined in this **Schema** tab is not used for validation or content completion.

Schema Type

Select from the combo box the value **XML Schema**.

Schema URI

Enter the value of the schema location (for example, `${framework}/schema/sdf.xsd`). Use the **${frameworks}** editor variable *(on page 340)* in the schema URI path instead of a full path to be valid for multiple Oxygen XML Editor installations.

Important:
The **${frameworks}** variable is expanded at the time of validation into the absolute location of the directory containing the *framework (on page 3420)*.

Step 5: Create a Custom CSS

If you read the Framework Customization Overview *(on page 2408)* then you already have some basic knowledge about creating simple styles. The example document contains elements from various namespaces, so you need to use CSS Level 3 extensions (supported by the **Author** mode layout engine) to associate specific properties with that element.

Defining the General Layout

Now the basic layout of the rendered documents is created.

Elements that are stacked one on top of the other are: `book`, `article`, `section`, `title`, `figure`, `table`, `image`. These elements are marked as having `block` style for display. Elements that are placed one after the other in a flowing sequence are: `b`, `i`. These will have `inline` display.

```
/* Vertical flow */
book,
section,
para,
title,
image,
ref {
    display:block;
}

/* Horizontal flow */
b,i {
    display:inline;
}
```

Important:
Having `block` display children in an `inline` display parent results in Oxygen XML Editor changing the style of the parent to `block` display.

Styling an Element

The title of any section must be bold and smaller than the title of the parent section. To create this effect, a sequence of CSS rules must be created. The `*` operator matches any element, it can be used to match titles having progressive depths in the document.

```
title{
    font-size: 2.4em;
    font-weight:bold;
}
* * title{
    font-size: 2.0em;
}
* * * title{
    font-size: 1.6em;
}
* * * * title{
    font-size: 1.2em;
}
```

It is useful to have before the title a constant text, indicating that it refers to a section. This text can include also the current section number. The `:before` and `:after` pseudo-elements will be used, plus the CSS counters.

First declare a counter named `sect` for each `book` or `article`. The counter is set to zero at the beginning of each such element:

```
book,
article{
    counter-reset:sect;
}
```

The `sect` counter is incremented with each `section`, that is a direct child of a `book` or an `article` element.

```
book > section,
article > section{
    counter-increment:sect;
}
```

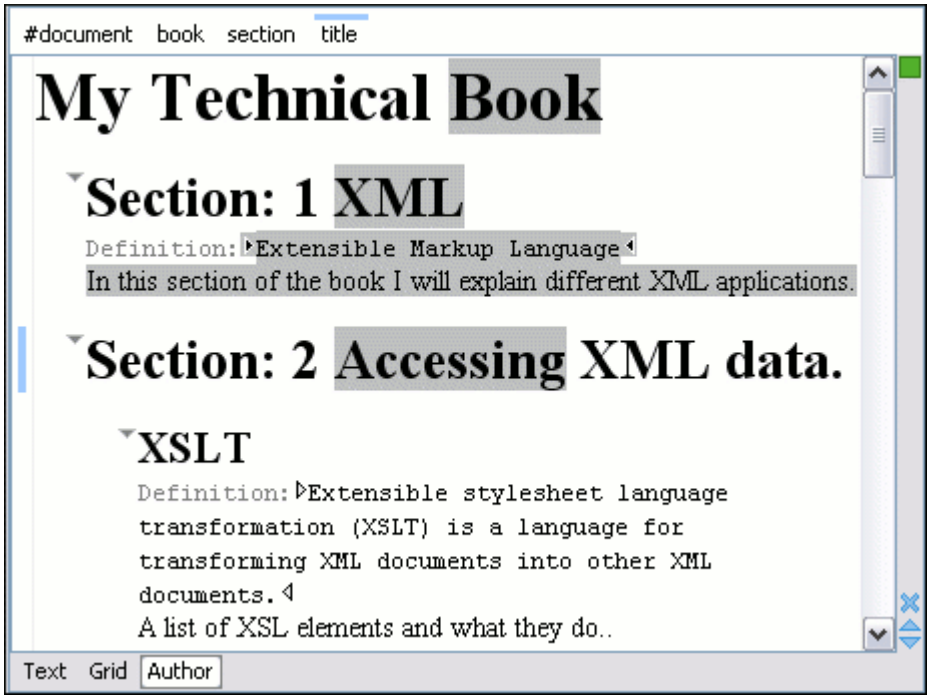
The "static" text that will prefix the section title is composed of the constant "Section ", followed by the decimal value of the `sect` counter and a dot.

```
book > section > title:before,
article > section > title:before{
    content: "Section " counter(sect) ". ";
}
```

To make the documents easy to read, you add a margin to the sections. In this way the higher nesting level, the larger the left side indent. The margin is expressed relatively to the parent bounds:

```
section{
    margin-left:1em;
    margin-top:1em;
}
```

Figure 614. A sample of nested sections and their titles.



In the above screenshot you can see a sample XML document rendered by the CSS stylesheet. The selection "avoids" the text that is generated by the CSS "content" property. This happens because the CSS generated text is not present in the XML document and is just a visual aid.

Styling Inline Elements

The "bold" style is obtained by using the `font-weight` CSS property with the value `bold`, while the "italic" style is specified by the `font-style` property:

```
b {
    font-weight:bold;
```

```
}

i {
    font-style:italic;
}
```

Styling Images

The CSS 2.1 does not specify how an element can be rendered as an image. To overpass this limitation, Oxygen XML Editor supports a CSS Level 3 extension allowing to load image data from a URL. The URL of the image must be specified by one of the element attributes and it is resolved through the catalogs specified in Oxygen XML Editor.

```
image{
    display:block;
    content: attr(href, url);
    margin-left:2em;
}
```

The `image` element has the required `@href` attribute of type `xs:anyURI`. The `@href` attribute contains an image location so the rendered content is obtained by using the function:

```
attr(href, url)
```

The first argument is the name of the attribute pointing to the image file. The second argument of the `attr` function specifies the type of the content. If the type has the `url` value, then Oxygen XML Editor identifies the content as being an image. If the type is missing, then the content will be the text representing the attribute value.

Oxygen XML Editor handles both absolute and relative specified URLs. If the image has an *absolute* URL location (for example: "http://www.oasis-open.org/images/standards/oasis_standard.jpg") then it is loaded directly from this location. If the image URL is *relative* specified to the XML document (for example: "images/my_screenshot.jpg") then the location is obtained by adding this value to the location of the edited XML document.

An image can also be referenced by the name of a DTD entity that specifies the location of the image file. For example, if the document declares an entity **graphic** that points to a JPEG image file:

```
<!ENTITY graphic SYSTEM "depo/keyboard_shortcut.jpg" NDATA JPEG>
```

and the image is referenced in the XML document by specifying the name of the entity as the value of an attribute:

```
<mediaobject>
    <imageobject>
        <imagedata entityref="graphic" scale="50"/>
```

```
    </imageobject>
</mediaobject>
```

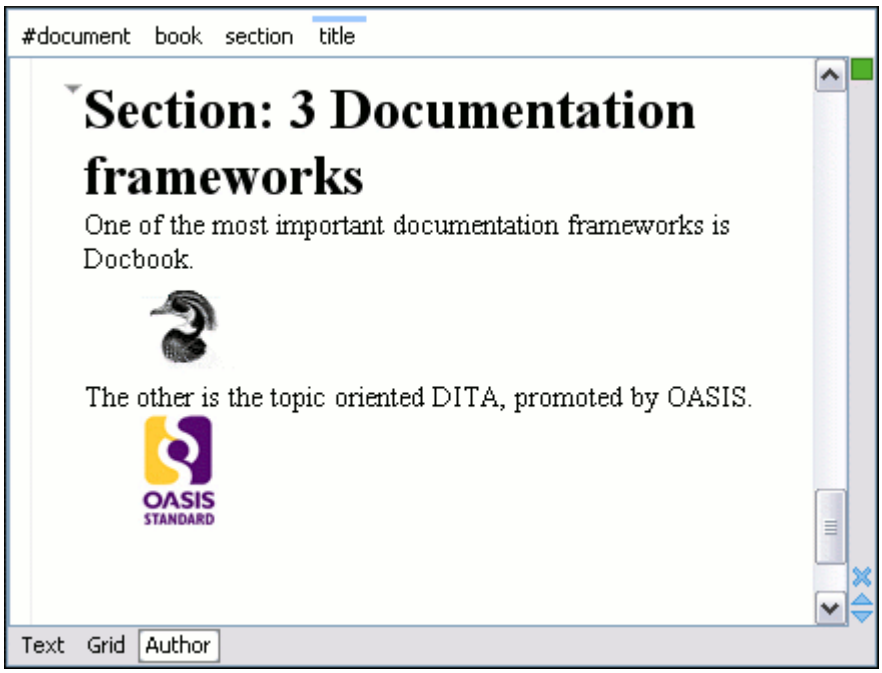
The CSS should use the functions `url`, `attr` and `unparsed-entity-uri` for displaying the image in the **Author** mode:

```
imagedata[entityref]{
    content: url(unparsed-entity-uri(attr(entityref)));
}
```

To take into account the value of the `@width` attribute of the `imagedata` and use it for resizing the image, the CSS can define the following rule:

```
imagedata[width]{
  width:attr(width, length);
}
```

Figure 615. Samples of images in Author



Step 6: Associate the Custom CSS to the Framework

Once you have customized your framework through CSS styling rules, you then need to associate the custom CSS file *(on page 153)*.

Step 7: Testing the Framework Customization

To test the new *framework (on page 3420)* customization, create an XML instance that conforms with the association rules that you specified in your *framework* customization. You will not specify an XML Schema location directly in the document, using an `xsi:schemaLocation` attribute. Instead, Oxygen XML Editor will detect its associated document type and use the specified schema.

```
<book xmlns="http://www.oxygenxml.com/sample/documentation"
      xmlns:abs="http://www.oxygenxml.com/sample/documentation/abstracts">

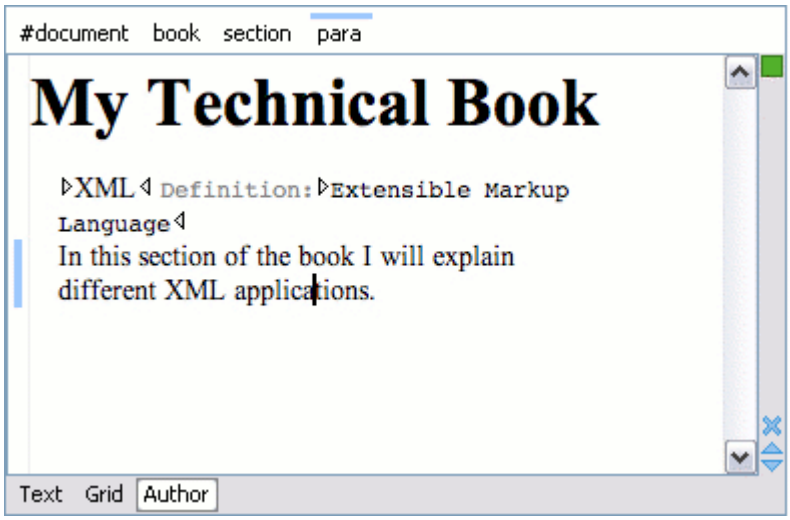
    <title>My Technical Book</title>
    <section>
        <title>XML</title>
        <abs:def>Extensible Markup Language</abs:def>
        <para>In this section of the book I will
           explain different XML applications.</para>
    </section>
</book>
```

When trying to validate the document there should be no errors. Now modify the `title` to `title2`. Validate again. This time there should be as error.

```
Invalid content was found starting with element
'title2'. One of '{"http://www.oxygenxml.com/sample/documentation":title}'
is expected.
```

Undo the tag name change, go to **Author** mode, and Oxygen XML Editor should load the CSS from the *document type association (on page 3419)* and create a layout similar to this:

Figure 616. Example: Testing a Framework Customization



CSS Support in Author Mode

The visual **Author** editing mode can be customized by creating CSS files to define styles for the XML elements and other components. The **Author** editing mode supports most CSS 2.1 selectors, numerous CSS 2.1 properties, and some CSS 3 selectors. Oxygen XML Editor also supports stylesheets coded with the LESS dynamic stylesheet language. Also, Oxygen XML Editor has added some custom functions and properties that extend the W3C CSS specification and are useful for a wide range of use-cases for developers who customize **Author** mode through custom *frameworks (on page 2248)*.

Resources

To see a visual demonstration of various advanced customization possibilities (including ideas for tailoring the editing experience using CSS), watch our Webinar: **Working with DITA in Oxygen - Customizing the Editing Experience**.

Associating a CSS with an XML Document

Associating a Stylesheet with an XML Document

The rendering of an XML document in the **Author** mode is driven by a CSS stylesheet that conforms to the version 2.1 of the CSS specification from the W3C consortium. Some CSS 3 features, such as namespaces and custom extensions, of the CSS specification are also supported. Oxygen XML Editor also supports stylesheets coded with the LESS dynamic stylesheet language.

There are several methods for associating a stylesheet (CSS or LESS) with an XML document:

- Insert the `xml-stylesheet` processing instruction with the `@type` attribute at the beginning of the XML document. The easiest way to do this is by using the  **Associate XSLT/CSS Stylesheet** action that is available on the toolbar or in the **Document > XML Document** menu.

  CSS example:

  ```
  <?xml-stylesheet type="text/css" href="test.css"?>
  ```

  LESS example:

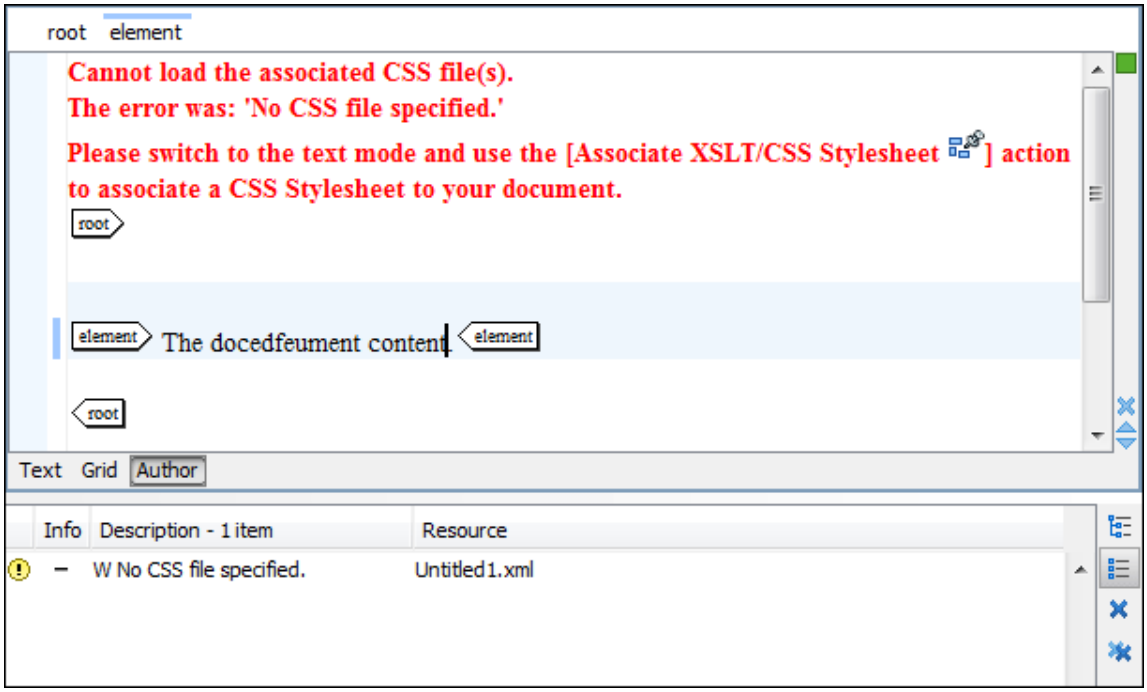
  ```
  <?xml-stylesheet type="text/css" href="test.less"?>
  ```

- Add a new CSS or LESS file to a *framework (on page 3420)* (document type). To do so, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association**. Edit the appropriate *framework*, open the **Author** tab, then the **CSS** subtab. Click the **New** button to add a new CSS or LESS file.

  Note:
  The built-in *frameworks* are read-only, so you need to **Extend** *(on page 146)* or **Duplicate** *(on page 146)* them to configure them as custom *frameworks*.

If a document has no CSS association or the referenced stylesheet files cannot be loaded, a default one is used. A warning message is also displayed at the beginning of the document, presenting the reason why the CSS cannot be loaded.

Figure 617. Document with no CSS association default rendering



For information about associating a CSS to a *framework* (document type), see Configuring and Managing Multiple CSS Styles for a Framework *(on page 2262)*.

Handling CSS Imports

When a CSS document contains imports to other CSS documents, the references are also passed through the *XML Catalog (on page 3425)* URI mappings to determine an indirect CSS referenced location.

Example: CSS Import

For example, if you can have a CSS import, such as:

```
@import "http://host/path/to/location/custom.css";
```

and then add your own *XML Catalog (on page 3425)* file that maps the location to a custom CSS in the **XML Catalog** preferences page *(on page 243)*:

```
<uri name="http://host/path/to/location/custom.css"
      uri="path/to/custom.css"/>
```

Adding a Custom Default CSS for Every XML Document

To add a custom CSS that is applied to every XML document, add a mapping in your *XML Catalog (on page 3425)* file that looks like this:

```
<uri name="http://www.oxygenxml.com/extensions/author/css/userCustom.css"
      uri="path/to/custom.css"/>
```

This extra mapped CSS location will be parsed every time the application processes the CSS stylesheets used to render the opened XML document in the visual **Author** editing mode. This allows your custom CSS to be used without the need to modify all other CSS stylesheets contributed in the document type configuration.

Editor Variables in CSS Imports

You can use various editor variables *(on page 332)* in CSS imports. When editing an XML document with an associated CSS in **Author** mode, the editor variables will be expanded and resolved.

Example: Editor Variable in a CSS Import

For example, the following editor variable:

```
@import "${framework(DITA)}/custom.css";
```

is resolved in the DITA *framework (on page 3420)* folder where the `custom.css` is placed. In the Document Type Association preferences page *(on page 145)*, you can see a list of document type. The name for your particular document type needs to be passed as a parameter to the `framework()` function.

Note:
If you use editor variables like `${cfdu}` (Current File Directory URL), it will be expanded to the URL of the current CSS document that contains the imports rather than the XML document that references the CSS.

Displaying Processing Instructions from Other XML Editors

By default, some external processing instructions are hidden (for example, certain processing instructions used to store metadata in other XML editors). If you want them to be displayed (for example, to edit them), they must be associated with the current document using a CSS *(on page 2425)* like this:

```
@namespace oxy "http://www.oxygenxml.com/extensions/author";
oxy|processing-instruction[Pub],
oxy|processing-instruction[PubTbl],
oxy|processing-instruction[xm-replace_text],
oxy|processing-instruction[xm-deletion_mark],
oxy|processing-instruction[xm-insertion_mark_start],
oxy|processing-instruction[xm-insertion_mark_end]
{
    display:block !important;
}
```

Specifying Media Types in the CSS

The CSS stylesheets can specify how a document is presented on different types of media (on the screen, paper, etc.) You can specify that some of the selectors from your CSS should be taken into account only in the

Oxygen XML Editor **Author** mode and ignored in other media types. This can be accomplished by using the `oxygen` media type.

Example: *oxygen* Media Type

```
b{
 font-weight:bold;
 display:inline;
}

@media oxygen{
 b{
  text-decoration:underline;
 }
}
```

This example results in the text being bold if the document is opened in a web browser that does not recognize `@media oxygen`, while the text is bold and underlined when opened in Oxygen XML Editor **Author** mode.

You can also use the `oxygen` media type to specify CSS selectors to be applied in certain operating systems or platforms by using the `os` and `platform` properties. For example, you can specify one set of style rules for displaying Oxygen XML Editor in Windows, and another set of style rules for macOS. The supported properties are as follows:

- **os** - The possible values are: `win`, `linux`, or `mac`.
- **platform** - The possible values are: `standalone`, `eclipse`, or `webapp`.

Example: *os* and *platform* Properties

```
@media oxygen AND (os:"win") AND (platform:"standalone") {
    p{
        content:"PPP";
    }
}
```

Related information

@media Rule *(on page 2429)*

CSS At-Rules

Oxygen XML Editor supports some of the standard at-rules specified by CSS Level 2.1 and 3. The `@media` rule also include support for some style rules that are specific to Oxygen XML Editor.

@font-face At-Rule

Oxygen XML Editor allows you to use custom fonts in the **Author** mode by specifying them in the CSS using the `@font-face` media type. Only the `src` and `font-family` CSS properties can be used for this media type.

Example: *@font-face* Rule

```
@font-face{
    font-family:"Baroque Script";
    /*The location of the loaded TTF font must be relative to the CSS*/
    src:url("BaroqueScript.ttf");
}
```

@media Rule

The *@media* rule allows you to set different style rules for multiple types of media in the same stylesheet. For example, you can set the font size to be different on the screen than on paper. Oxygen XML Editor supports several media types, allowing you to set the style rules for presenting a document on various media (on screen, paper, etc.)

Supported Media Types

- **screen** - The styles marked with this media type are used only for rendering a document on screen.
- **print** - The styles marked with this media type are used only for printing a document.
- **all** - The styles marked with this media type are used for rendering a document in all supported types of media.
- **oxygen** - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor **Author** mode. For more information, see Specifying Media Types in the CSS *(on page 2427)*.
- **oxygen-dark-theme** - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor **Author** mode when a dark theme is used (for example, *Graphite*).
- **oxygen-high-contrast-black** - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor **Author** mode on a Windows High Contrast Theme with a black background.
- **oxygen-high-contrast-white** - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor **Author** mode on a Windows High Contrast Theme with a white background.

Example: *@media* Rule

```
@media oxygen{
 b{
  text-decoration:underline;
 }
}
@media oxygen-high-contrast-white{
```

```
 b{
  font-weight:bold;
 }
}
```

Supported Properties

Oxygen XML Editor also supports a few properties to set specific style rules that depend upon the size of the visible area in **Author** mode. These supported properties are as follows:

- **min-width** - The styles selected in this property are applied if the visible area in **Author** mode is equal to or greater than the specified value.
- **max-width** - The styles selected in this property are applied if the visible area in **Author** mode is less than or equal to the specified value.

Example: *min-width* and *max-width* Properties

```
@media (min-width:500px){
 p{
    content:'XXX';
 }
}
@media (max-width:700px){
 p:after{
    content:'yyy';
 }
}
```

Standard W3C CSS Supported Features

Oxygen XML Editor supports most of the CSS Level 3 selectors and most of the CSS Level 2.1 properties

Supported CSS Selectors

Tip:
CSS rules that match attributes are always more specific than element selectors. For more information, see https://drafts.csswg.org/selectors-3/#specificity.

The following table lists the CSS selectors that are supported in Oxygen XML Editor:

Expression	Name	CSS Level	Description / Example
`*`	Universal selector	CSS Level 2	Matches any element
`E`	Type selector	CSS Level 2	Matches any `E` element (i. e. an element with the local name `E`)
`E F`	Descendant selector	CSS Level 2	Matches any `F` element that is a descendant of an `E` element.
`E > F`	Child selectors	CSS Level 2	Matches any `F` element that is a child of an element `E`.
`E:lang(c)`	Language pseudo-class	CSS Level 2	Matches element of type `E` if it is in (human) language `c` (the document language specifies how language is determined).
`E + F`	Adjacent selector	CSS Level 2	Matches any `F` element immediately preceded by a sibling element `E`.
`E ~ F`	General sibling selector	CSS Level 3	Matches any `F` element preceded by a sibling element `E`.
`E[foo]`	Attribute selector	CSS Level 2	Matches any `E` element with the `"foo"` attribute set (whatever the value).
`E[foo="warning"]`	Attribute selector with value	CSS Level 2	Matches any `E` element whose `"foo"` attribute value is exactly equal to `"warning"`.
`E[foo~="warning"]`	Attribute selector containing value	CSS Level 2	Matches any `E` element whose `"foo"` attribute value is a list of space-separated values, one of which is exactly equal to `"warning"`.
`E[lang|="en"]`	Attribute selector containing hyphen separated values	CSS Level 2	Matches any `E` element whose `"lang"` attribute has a hyphen-separated list of values beginning (from the left) with `"en"`.
`E:before and E:after`	Pseudo-elements	CSS Level 2	The `':before'` and `':after'` pseudo-elements can be used to insert generated content before or after an element's content.
`E:first-child`	The first-child pseudo-class	CSS Level 2	Matches element `E` when `E` is the first child of its parent.

Expression	Name	CSS Level	Description / Example
`E:not(s)`	Negation pseudo-class	CSS Level 2	An E element that does not match simple selector s.
`E:has`	Relational pseudo-class	CSS Level 4	The `:has()` relational pseudo-class is a functional pseudo-class that takes a relative selector as an argument. For more information, see :has Relational Pseudo-Class *(on page 2436)*.
`E:hover`	The hover pseudo-class	CSS Level 2	The `:hover` pseudo-class applies while the user designates an element with a pointing device, but does not necessarily activate it. When moving the pointing device over an element, all the parent elements up to the root are taken into account.
`E:focus`	The focus pseudo-class	CSS Level 2	The `:focus` pseudo-class applies while an element has the focus (accepts keyboard input).
`E:focus-within`	The generalized input focus pseudo-class	CSS Level 4	The `:focus-within` pseudo-class applies to elements that will have the `:focus` pseudo-class applied. Additionally, the ancestors of an element that matches `:focus-within` also match.
`E:marker`	The marker pseudo-class	CSS Level 4	The `::marker` pseudo-element represents the automatically generated marker box of a list item.
`E#myid`	The ID selector	CSS Level 2	Matches any E element with ID equal to "myid". **Important:** Limitation: In Oxygen XML Editor the match is performed only taking into ac-

Expression	Name	CSS Level	Description / Example
			count the attributes with the exact name: *"id"*.
`E[att^="val"]`	Substring matching attribute selector	CSS Level 3	An E element whose `att` attribute value begins exactly with the string `val`.
`E[att$="val"]`	Substring matching attribute selector	CSS Level 3	An E element whose `att` attribute value ends exactly with the string `val`.
`E[att*="val"]`	Substring matching attribute selector	CSS Level 3	An E element whose `att` attribute value contains the substring `val`.
`E:root`	Root pseudo-class	CSS Level 3	Matches the root element of the document. In HTML, the root element is always the HTML element.
`E:empty`	Empty pseudo-class	CSS Level 3	An E element that has no text or child elements.
`E:nth-child(n)`	The nth-child pseudo-class	CSS Level 3	An E element, the nth child of its parent.
`E:nth-last-child(n)`	The nth-last-child pseudo-class	CSS Level 3	An E element, the nth child of its parent, counting from the last one.
`E:nth-of-type(n)`	The nth-of-type pseudo-class	CSS Level 3	An E element, the nth sibling of its type.
`E:nth-last-of-type(n)`	The nth-last-of-type pseudo-class	CSS Level 3	An E element, the nth sibling of its type, counting from the last one.
`E:last-child`	The last-child pseudo-class	CSS Level 3	An E element, last child of its parent.
`E:first-of-type`	The first-of-type pseudo-class	CSS Level 3	An E element, first sibling of its type.
`E:last-of-type`	The last-of-type pseudo-class	CSS Level 3	An E element, last sibling of its type.
`E:only-child`	The only-child pseudo-class	CSS Level 3	An E element, only child of its parent.
`E:only-of-type`	The only-of-type pseudo-class	CSS Level 3	An E element, only sibling of its type.

Expression	Name	CSS Level	Description / Example
`ns|E`	Element namespace selector	CSS Level 3	An element that has the local name E and the namespace given by the prefix `ns`. The namespace prefix can be bound to a URI by the at-rule: `@namespace ns "http://some_namespace_uri";` See Namespace Selector *(on page 2434)*.
`E!>F`	The subject selector	CSS Level 4 (experimental)	An element that has the local name E and has a child F. See Subject Selector *(on page 2435)*.

Namespace Selector

In the CSS 2.1 standard, the element selectors ignore the namespaces of the elements they are matching. Only the local name of the elements are considered in the selector matching process.

Oxygen XML Editor uses a different approach that is similar to the CSS Level 3 specification. If the element name from the CSS selector is not preceded by a namespace prefix it is considered to match an element with the same local name as the selector value and ANY namespace. Otherwise, the element must match both the local name and the namespace.

In CSS up to version 2.1, the name tokens from selectors match all elements from ANY namespace that have the same local name. Example:

```
<x:b xmlns:x="ns_x"/>
<y:b xmlns:y="ns_y"/>
```

Are both matched by the rule:

```
b {font-weight:bold}
```

Starting with CSS Level 3, you can create selectors that are namespace aware.

Example: Defining prefixed and default namespaces

Given the namespace declarations:

```
@namespace sync "http://sync.example.org";
@namespace "http://example.com/foo";
```

Then:

sync|A

Represents the name A in the `http://sync.example.org` namespace.

***|B**

Represents the name B in ANY namespace, including NO NAMESPACE.

C

Represents the name C in ANY namespace, including NO NAMESPACE.

Example: Defining prefixed namespaces combined with pseudo-elements

To match the `<def>` element its namespace declares, bind it to the *abs* prefix and then write a CSS rule:

```
@namespace abs "http://www.oxygenxml.com/sample/documentation/abstracts";
```

Then:

abs|def

Represents the name "def" in the `http://www.oxygenxml.com/sample/documentation/abstracts` namespace.

abs|def:before

Represents the :before pseudo-element of the "def" element from the `http://www.oxygenxml.com/sample/documentation/abstracts` namespace.

Subject Selector

Oxygen XML Editor supports the subject selector described in CSS Level 4 (currently a working draft at W3C http://www.w3.org/TR/selectors4/). This selector matches a structure of the document, but unlike a compound selector, the styling properties are applied to the subject element (the one marked with "!") instead of the last element from the path.

The subject of the selector can be explicitly identified by appending an exclamation mark (!) to one of the compound selectors in a selector. Although the element structure that the selector represents is the same with or without the exclamation mark, indicating the subject in this way can change which compound selector represents the subject in that structure.

Example:

```
table! > caption {
  border: 1px solid red;
}
```

A border will be drawn to the table elements that contain a caption, as direct child.

This is different from:

```
table > caption {
  border: 1px solid red;
}
```

This draws a border around the caption.

Taking Processing Instructions into Account in CSS Subject Selectors

You can test for the existence of specific processing instructions (`PI`) in the child hierarchy of a subject selector.

For example:

```
@namespace oxy "http://www.oxygenxml.com/extensions/author";

chapter! > oxy|processing-instruction[important][level="high"]{
  color:red;
}
```

This would change the color of a DocBook chapter to red if it contains the `important` processing instruction:

```
<chapter>
   <title>A title</title>
   <?important level='high'?>
</chapter>
```

Descendant Selectors Limitation

Important:
The current implementation has a known limitation. The general descendant selectors are taken into account as direct child selectors. For example, the following two CSS selectors are considered equivalent:

```
a:has(b c)
```

and:

```
a:has(b>c)
```

Related information
:has Relational Pseudo-Class *(on page 2436)*

:has Relational Pseudo-Class

Oxygen XML Editor supports the CSS Level 4 subject selector (currently a working draft at W3C http://www.w3.org/TR/selectors4/), as described in Subject Selector *(on page 2435)*. Oxygen XML Editor also

supports the `:has` relational pseudo-class that has similar functionality and it can match an element by taking its child elements into account. For more information, see https://drafts.csswg.org/selectors-4/#relational.

You can create conditions that take into account the structure of the matching element.

Example: *has* Pseudo Class

```
table:has( tbody > thead){
 border: 1px solid red;
}
```

This example will result in a border being drawn for the table elements that contain at least a `<thead>` element in the `<tbody>` element.

Taking Processing Instructions into Account in CSS Subject Selectors

You can test for the existence of specific processing instructions (`PI`) in the child hierarchy of a subject selector.

For example:

```
@namespace oxy "http://www.oxygenxml.com/extensions/author";

chapter! > oxy|processing-instruction[important][level="high"]{
  color:red;
}
```

This would change the color of a DocBook chapter to red if it contains the `important` processing instruction:

```
<chapter>
   <title>A title</title>
   <?important level='high'?>
</chapter>
```

Descendant Selectors Limitation

Important:
The current implementation has a known limitation. The general descendant selectors are taken into account as direct child selectors. For example, the following two CSS selectors are considered equivalent:

```
a:has(b c)
```

and:

```
a:has(b>c)
```

Supported CSS Properties

Oxygen XML Editor validates all CSS 2.1 properties, but does not render *aural* and *paged* categories properties in **Author** mode, as well as some of the values of the *visual* category that are listed below under the **Ignored Values** column. For the Oxygen XML Editor-specific (extension) CSS properties, see CSS Extensions *(on page 2451)*.

Name	Rendered Values	Ignored Values
background	background-color | background-image | background-position | background-repeat | inherit | initial | unset	
background-attachment	NONE	
background-color	<color> | inherit | initial | unset	transparent
background-image	<uri> | none | inherit | initial | unset	
background-position	top | right | bottom | left | center | initial | unset	<percentage> | <length> *(on page 2443)*
background-repeat	repeat | repeat-x | repeat-y | no-repeat | inherit | initial | unset	
border	[<border-width> || <border-style> || <border-color>] | inherit | initial | unset Not yet supported on table row or table row groups.	
border-collapse	NONE	
border-color	<color> | inherit | initial | unset	transparent
border-radius	<length> *(on page 2443)* | <percentage> Works only for border-type 'solid', 'dashed', 'dotted', 'wave'. Does not work when background-image is specified. Percent values are not fully supported.	
border-spacing	NONE	
border-style	<border-style> | inherit | initial | unset	

Name	Rendered Values	Ignored Values
border-top / border-right / border-bottom / border-left	[<border-width> || <border-style> || <border-color>] | inherit | initial | unset	
border-top-color / border-right-color / border-bottom-color / border-left-color	<color> | inherit | initial | unset	transparent

CSS Extensions *(on page 2451)*

Transparent Colors

CSS3 supports RGBA colors. The RGBA declaration allows you to set opacity (via the Alpha channel) as part of the color value. A value of `0` corresponds to a completely transparent color, while a value of `1` corresponds to a completely opaque color. To specify a value, you can use either a *real* number between `0` and `1`, or a percent.

Example: RGBA Color

```
personnel:before {
    display:block;
    padding: 1em;
    font-size: 1.8em;
```

```
    content: "Employees";
    font-weight: bold;
    color:#EEEEEE;
    background-color: rgba(50, 50, 50, 0.6);
}
```

attr() Function: Properties Values Collected from the Edited Document

In CSS Level 2.1 you may collect attribute values and use them as content *only* for the pseudo-elements. For instance, the `:before` pseudo-element can be used to insert some content before an element. This is valid in CSS 2.1:

```
title:before{
  content: "[Audience Level: " attr(audience) "]";
}
```

If the `<title>` element from the XML document is:

```
<title audience="Expert">Changing the Timing Belt</title>
```

Then the title will be displayed as:

```
[Audience Level: Expert] Changing the Timimg Belt
```

In Oxygen XML Editor, the use of `attr()` function is available not only for the `content` property, but also for any other property. This is similar to the CSS Level 3 working draft: http://www.w3.org/TR/2006/WD-css3-values-20060919/#functional. The arguments of the function are:

```
attr ( attribute_name , attribute_type , default_value )
```

attribute_name

The attribute name. This argument is required.

attribute_type

The attribute type. This argument is optional. If it is missing, argument's type is considered `string`. This argument indicates what is the meaning of the attribute value and helps to perform conversions of this value. Oxygen XML Editor accepts one of the following types:

color

The value represents a color. The attribute may specify a color in various formats. Oxygen XML Editor supports colors specified either by name (`red`, `blue`, `green`, etc.) or as an RGB hexadecimal value `#FFEEFF`.

url

The value is a URL pointing to a media object. Oxygen XML Editor supports only images. The attribute value can be a complete URL, or a relative one to the XML document. Note that this URL is also resolved through the catalog resolver.

integer

The value must be interpreted as an integer.

number

The value must be interpreted as a float number.

length

The value must be interpreted as an integer.

percentage

The value must be interpreted relative to another value (length, size) expressed in percents.

em

The value must be interpreted as a size. 1 em is equal to the *font-size* of the relevant font.

ex

The value must be interpreted as a size. 1 ex is equal to the *height* of the **x** character of the relevant font.

px

The value must be interpreted as a size expressed in pixels relative to the viewing device.

mm

The value must be interpreted as a size expressed in millimeters.

cm

The value must be interpreted as a size expressed in centimeters.

in

The value must be interpreted as a size expressed in inches. 1 inch is equal to 2.54 centimeters.

pt

The value must be interpreted as a size expressed in points. The points used by CSS2 are equal to 1/72th of an inch.

pc

The value must be interpreted as a size expressed in picas. 1 pica is equal to 12 points.

default_value

This argument specifies a value that is used by default if the attribute value is missing. This argument is optional.

Example: *attr* Function

Consider the following XML instance:

```
<sample>
   <para bg_color="#AAAAFF">Blue paragraph.</para>
   <para bg_color="red">Red paragraph.</para>
   <para bg_color="red" font_size="2">Red paragraph with large font.</para>
   <para bg_color="#00AA00" font_size="0.8" space="4">
        Green paragraph with small font and margin.</para>
</sample>
```

The `<para>` elements have `@bg_color` attributes with RGB color values (such as `#AAAAFF`). You can use the `attr()` function to change the elements appearance in the editor based on the value of this attribute:

```
background-color:attr(bg_color, color);
```

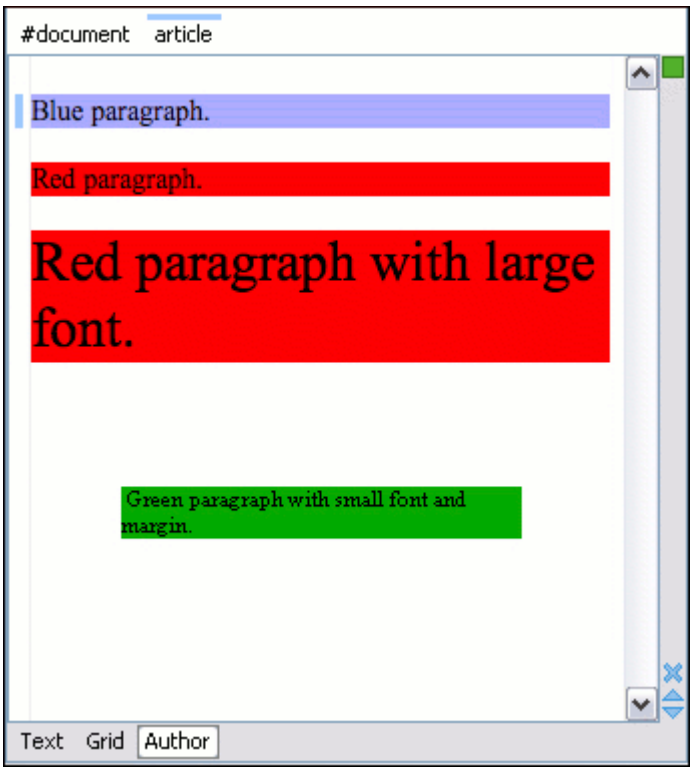
The `font_size` represents the font size in *em* units. You can use this value to change the style of the element:

```
font-size:attr(font_size, em);
```

The complete CSS rule is:

```
para{
 display:block;
 background-color:attr(bg_color, color);
 font-size:attr(font_size, em);
 margin:attr(space, em);
}
```

The document is rendered as:



CSS Level 3 target-counter() and target-counters() Functions

The CSS Level 3 functions *target-counter* and *target-counters* can be used as values for the `content` property to retrieve counter values and display information obtained from a target at the end of a link.

The *target-counter* Function

This function retrieves the value of the innermost counter with a given name.

```
target-counter ( <fragment> , <counter-name> [ , <counter-style> ] ? )
```

fragment

The URI fragment pointing to the ID of the target element.

counter-name

The name of the counter. This argument is required.

counter-style

This optional argument can be used to format the result.

Example:

HTML:

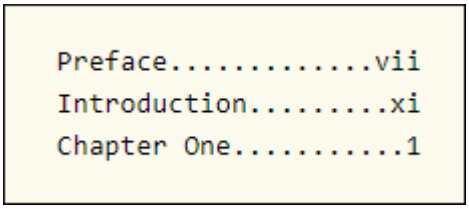
```
<nav>
  <ol>
    <li class="frontmatter"><a href="#pref_01">Preface</a></li>
```

```
    <li class="frontmatter"><a href="#intr_01">Introduction</a></li>
    <li class="bodymatter"><a href="#chap_01">Chapter One</a></li>
  </ol>
</nav>
```

CSS:

```
.frontmatter a::after { content: leader('.') target-counter(attr(href), page, lower-roman) }
.bodymatter a::after { content: leader('.') target-counter(attr(href), page, decimal) }
```

Result:



The *target-counters* Function

This function fetches the value of all counters of a given name from the end of a link and formats them by inserting a given string between the value of each nested counter.

```
target-counter ( <fragment> , <counter-name> , <delimiter> [ , <counter-style> ] ? )
```

fragment

The URI fragment pointing to the ID of the target element.

counter-name

The name of the counter. This argument is required.

delimiter

The string to be inserted between the value of each nested counter. This argument is required.

counter-style

This optional argument can be used to format the result.

https://www.w3.org/TR/css-gcpm-3/#target-counter

https://www.w3.org/TR/css-gcpm-3/#target-counters

calc() Function

The `calc()` function allows mathematical expressions with addition (+), subtraction (-), multiplication (*), division (/) to be used as component values. Percentages are solved relative to the dimensions of the containing parent block. It can be used when length values are accepted:

```
elem {
 width: calc(100% - 1em);
}
```

For more information, see: https://drafts.csswg.org/css-values-3/#calc-notation

Custom CSS Properties (CSS Variables)

Custom properties (also referred to as *CSS variables*) are properties defined by CSS authors that contain specific values to be reused throughout a document.

Complex websites have many CSS rules, often with a lot of repeated values. For example, the same color might be used in dozens of different places, requiring a global search-and-replace operation if that color needs to be changed. Custom properties allow a value to be stored in one place, then referenced in multiple other places. An additional benefit is semantic identifiers. For example, `--main-text-color` is easier to understand than `#00ff00`, especially if this same color is also used in other contexts.

Custom properties follow the same rules as other CSS properties, so you are able to define and use them at multiple levels, following standard CSS cascading and specificity rules.

Usage

A custom property name begins with a double hyphen (`--`) and its value that can be any valid CSS value. You use the custom property value by specifying your custom property name inside the *var()* function, in place of a regular property value:

Defining a Custom Property

```
element {
  --main-bg-color: brown;
  background-color: var(--main-bg-color);
}
```

Note:
Custom property names are case sensitive: *--my-color* will be treated as a separate custom property from *--My-color*.

Inheritance of Custom Properties

If you define a custom property on an element, you will be able to access it on all of its descendents.

Inheritance

```
<one>
  <two>
    <three/>
    <four/>
  </two>
</one>
```

```
one {
  --color:green;
}

three {
  --color:red;
}

* {
  color: var(--color);
}
```

Result:

- `<one>` has the color green.
- `<two>` has the color green.
- `<three>` has the color red.
- `<four>` has the color green.

Custom Properties Fallback Values

The *var()* function has two arguments. The first argument is the name of the custom property to be substituted. The second argument (optional) is a fallback value, which is used as the substitution value when the referenced custom property is invalid or undefined.

Specifying a Fallback Value

```
one {
  color: var(--color, blue);
}

one {
  color: var(--color, var(--fallback-color, red));
}
```

Dependencies

A custom property can reference the value of another custom property through the *var()* function.

A Custom Property Safely Using a Variable

```
:root {
  --border-color: red;
  --main-border: 1px solid var(--border-color, green);
}

p {
  border: var(--main-border);
}
```

Combining Custom Variables with `calc()`

```
:root {
  --foo: 10px;
  --bar: calc(var(--foo) + 10px);
}

p {
  font-size: var(--bar);
}
```

CAUTION:
This can create cyclic dependencies where two or more custom properties each attempt to reference each other.

An Invalid Situation of Variables Depending on Each Other

```
:root {
  --color:    var(--bg-color);
  --bg-color: var(--color);
}
```

CSS Extensions

CSS stylesheets provide support for displaying documents. When editing non-standard documents, Oxygen XML Editor CSS extensions are useful.

Examples of how they can be used:

- Property for marking *foldable elements (on page 3420)* in large files.
- Enforcing a display mode for the XML tags, regardless of the current mode selected by the user.

- Constructing a URL from a relative path location.
- String processing functions.

Built-in CSS Selectors

When Oxygen XML Editor renders content in the **Author** mode, it adds built-in CSS selectors (in addition to the CSS stylesheets linked in the XML or specified in the document type associated to the XML document). These built-in CSS selectors are processed before all other CSS content, but they can be overwritten if the CSS developer wants to modify a default behavior.

List of CSS Selector Contributed by Oxygen XML Editor

```
@namespace oxy "http://www.oxygenxml.com/extensions/author";
@namespace xi "http://www.w3.org/2001/XInclude";
@namespace xlink "http://www.w3.org/1999/xlink";
@namespace svg "http://www.w3.org/2000/svg";
@namespace mml "http://www.w3.org/1998/Math/MathML";

    xi|include:after{
        color:#808080 !important;
    }
}

/*
 * EXM-40349
 *
 * In DIFF these place holder PIs are not handled so we treat them as normal PIs with a bit of
 styling.
 *
 */
oxy|processing-instruction[oxy-placeholder] {
    visibility:-oxy-collapse-text;
    -oxy-display-tags:none;
}

oxy|processing-instruction[oxy-placeholder]:before {
    background-color: rgba(192, 192, 192, 0.2) !important;
    color: rgba(0, 0, 0, 0.6) !important;
    font-weight:bold;
    /* When there isn't an associated CSS the NO_CSS rules hide the PIs. @see
 AuthorViewport.CSS_ERROR_END */
    display:-oxy-morph;
    content: attr(content) !important;
}

@media oxygen-high-contrast-black, oxygen-dark-theme{
   oxy|processing-instruction[oxy-placeholder]:before {
    background-color: rgba(0, 0, 0, 0.15) !important;
    color: rgb(156, 156, 156) !important;
    }
    /* ====================================
    *
    * built-in oXygen elements
    *
    */
    oxy|comment {
        color: #a2a2a2 !important;
        background-color: transparent !important;
    }
```

```
    oxy|reference,
    oxy|entity {
        background-color: rgb(100, 100, 100) !important;
    }
}
```

Example:

To show all entities in the **Author** mode as transparent, without a gray background, first define in your CSS after all imports the namespace:

```
@namespace oxy "http://www.oxygenxml.com/extensions/author";
```

and then add the following selector:

```
oxy|entity {
    background-color: inherit !important;
}
```

Additional CSS Selectors

Oxygen XML Editor provides support for selecting additional types of nodes. These custom selectors apply to: *document*, *doctype*, *processing-instruction*, *comment*, *CDATA sections*, *entities*, and *reference sections*. *Processing-instructions* are not displayed by default. To display them, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Editor > Author**, and select **Show processing instructions**.

Note:
The custom selectors are presented in the default CSS for **Author** mode and all of their properties are marked with the *!important* flag. For this reason, you have to set the *!important* flag on each property of the custom selectors from your CSS to be applicable.

For the custom selectors to work in your CSS stylesheets, declare the **Author** mode extensions namespace at the beginning of the stylesheet documents:

```
@namespace oxy url('http://www.oxygenxml.com/extensions/author');
```

- **oxy|document** - The `oxy|document` selector matches the entire document:

  ```
  oxy|document {
      display:block !important;
  }
  ```

- **oxy|doctype** - The following example changes the rendering of `doctype` sections:

  ```
  oxy|doctype {
      display:block !important;
      color:blue !important;
  ```

```
    background-color:transparent !important;
}
```

- **oxy|processing-instruction** - To match the processing instructions, you can use the `oxy|processing-instruction` selector:

```
oxy|processing-instruction {
    display:block !important;
    color:purple !important;
    background-color:transparent !important;
}
```

A processing instruction usually has a target and one or more pseudo attributes:

```
<?target_name data="b"?>
```

You can match a processing instruction with a particular target from the CSS using the following construct:

```
oxy|processing-instruction[target_name]
```

You can also match the processing instructions having a certain target and pseudo attribute value, such as:

```
oxy|processing-instruction[target_name][data="b"]
```

- **oxy|comment** - The XML comments displayed in **Author** mode can be changed using the `oxy|comment` selector:

```
oxy|comment {
    display:block !important;
    color:green !important;
    background-color:transparent !important;
}
```

- **oxy|cdata** - The `oxy|cdata` selector matches `CDATA` sections:

```
oxy|cdata{
    display:block !important;
    color:gray !important;
    background-color:transparent !important;
}
```

- **oxy|entity** - The `oxy|entity` selector matches the entity content:

```
oxy|entity {
    display:morph !important;
    editable:false !important;
    color:orange !important;
```

```
    background-color:transparent !important;
}
```

To match particular entities, use the `oxy|entity` selector in expressions such as:

```
oxy|entity[name='amp'],
oxy|entity[name='lt'],
oxy|entity[name='gt'],
oxy|entity[name='quot'],
oxy|entity[name='apos'],
oxy|entity[name^='#']{
    -oxy-display-tags: none;
}
```

- **oxy|reference** - The *references to entities*, *XInclude*, and DITA `@conref` and `@conkeyref` attributes are expanded by default in **Author** mode and the referenced content is displayed. The referenced resources are displayed inside the element or entity that references them.

  You can use the `reference` property to customize the way these references are rendered in **Author** mode:

  ```
  oxy|reference {
    border:1px solid gray !important;
  }
  ```

  In the **Author** mode, content is highlighted when text contains comments *(on page 652)* and changes (if *Track Changes (on page 652)* was active when the content was modified).

  If this content is referenced, the **Author** mode does not display the highlighted areas in the new context. If you want to mark the existence of the comments and changes, you can use the `oxy|reference[comments]`, `oxy|reference[changeTracking]`, and `oxy|reference[changeTracking][comments]` selectors.

  

  Note:
  Two artificial attributes (`comments` and `changeTracking`) are set on the reference node, containing information about the number of comments and tracked changes in the content.

  - The following example represents the customization of the reference fragments that contain comments:

    ```
    oxy|reference[comments]:before {
      content: "Comments: " attr(comments) !important;
    }
    ```

  - To match reference fragments based on the fact that they contain tracked changes inside, use the `oxy|reference[changeTracking]` selector:

```
oxy|reference[changeTracking]:before {
  content: "Change tracking: " attr(changeTracking) !important;
}
```

- Here is an example of how you can set a custom color for the reference containing both tracked changes and comments:

```
oxy|reference[changeTracking][comments]:before {
  content: "Change tracking: " attr(changeTracking)
           " and comments: " attr(comments) !important;
}
```

Figure 618. Example: A Document Rendered Using these Rules

Additional CSS Properties

Oxygen XML Editor provides various additional CSS properties to extend the standard CSS properties.

Append Content Properties: -oxy-append-content / -oxy-prepend-content

Used to append specified content.

`-oxy-append-content` Property

This property appends the specified content to the content generated by other matching CSS rules of lesser specificity. Unlike the `content` property, where only the value from the rule with the greatest specificity is taken into account, the `-oxy-append-content` property adds content to that generated by the lesser specificity rules into a new compound content.

Example:

```
element:before{
    content: "Hello";
}
element:before{
    -oxy-append-content: " World!";
}
```

The content shown before the `element` will be `Hello World!`.

`-oxy-prepend-content` Property

Prepends the specified content to the content generated by other matching CSS rules of lesser specificity. Unlike the `content` property, where only the value from the rule with the greatest specificity is taken into account, the `-oxy-prepend-content` prepends content to that generated by the lesser specificity rules into a new compound content.

Example:

```
element:before{
    content: "Hello!";
}
element:before{
    -oxy-prepend-content: "said: ";
}
element:before{
    -oxy-prepend-content: "I ";
}
```

The content shown before the `element` will be `I said: Hello!`.

Collapse Text: -oxy-collapse-text Property Value

Used to collapse the content of an element.

Oxygen XML Editor allows you to set the value of the `visibility` property to `-oxy-collapse-text`, meaning that the content of that element is not rendered. If an element is marked as `-oxy-collapse-text` you are not able to position the cursor inside it and edit it. The purpose of `-oxy-collapse-text` is to make the text value of an element editable only through a form control.

Example: *visibility* Property

The text value of an XML element will be edited using a text field form control. In this case, the text content is not directly present in the **Author** visual editing mode:

```
title{
 content: oxy_textfield(edit, '#text', columns, 40);
 visibility:-oxy-collapse-text;
}
```

Cyrillic Counters: -oxy-lower-cyrillic Property Values

Used to style lists with Cyrillic counters.

Oxygen XML Editor allows you to set the value of the `list-style-type` property to Cyrillic counters. For example, `-oxy-lower-cyrillic-ru`, `-oxy-lower-cyrillic-uk`, `-oxy-upper-cyrillic-ru` or `-oxy-upper-cyrillic-uk`, meaning that you can have Russian and Ukrainian counters.

Example: Cyrillic Counters

Counting list items with Cyrillic symbols:

```
li{
  display:list-item;
  list-style-type:-oxy-lower-cyrillic-ru;
}
```

Display Tag Markers: -oxy-display-tags Property

Used to specify whether or not tag markers are displayed.

Oxygen XML Editor allows you to choose whether tag markers of an element should never be presented or the current display mode should be respected. This is especially useful when working with `:before` and `:after` pseudo-elements, in which case the element range is already visually defined so the tag markers are redundant.

The property is named `-oxy-display-tags`, with the following possible values:

- **none** - Tags markers will not be presented regardless of the current display mode *(on page 604)*.
- **default** - The tag markers will be created depending on the current display mode *(on page 604)*.
- **inherit** - The value of the property is inherited from an ancestor element.

```
-oxy-display-tags
    Value: none | default | inherit
    Initial: default
    Applies to: all nodes(comments, elements, CDATA, etc.)
    Inherited: false
    Media: all
```

Example: *-oxy-display-tags* Property

In this example, the **para** element from DocBook uses a `:before` and `:after` element and its tag markers will not be visible.

```
para:before{
    content: "{";
}

para:after{
    content: "}";
}

para{
    -oxy-display-tags: none;
    display:block;
    margin: 0.5em 0;
}
```

Editable: -oxy-editable Property

Used to inhibit editing the content of a particular element.

If you want to inhibit the editing of the content of a certain element, you can set the `-oxy-editable` CSS property to `false` (the deprecated `editable` property is also supported).

Floating Toolbar: -oxy-floating-toolbar Property

Used to display a configured floating toolbar in **Author** mode.

The `-oxy-floating-toolbar` property is used to configure and display a floating toolbar in **Author** mode. It accepts a space-separated list of the following functions:

- `oxy_button`
- `oxy_buttonGroup`
- `oxy_textfield`
- `oxy_combobox`
- `oxy_label`

Note:
The `"|"` text value can be used to add a separator between elements of the toolbar.

It must be used in conjunction with the `-oxy-selected` and `-oxy-selection-inside` pseudo-classes. The `-oxy-selected` pseudo-class is automatically set on an element that is fully selected and the `-oxy-selection-inside` pseudo-class is automatically set on an element that has a selection inside.

Example 1:

```
p:-oxy-selection-inside {
    -oxy-floating-toolbar:
        oxy_button(actionID, 'bold')
        oxy_button(actionID, 'italic')
        oxy_button(actionID, 'underline')
}
```

This results in a floating toolbar that contains bold, italic, and underline actions presented in **Author** mode every time text inside a paragraph element is selected.

Example 2:

```
p:-oxy-selected {
    -oxy-floating-toolbar:
        oxy_label(text, "Platform: ")
        oxy_combobox(
            edit, '@platform',
            editable, false,
            values, 'windows, mac, linux',
            labels, 'Windows, MacOS, Linux'
            )
}
```

This results in a floating toolbar that contains a *Platform:* label and a drop-down menu used to change the value of the `@platform` profiling attribute. This is presented in **Author** mode every time a paragraph element is fully selected.

Example 3:

```
[conref]:-oxy-selected, [conkeyref]:-oxy-selected {
    -oxy-floating-toolbar:
        oxy_button(actionID, 'add_edit_content_reference')
        oxy_button(actionID, 'remove_content_reference')
        "|"
        oxy_button(actionID, 'conref.replace')
}
```

This results in a floating toolbar that contains **Edit Content Reference**, **Remove Content Reference**, and **Replace Reference with Content** actions presented in **Author** mode every time an element with a `@conref` or `@conkeyref` attribute is fully selected.

Folding Elements: -oxy-foldable / -oxy-folded / -oxy-not-foldable-child

Used to configure whether or not the content of an element can be expanded or collapsed.

Oxygen XML Editor allows you to declare some elements to be *foldable (on page 3420)*. This is especially useful when working with large documents organized in logical blocks, editing a large DocBook article or book, for instance. Oxygen XML Editor marks the *foldable* content with a small blue triangle. When you hover with your mouse pointer over this marker, a dotted line borders the collapsible content. The following actions are available in the **Folding** submenu of the contextual menu:

Toggle Fold

Toggles the state of the current fold.

Collapse Other Folds

Folds all the elements except the current element.

Collapse Child Folds

Folds the elements indented with one level inside the current element.

Expand Child Folds

Unfolds all child elements of the currently selected element.

Expand All

Unfolds all elements in the current document.

`-oxy-foldable` Property

This property defines whether or not the content for an element can be *folded* by the user. To define that an element's content can be *folded*, use the `-oxy-foldable:true` property.

`-oxy-folded` Property

This property is used in conjunction with the `-oxy-foldable` property and it defines the elements that are *folded* by default. To define an element to be *folded* by default, use the `-oxy-folded:true` property.

Note:
Since the `-oxy-folded` property works in conjunction with the `-oxy-foldable` property, the `-oxy-folded` property is ignored if the `-oxy-foldable` property is not set on the same element.

`-oxy-not-foldable-child` Property

When collapsing an element, it is useful to keep some of its content visible (for example, a short description of the collapsed region). The `-oxy-not-foldable-child` property is used to identify the child element that is

kept visible. As its value, it accepts an element name or a list of comma-separated element names. The first occurrence of each child element specified in the list of element names will be identified as the *not-foldable* child and displayed. If the element is marked as *foldable* (`-oxy-foldable:true;`) but it does not have the `-oxy-not-foldable-child` property or none of the specified *non-foldable* children exist, then the element is still *foldable*. In this case, the element kept visible when *folded* will be the `before` pseudo-element.

Example: Folding DocBook Elements

All the elements below can have a `<title>` child element and are considered to be logical sections. You mark them as being *foldable* leaving the `<title>` element visible.

```
set,
book,
part,
reference,
chapter,
preface,
article,
sect1,
sect2,
sect3,
sect4,
section,
appendix,
figure,
example,
table {
    -oxy-foldable:true;
    -oxy-not-foldable-child: title;
}
```

Note:
The `foldable`, `folded`, and `not-foldable-child` properties are deprecated and the equivalent with the `-oxy` prefix should be used instead.

Links: -oxy-link Property

Used to specify that a particular element should be considered a link.

Oxygen XML Editor allows you to declare some elements to be *links*. This is especially useful when working with many documents that reference each other. The links allow for an easy way to get from one document to another. Clicking the link marker will open the referenced resource in an editor.

To define the element that should be considered a link, you must use the `-oxy-link` property on the `:before` or `:after` pseudo-element. The value of the property indicates the location of the linked resource. Since links are usually indicated by the value of an attribute in most cases it will have a value similar to `attr(href)`

Example: DocBook Link Elements

The following elements are defined to be links on the `:before` pseudo-element and their values are defined by the value of an attribute.

```
*[href]:before{
    -oxy-link:attr(href);
    content: "Click " attr(href) " for opening" ;
}

ulink[url]:before{
    -oxy-link:attr(url);
    content: "Click to open: " attr(url);
}

olink[targetdoc]:before{
    -oxy-link: attr(targetdoc);
    content: "Click to open: " attr(targetdoc);
}
```

Link Navigation: -oxy-link-activation-trigger Property

Used to specify how hyperlinks are handled in **Author** mode.

The `-oxy-link-activation-trigger` property is used to specify when hyperlinks are clickable in **Author** mode. This is helpful for those who are used to the hyperlink activation procedure in other applications (for example, apps that use **Ctrl+Click** (**Command+Click** on macOS) to activate hyperlinks.

The possible values are:

- **click** - Hyperlinks are opened when a user mouse-clicks the link icon or text.
- **modifier-click** - Hyperlinks are opened when a user holds down **Ctrl** (**Command** on macOS) and mouse-clicks the link icon or text.
- **auto** - The hyperlink strategy is determined automatically, depending on the context.
- **inherit** - The value is inherited from the parent element.

Morph Elements: -oxy-morph Property Value

Used to specify that an element should be displayed inline.

Oxygen XML Editor allows you to specify that an element has an `-oxy-morph` display type (deprecated `morph` property is also supported), meaning that the element is *inline (on page 3420)* if all its children are *inline*.

Example: *-oxy-morph* Property Value

Suppose you have a *wrapper* XML element that allows users to set a number of attributes on all sub-elements. This element should have an *inline (on page 3420)* or *block (on page 3417)* behavior, depending on the behavior of its child elements:

```
wrapper{
 display:-oxy-morph;
}
```

Placeholders for Empty Elements: -oxy-placeholder-content Property

Used to configure placeholders for empty elements.

Oxygen XML Editor displays the element name as pseudo-content for empty elements if the **Show placeholders for empty elements** option *(on page 183)* is selected in the **Author** preferences page and there is no *before* or *after* content set in the CSS for this type of element. There are two CSS properties that can be used to control the placeholders (`-oxy-placeholder-content` and `-oxy-show-placeholder`).

`-oxy-placeholder-content` CSS Property

To control the displayed pseudo-content for empty elements, you can use the `-oxy-placeholder-content` CSS property.

The following example would change the `<keyword>` element to be displayed as `key`:

```
keyword{
    -oxy-placeholder-content:"key";
}
```

Note:
This CSS property accepts the **${i18n(key)}** *(on page 340)* localization editor variable, as in the following example:

```
-oxy-placeholder-content:"${i18n(id)}";
```

`-oxy-show-placeholder` CSS Property

The `-oxy-show-placeholder` property allows you to decide whether or not the placeholder will be shown. The possible values are:

- **always** - Always display placeholders.
- **default** - Always display placeholders if *before* or *after* content is not set in the CSS.
- **inherit** - The placeholders are displayed according to the **Show placeholders for empty elements** option *(on page 183)* (if *before* and *after* content is not declared).
- **no** - Never display placeholders.

Note:
Deprecated properties `show-placeholder` and `placeholder-content` are also supported.

Related information
Using Placeholders in Document Templates *(on page 387)*

Style Elements: -oxy-style Property

Used to configure the style of particular elements.

Oxygen XML Editor allows you to specify the style for an XML element. This is helpful if you want to embed CSS styling to XML elements directly in the XML file you are editing without having to edit the CSS files that are normally attached to the XML files. The property should have an XPath function for the value.

Example: *-oxy-style* Property

The following code snippet should be added in the CSS file that renders the files for your framework customization:

```
*{
   -oxy-style:attr(style);
}
```

Suppose you want to display the `<title>` elements in your XML document in the color red. You could add the following snippet directly in the XML document:

```
<title style="color:red;">My Memoirs</title>
```

Tip:
The `@style` attribute is supported by default in HTML5 documents.

Tags Color: -oxy-tags-color Property

Used to configure the background or foreground colors of tags.

By default, Oxygen XML Editor does not display element tags. You can use the **Partial Tags** button from the **Author** toolbar to control the amount of displayed markup *(on page 604)*.

To configure the default background and foreground colors of the tags, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Editor > Edit modes > Author**, and set the desired colors in the **Tags background color** *(on page 186)* and **Tags foreground color** *(on page 186)* options.

If you want to be more specific and configure the colors using a CSS, the `-oxy-tags-background-color` and `-oxy-tags-color` properties allow you to control the background and foreground colors for any particular XML element.

Example:

```
para {
    -oxy-tags-color:white;
    -oxy-tags-background-color:green;
}
title {
    -oxy-tags-color:yellow;
    -oxy-tags-background-color:black;
}
```

Custom CSS Functions

Oxygen XML Editor provides a wide range of custom CSS extension functions that can be used to customize the visual **Author** editing mode.

Arithmetic Functions

Arithmetic Functions that are supported.

You can use any of the arithmetic functions implemented in the *java.lang.Math* class (http://download.oracle.com/javase/6/docs/api/java/lang/Math.html).

In addition, the following functions are available:

Syntax	Details
oxy_add (*param1*, ... , *paramN*, *'returnType'*)	Adds the values of all parameters from *param1* to *paramN*.
oxy_subtract (*param1*, *param2*, ... , *paramN*, *'returnType'*)	Subtracts the values of parameters *param2* to *paramN* from *param1*.
oxy_multiply (*param1*, ... , *paramN*, *'return-Type'*)	Multiplies the values of parameters from *param1* to *paramN*.
oxy_divide (*param1*, *param2*, *'returnType'*)	Performs the division of *param1* to *param2*.
oxy_modulo (*param1*, *param2*, *'returnType'*)	Returns the reminder of the division of *param1* to *param2*.

Note:
The *returnType* can be *'integer'*, *'number'*, or any of the supported CSS measuring types.

Example: *oxy_multiply* Function

If you have an image with **width** and **height** specified on it, this will compute the number of pixels on it:

```
image:before{
 content: "Number of pixels: " oxy_multiply(attr(width), attr(height), "px");
}
```

Actions: oxy_action() Function

This function allows you to define actions directly in the CSS, rather than referencing them from the associated framework.

The `oxy_action()` function is frequently used from the *oxy_button()* function *(on page 2497)* that provides a graphical button for invoking a custom action. The action is normally defined in the associated Document Type (*framework* configuration) but the `oxy_action()` function allows you to define it directly in the CSS instead of the *framework* configuration.

The arguments received by the `oxy_action()` function are a list of properties that define an action. The following properties are supported:

- **name** - The name of the action. It will be displayed as the label for the button or menu item.
- **description** (optional) - A short description with details about the result of the action.
- **icon** (optional) - A path relative to the CSS pointing to an image (the icon for the action). The path can point to resources that are packed in Oxygen XML Editor (`oxygen.jar`) by starting its value with `/` (for example, `/images/Remove16.png`). It can also be expressed using an *editor variable (on page 332)*.
- **operation** - The name of the Java class implementing the *ro.sync.ecss.extensions.api.AuthorOperation* interface. There is also a variety of predefined operations *(on page 2269)* that can be used.

  > **Note:**
  > If the name of the operation specified in the CSS is not qualified (has no Java package name), then it is considered to be one of the built-in Oxygen XML Editor operations *(on page 2269)*. If the class is not found in this package, then it will be loaded using the specified name.

- **arg-<string>** - All arguments with the `arg-` prefix are passed to the operation (the string that follows the `arg-` prefix is passed). The argument value supports editor variables *(on page 332)*.
- **ID** - (optional) - The ID of the action from the *framework*. If this is specified, all others parameters are disregarded.

Example: *oxy_action* function inside an *oxy_button* form control *(on page 2497)*:

```
oxy_button(
   action, oxy_action(
            name, 'Insert',
            description, 'Insert an element after the current one',
            icon, url('insert.png'),
            operation,
             'InsertFragmentOperation',
            arg-fragment, '<element>${caret}</element>',
```

```
            arg-insertLocation, '.',
            arg-insertPosition, 'After'),
            showIcon, true)
```

Example: *oxy_action* Function

You can also create a button form control directly from an `oxy_action` function:

```
oxy_action(
            name, 'Insert',
            description, 'Insert an element after the current one',
            operation, 'InsertFragmentOperation',
            arg-fragment, '<element>${caret}</element>',
            arg-insertLocation, '.',
            arg-insertPosition, 'After')
```

Tip:
A code template is available to make it easy to add the `oxy_action` function with the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_action` code template.

Related information
Button Form Control *(on page 2497)*

Action Lists: oxy_action_list() Function

This function allows you to define a sequential list of actions directly in the CSS, rather than referencing them from the associated framework.

The `oxy_action_list()` function is used from the *oxy_buttonGroup()* function *(on page 2500)* that provides a graphical group of buttons with multiple custom actions. These actions are normally defined in the associated Document Type (*framework* configuration) but the `oxy_action_list()` function allows you to define the actions directly in the CSS instead of the *framework* configuration.

The arguments received by the `oxy_action_list()` function are a list of actions (executed sequentially) that are defined with the *oxy_action()* function *(on page 2473)*. The following properties are supported in the `oxy_action()` function:

- **name** - The name of the action. The name of the first defined action will be displayed as the label for the button or menu item.
- **description** (optional) - A short description with details about the result of the action. The description of the first defined action will be displayed in a tooltip.
- **icon** (optional) - A path relative to the CSS pointing to an image (the icon for the action). The path can point to resources that are packed in Oxygen XML Editor (`oxygen.jar`) by starting its value with `/` (for example, `/images/Remove16.png`). It can also be expressed using an *editor variable (on page 332)*.

- **operation** - The name of the Java class implementing the *ro.sync.ecss.extensions.api.AuthorOperation* interface. There is also a variety of predefined operations *(on page 2269)* that can be used.

  > **Note:**
  > If the name of the operation specified in the CSS is not qualified (has no Java package name), then it is considered to be one of the built-in Oxygen XML Editor operations *(on page 2269)*. If the class is not found in this package, then it will be loaded using the specified name.

- **arg-<string>** - All arguments with the `arg-` prefix are passed to the operation (the string that follows the `arg-` prefix is passed). The argument value supports editor variables *(on page 332)*.
- **ID** - (optional) - The ID of the action from the *framework*. If this is specified, all others parameters are disregarded.

Example: *oxy_action_list* Function

```
p:after {
    content: oxy_buttonGroup(
    label, 'A group of actions',
    icon, url('http://www.oxygenxml.com/img/icn_oxy20.png'),
    actions,
      oxy_action_list(
          oxy_action(
                name, 'Insert a new paragraph',
                description, 'Insert an element after the current one',
                operation, 'InsertFragmentOperation',
                arg-fragment, '<p></p>',
                arg-insertLocation, '.',
                arg-insertPosition, 'After'
          ),
          oxy_action(
                name, 'Delete',
                description, 'Deletes the current element',
                operation, 'DeleteElementOperation'
          )
      )
  )
}
```

> **Tip:**
> A code template is available to make it easy to add the `oxy_action_list` function with the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_action_list` code template.

Related information

Actions: oxy_action() Function *(on page 2473)*

Button Group Form Control *(on page 2500)*

Attributes Concatenation: oxy_attributes() Function

This function concatenates the attributes for an element and returns the serialization.

Syntax:

```
oxy_attributes ( )
```

Example: *oxy_attributes* Function

```
element{
  content:oxy_attributes();
}
```

For instance, if you have the following XML fragment: `<element att1="x" xmlns:a="2" x="&quot;"/>`, the CSS function will display:

```
att1="x" xmlns:a="2" x="""
```

Base URL: oxy_base-uri() Function

This function evaluates the base URL in the context of the current node.

It does not have any arguments and takes into account the `xml:base` context of the current node. See the XML Base specification for more details.

Example: *oxy_base-uri* Function

Suppose you have some image references but you want to see other thumbnail images that reside in the same folder (in **Author** mode):

```
image[href]{
 content:oxy_url(oxy_base-uri(), oxy_replace(attr(href),
    '.jpeg', 'Thumbnail.jpeg'));
}
```

Capitalization: oxy_capitalize() Function

This function capitalizes the first letter of the text received as argument.

Syntax:

```
oxy_capitalize ( text )
```

text

The text in which the first letter will be capitalized.

Example: *oxy_capitalize* Function

```
*:before{
  content: oxy_capitalize(oxy_name()) ": ";
}
```

This would insert the capitalized qualified name as static text content before the element.

Compound Actions: oxy_compound_action() Function

This function allows you to define multiple actions that will be executed sequentially.

The `oxy_compound_action()` function is used from the *oxy_button()* form control function *(on page 2497)* or the *oxy_buttonGroup()* form control function *(on page 2500)*.

The arguments received by the `oxy_compound_action()` function are a list of actions (executed sequentially) that are defined with the *oxy_action()* function *(on page 2473)*.

You can use three optional properties (`name`, `description`, `icon`) in the `oxy_compound_action()` function to provide labels for the compound action. If you do not specify these three properties, those same properties defined in the first *oxy_action* function will be used for the labels.

- **name** - The name of the action. It will be displayed as the label for the action. If you want to reuse the name of an action already defined in your framework, you can use the *oxy_getActionName* function.
- **description** - A short description with details about the result of the action. It will be displayed in a tooltip when hovering over the button linked to this action. If you want to reuse the description of an action already defined in your framework, you can use the *oxy_getActionDescription* function.
- **icon** - A path relative to the CSS pointing to an image (the icon for the action). The path can point to resources that are packed in Oxygen XML Editor (`oxygen.jar`) by starting its value with `/` (for example, `/images/Remove16.png`). It can also be expressed as an *editor variable (on page 332)*. If you want to reuse the icon of an action already defined in your framework, you can use the *oxy_getActionIcon* function.

The *oxy_getActionName*, *oxy_getActionDescription*, and *oxy_getActionIcon* functions accept the following 2 parameters:

- **framework.defined.action.id** (required) - The ID of an action defined in the current framework that gets the name, description, or icon for that action.
- **fallback** (optional) - A fallback value in case the ID value provided in the `framework.defined.action.id` parameter is not found.

Example: *oxy_compound_action* Function

```
oxy_button(
    action,
```

```
        oxy_compound_action(
        name, oxy_getActionName('framework.id', 'Fallback'),
        description, 'Inserts a paragraph and uses form controls to edit its @audience attribute',
        icon, url('http://www.oxygenxml.com/img/icn_oxy20.png'),
        oxy_action(
            name, 'Insert',
            description, 'Insert an element after the current one',
            operation, 'ro.sync.ecss.extensions.commons.operations.InsertFragmentOperation',
            icon, url('insert.png'),
            arg-fragment, "<p audience=''></p>",
            arg-insertLocation, '.',
            arg-insertPosition, 'After'
        ),
        oxy_action(
            name, 'Activate edit mode',
            description, 'Sets a pseudo class that will activate a CSS rule that will present a
 text field form control for the @audience attribute',
            operation, 'SetPseudoClassOperation',
            arg-name, 'edit-mode-on',
            arg-elementLocation, '.'
        )
        )
, showIcon, true)
```

Tip:
A code template is available to make it easy to add the `oxy_compound_action` function with the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_action_list` code template.

Related information

Actions: oxy_action() Function *(on page 2473)*

Button Form Control *(on page 2497)*

Concatenation: oxy_concat() Function

This function concatenates the received string arguments.

Syntax:

```
oxy_concat ( str_1 , str_2 )
```

str_1 ... str_n

The string arguments to be concatenated.

Example: *oxy_concat* Function

If an XML element has a `@padding-left` attribute:

```
<p padding-left="20">...
```

and you want to add a padding before it with that specific amount specified in the attribute value:

```
*[padding-left]{
 padding-left:oxy_concat(attr(padding-left), "px");
}
```

Get Text: oxy_getSomeText(text, length) Function

This function allows you to truncate a long string and to set a maximum number of displayed characters.

Syntax:

```
oxy_getSomeText ( text , length , endsWithPoints )
```

text

Displays the actual text.

length

Sets the maximum number of characters that are displayed.

endsWithPoints

Specifies if the truncated text ends with ellipsis.

Example: *oxy_getSomeText* Function

If an attribute value is very large, you can trim its content before it is displayed as static content:

```
*[longdesc]:before{
  content: oxy_getSomeText(attr(longdesc), 200);
}
```

Indexing: oxy_indexof() Function

This function is used to define searches.

The `oxy_indexof()` function has two signatures:

Syntax 1:

```
oxy_indexof ( text , toFind )
```

Returns the index within **text** string of the first occurrence of the **toFind** substring.

text

Text to search in.

toFind

The searched substring.

Syntax 2:

```
oxy_indexof ( text , toFind , fromOffset )
```

Returns the index within **text** string of the first occurrence of the **toFind** substring. The search starts from **fromOffset** index.

text

Text to search in.

toFind

The searched substring.

fromOffset

The index to start the search from.

Example: *oxy_indexof* Function

`oxy_indexof('abcd', 'bc')` returns 1.

`oxy_indexof('abcdbc', 'bc', 2)` returns 4.

If you only want to display part of an attribute value, for instance the part that comes before an **Appendix** string:

```
image[longdesc]{
 content: oxy_substring(attr(longdesc), 0,
          oxy_indexof(attr(longdesc), "Appendix"));
}
```

Label: oxy_label() Function

This function can be used in conjunction with the CSS `content` property to change the style of generated text.

The arguments of the function are *property name* - *property value* pairs. The following properties are supported:

- **text** - This property specifies the built-in form control you are using.
- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- **color** - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element that was used to insert it.

- **background-color** - Specifies the background color of the form control. If the value of the `background-color` property is `inherit`, the form control has the same color as the element that was used to insert it.
- **styles** - Specifies styles for the form control. The values of this property are a set of CSS properties:
  - **font-weight**, **font-size**, **font-style**, **font**
  - **text-align**, **text-decoration**
  - **width**
  - **color**, **background-color**
  - **link** - For more information about this property, see the *link* property section *(on page 2468)*.

```
element{
    content: oxy_label(text, "Label Text", styles,
      "font-size:2em;color:red;link:attr(href);");
}
```

Instead of using the values of the `styles` property individually, you can define them in a CSS file as in the following example:

```
* {
    width: 40%;
    text-align:center;
}
```

Then refer that file with an `@import` directive, as follows:

```
elem {
  content: oxy_label(text, 'my_label', styles, "@import 'labels.css';")
}
```

CAUTION:
Extensive use of the `styles` property may lead to performance issues.

If the text from an `oxy_label()` function contains new lines, for example `oxy_label(text, 'LINE1\A LINE2', width, 100px)`, the text is split in two. Each of the two new lines has the specified width of 100 pixels.

Note:
The text is split after `\A`, which represents a new line character.

You can use the `oxy_label()` function together with a built-in form control *(on page 2491)* function to create a form control based layouts.

Example: *oxy_label* Function

An example of a use case is if you have multiple attributes on a single element and you want use form controls on separate lines and style them differently. Consider the following CSS rule:

```
person:before {
  content: "Name:*" oxy_textfield(edit, '@name', columns, 20)
    "\A Address:" oxy_textfield(edit, '@address', columns, 20)
}
```

Suppose you only want the **Name** label to be set to **bold**, while you want both labels aligned to look like a table (the first column with labels and the second with a text field). To achieve this, you can use the `oxy_label()` to style each label differently.

```
person:before {
 content: oxy_label(text, "Name:*", styles, "font-weight:bold;width:200px")
          oxy_textfield(edit, '@name', columns, 20) "\A "
          oxy_label(text, "Address:", styles, "width:200px")
          oxy_textfield(edit, '@address', columns, 20)
}
```

Tip:
A code template is available to make it easy to add the `oxy_label` function with the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_label` code template.

Last Occurrence: oxy_lastindexof() Function

This function is used to define last occurrence searches.

The `oxy_lastindexof()` function has two signatures:

Syntax 1:

```
oxy_lastindexof ( text , toFind )
```

Returns the index within **text** string of the rightmost occurrence of the **toFind** substring.

text

Text to search in.

toFind

The searched substring.

Syntax 2:

```
oxy_lastindexof ( text , toFind , fromOffset )
```

The search starts from **fromOffset** index. Returns the index within **text** string of the last occurrence of the **toFind** substring, searching backwards starting from the **fromOffset** index.

text

Text to search in.

toFind

The searched substring.

fromOffset

The index to start the search backwards from.

Example: *oxy_lastindexof* Function

`oxy_lastindexof('abcdbc', 'bc')` returns 4.

`oxy_lastindexof('abcdbccdbc', 'bc', 2)` returns 1.

If you only want to display part of an attribute value, for instance the part that comes before an **Appendix** string:

```
image[longdesc]{
 content: oxy_substring(attr(longdesc), 0,
          oxy_lastindexof(attr(longdesc), "Appendix"));
}
```

Link Text: oxy_link-text() Function

You can use this function on the CSS `content` property to obtain a text description from the source of a reference.

By default, the `oxy_link-text()` function resolves DITA and DocBook references. For further details about how you can also extend this functionality to other *frameworks (on page 3420)*, go to Configuring an Extensions Bundle *(on page 2350)*.

DITA Support

For DITA, the `oxy_link-text()` function resolves the `<xref>` element and the elements that have a `@keyref` attribute. The text description is the same as the one presented in the final output for those elements. If you use this function for a `<topicref>` element that has the `@navtitle` and `@locktitle` attributes set, the function returns the value of the `@navtitle` attribute.

DocBook Support

For DocBook, the `oxy_link-text()` function resolves the `<xref>` element that defines a link in the same document. The text description is the same as the one presented in the final output for those elements.

Example: *oxy_link-text* Function

For the following XML and associated CSS fragments the `oxy_link-text()` function is resolved to the value of the `@xreflabel` attribute.

```
<para><code id="para.id" xreflabel="The reference label">my code</code>
      </para>
<para><xref linkend="para.id"/></para>
```

```
xref {
    content: oxy_link-text();
}
```

If the text from the target cannot be extracted (for instance, if the `@href` is not valid), you can use an optional argument to display fallback text.

```
*[class~="map/topicref"]:before{
    content: oxy_link-text("Cannot find the topic reference");
    link:attr(href);
}
```

Local Name: oxy_local-name() Function

This function evaluates the local name of the current node.

It does not have any arguments.

Example: *oxy_local-name* Function

To insert the local name as static text content before the element, use this CSS selector:

```
*:before{
  content: oxy_local-name() ": ";
}
```

Lowercase: oxy_lowercase() Function

This function transforms the text received as argument to lower case.

Syntax:

```
oxy_lowercase ( text )
```

text

The text to be lower cased.

Example: *oxy_lowercase* Function

To insert a lower-cased qualified name as static text content before the element, use this CSS selector:

```
*:before{
  content: oxy_lowercase(oxy_name()) ": ";
}
```

Name: oxy_name() Function

This function evaluates the qualified name of the current node.

It does not have any arguments.

Example: *oxy_name* Function

To insert a qualified name as static text content before the element, use this CSS selector:

```
*:before{
  content: oxy_name() ": ";
}
```

Parent URL: oxy_parent-url() Function

This function evaluates the parent URL of a URL received as string.

Syntax:

```
oxy_parent-url ( URL )
```

URL

The URL as string.

Replace: oxy_replace() Function

This function is used to replace a string of text.

The `oxy_replace()` function has two signatures:

Syntax 1:

```
oxy_replace ( text , target , replacement )
```

This function replaces each substring of the text that matches the literal target string with the specified literal replacement string.

text

The text in which the replace will occur.

target

The target string to be replaced.

replacement

The string replacement.

Example: Suppose that you have image references but you want to see other thumbnail images that reside in the same folder in the visual **Author** editing mode:

```
image[href]{
 content:oxy_url(oxy_base-uri(), oxy_replace(attr(href),
    '.jpeg', 'Thumbnail.jpeg'));
}
```

Syntax 2:

```
oxy_replace ( text , target , replacement , isRegExp )
```

This function replaces each substring of the text that matches the target string with the specified replacement string.

text

The text in which the replace will occur.

target

The target string to be replaced.

replacement

The string replacement.

isRegExp

If *true* the target and replacement arguments are considered regular expressions, if *false* they are considered literal strings.

Example: Suppose that you want to use a regular expression to replace all space sequences with an underscore:

```
image[title]{
 content:oxy_replace(attr(title), "\\s+", "_", true)
}
```

Substring of Text: oxy_substring() Function

This function is used to return a string of text.

The `oxy_substring()` function has two signatures:

Syntax 1:

```
oxy_substring ( text , startOffset )
```

Returns a new string that is a substring of the original **text** string. It begins with the character at the specified index and extends to the end of **text** string.

text

The original string.

startOffset

The beginning index, inclusive

Syntax 2:

```
substring ( text , startOffset , endOffset )
```

Returns a new string that is a substring of the original **text** string. The substring begins at the specified **startOffset** and extends to the character at index **endOffset** - 1.

text

The original string.

startOffset

The beginning index, inclusive.

endOffset

The ending index, exclusive.

Example: *oxy_substring* Function

`oxy_substring('abcd', 1)` returns the string `'bcd'`.

`oxy_substring('abcd', 4)` returns an empty string.

`oxy_substring('abcd', 1, 3)` returns the string `'bc'`.

If you only want to display part of an attribute value, for instance the part that comes before an **Appendix** string:

```
image[longdesc]{
 content: oxy_substring(attr(longdesc), 0,
          oxy_indexof(attr(longdesc), "Appendix"));
}
```

Unescape URL Value: oxy_unescapeURLValue(string) Function

This function returns the unescaped value of a URL-like string given as a parameter.

For example, if the value contains `%20` it will be converted to a simple space character.

Example: *oxy_unescapeURLValue* Function

`oxy_unescapeURLValue("http://www.example.com/a%20simple%20example.html")` returns the following value:

```
http://www.example.com/a simple example.html
```

Unparsed Entity URI: oxy_unparsed-entity-uri() Function

This function returns the URI value of an unparsed entity name.

Syntax:

```
oxy_unparsed-entity-uri ( unparsedEntityName )
```

unparsedEntityName

The name of an unparsed entity defined in the DTD.

This function can be useful to display images that are referenced with unparsed entity names.

Example: *oxy_unparsed-entity-uri* Function

CSS for displaying the image in Author for an *imagedata* with *entityref* to an unparsed entity:

```
imagedata[entityref]{
content: oxy_url(oxy_unparsed-entity-uri(attr(entityref)));
}
```

Uppercase: oxy_uppercase() Function

This function transforms the text received as argument to upper case.

Syntax:

```
oxy_uppercase ( text )
```

text

The text to be capitalized.

Example: *oxy_uppercase* Function

To insert the upper-cased qualified name as static text content before the element, use this CSS selector:

```
*:before{
  content: oxy_uppercase(oxy_name()) ": ";
}
```

URL: oxy_url() Function

This function extends the standard CSS `url()` function by allowing you to specify additional relative path components (parameters `loc_1` to `loc_n`).

Oxygen XML Editor uses all these parameters to construct an absolute location. Note that any of the parameters that are passed to the function can be either relative or absolute locations. These locations can be expressed as String objects, functions, or editor variables *(on page 332)* (built-in or custom).

Syntax:

```
oxy_url ( base_location , loc_1 , loc_2 )
```

base_location

String representing the base location. If not absolute, will be solved relative to the CSS file URL.

loc_1 ... loc_n (optional)

Strings representing relative location path components.

Examples: *oxy_url* Function

The following function receives String objects as input parameters:

```
oxy_url('http://www.oxygenxml.com/css/test.css', '../dir1/',
        'dir2/dir3/', '../../dir4/dir5/test.xml')
```

and returns:

```
'http://www.oxygenxml.com/dir1/dir4/dir5/test.xml'
```

The following function receives the result of the evaluation of two other functions as parameters (for instance, this is useful if you have image references and you want to see thumbnail images stored in the same folder):

```
image[href]{
 content:oxy_url(oxy_base-uri(), oxy_replace(attr(href),
    '.jpeg', 'Thumbnail.jpeg'));
}
```

The following function uses an editor variable *(on page 332)* as the first parameter to point to the Oxygen XML Editor installation location:

```
image[href] {
    content: oxy_url('${oxygenHome}', 'logo.png');
}
```

Related information

Editor Variables *(on page 332)*

XPath: oxy_xpath() Function

This function is used to evaluate XPath expressions.

Syntax:

```
oxy_xpath ( XPathExpression [, processChangeMarkers , value ] [, evaluate , value ])
```

It evaluates the given XPath 3.1 expression using the latest Saxon XSLT processor bundled with the application and returns the result. XPath expressions that depend on the cursor location can be successfully evaluated only when the cursor is located in the actual XML content.

The parameters of the function are as follows:

- A required `expression` parameter, which is the XPath expression to be evaluated.
- An optional `processChangeMarkers` parameter, followed by its value, which can be either `true` or `false` (default value). When you set the parameter to `true`, the function returns the resulting text with all the change markers accepted (*delete* changes are removed and *insert* changes are preserved).
- An optional `evaluate` parameter, followed by its value, which can be one of the following:
  - **dynamic** - Evaluates the XPath each time there is a change in the document. This is the default evaluation value.

    Important:
    If the edited XML document is large, using dynamic XPath evaluation may induce performance issues while editing the content.

  - **dynamic-once** - Separately evaluates the XPath for each node that matches the CSS selector. It will not re-evaluate the expression when changes are made to other nodes in the document. This will lead to improved performance, but the displayed content may not be updated to reflect the actual document content.
  - **static** - If the same XPath is evaluated on several nodes, the result for the first evaluation will be used for all other matches. Use this only if the XPath does not contain a relationship with the node on which the CSS property is evaluated. This will lead to improved performance, but the static displayed content may not be updated to reflect the actual document content.

When XPath expressions are evaluated, the entities and `<xi:include>` elements are replaced with the actual content that is referenced. For example, consider the following code snippet:

```
<article>
  <xi:include href="section1.xml" xmlns:xi="http://www.w3.org/2001/XInclude"/>
</article>
```

where `section1.xml` contains the following content:

```
<section>
  <p>Referenced content</p>
</section>
```

The XPath expression will be executed over the actual content in the `section1.xml` file.

Example: *oxy_xpath* Function

The following example counts the number of words from a paragraph (including *tracked changes (on page 3424)*) and displays the result in front of it:

```
para:before{
  content:
   concat("|Number of words:",
    oxy_xpath(
        "count(tokenize(normalize-space(string-join(text(), '')), ' '))",
        processChangeMarkers,
       true),
    "| ");
}
```

The `oxy_xpath()` function supports *editor variables (on page 332)*, as in the following example:

```
* {
    content:
    oxy_concat("Result: ",
        oxy_xpath('count(collection("${cfdu}/?select=*.xml"))')
    );
}
```

You can split the XPath expression on multiple lines by adding a backslash before each new line:

```
* {
    content: oxy_xpath('count(\
                    collection(\
                       "${cfdu}/?select=*.xml"))')
}
```

Form Controls

Oxygen XML Editor provides a variety of built-in form controls that allow users to interact with documents with familiar user interface objects. These form controls are defined in CSS stylesheets that are used to render **Author** mode. For customization purposes, Oxygen XML Editor also supports custom form controls in Java *(on page 2523)*.

How to Add a Built-in Form Control in Author Mode

Form controls can be added by defining them in the CSS associated with the XML document.

1. Create a custom CSS file.
2. Define the form control in the CSS using its dedicated CSS function. For example, to add a date picker form control *(on page 2508)*, its dedicated function is `oxy_datePicker`.
3. Associate the CSS file with the XML document in one of the following ways:

- If you have a framework (document type) already created for this XML vocabulary, create a CSS in the framework directory and associate the CSS with the framework *(on page 2262)*. This approach is recommended if you intend on sharing the customization with others.
- If you do not have a framework, you can associate the CSS to the XML document through a Processing Instruction *(on page 2425)*.

Editing Processing Instructions Using Form Controls *(on page 2525)*

Audio File Player Form Control

The `oxy_audio` built-in form control is used for providing a mechanism to play audio clips.

The `oxy_audio` form control supports the following properties:

- **href** - The absolute or relative location of a resource. This property is mandatory. Relative values are resolved relative to the CSS. If you have media resources relative to the XML document, you can specify their paths like this:

  ```
  oxy_audio(href, oxy_url(oxy_base-uri(), 'ex.mp3')), width, 400px)
  ```

- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units.

Example: *oxy_audio* Form Control

```
object {
    content:
        oxy_audio(
            href, 'resources/audio.mp3',
            width, 200px),
}
```

Tip:
To insert a sample of the `oxy_audio` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_audio` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]*`/samples/form-controls`.

Custom CSS Functions *(on page 2472)*
URL: oxy_url() Function *(on page 2488)*

Browser Form Control

The `oxy_browser` built-in form control is used for providing a mechanism to integrate HTML frames or interact with SVG documents directly in the **Author** mode editor. It can also be used to load HTML that executes JavaScript and from that JavaScript you can access the Oxygen XML Editor workspace.

The `oxy_browser` form control supports the following properties:

- **href** - The absolute or relative location of a resource. This property is mandatory. Relative values are resolved relative to the CSS. If you have media resources relative to the XML document, you can specify their paths like this:

  ```
  oxy_browser(href, oxy_url(oxy_base-uri(), 'ex.svg')), width, 50%, height, 50%)
  ```

- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units.
- **height** - Specifies the height of the form control area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units.

Example: *oxy_browser* Form Control

```
object {
  content:
    oxy_browser(
      href, 'http://example.page',
      width, 600px,
      height, 400px);
}
```

Tip:
To insert a sample of the `oxy_browser` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_browser` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]/samples/form-controls*.

Interacting with the Oxygen XML Editor Workspace

The `oxy_browser` form control also provides the possibility of creating custom form control without having to use the Java-based API. You can use the `oxy_browser` form control to load HTML that executes JavaScript. In the JavaScript, you can use some predefined global variables that provide a gateway between the JavaScript and the Oxygen XML Editor Java API. This allows you to perform changes in the document, open resources, and more, solely from the JavaScript.

Important:
This will only work if the loaded HTML is located inside a framework or plugin directory *(on page 147)*, such as: *[OXYGEN_INSTALL_DIR]/frameworks/* or *[OXYGEN_INSTALL_DIR]/plugins/*.

The following global variables can be used:

- **authorAccess** - This object is an instance of *ro.sync.ecss.extensions.api.AuthorAccess*.
- **contextElement** - An instance of ro.sync.ecss.extensions.api.node.AuthorNode. The form control is added over this node.
- **pluginWorkspace** - An instance of ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace.
- **fcArguments** - A `java.util.Map` implementation with the properties (name and value pairs) passed on the form control function.
- **apiHelper** - A helper object for creating Java objects. It allows you to create Java objects from within the JavaScript code. These objects can then be passed to the Java methods as in the following example:

```
var newAttrValue = apiHelper.newInstance(
          "ro.sync.ecss.extensions.api.node.AttrValue",
          ["normalizedValue", "rawValue", true]);
authorAccess.getDocumentController().setAttribute(
       "counter", newAttrValue, contextElement);
...
```

You can also specify the constructor signature:

```
var newAttrValue = apiHelper.newInstance(
        "ro.sync.ecss.extensions.api.node.AttrValue
        (java.lang.String, java.lang.String, boolean)",
        ["normalizedValue", "rawValue", true]);
authorAccess.getDocumentController().setAttribute(
        "counter", newAttrValue, contextElement);
...
```

For more information, open the `form-controls.xml` file in the ***[OXYGEN_INSTALL_DIR]*/samples/form-controls** directory and go to section **11.1 - Interacting with the Oxygen Workspace**.

Warning:
On macOS, you need to use asynchronous calls to the API, due to the following JDK bug: https://bugs.openjdk.java.net/browse/JDK-8087465. By default, the API is called synchronously, but you can change this behavior for each API object by calling two methods: `sync()` and `async()`.

```
// By default, the methods are invoke synchronously.
var ctrl = authorAccess.getDocumentController();
try {
  // On Mac, methods that change the document must be executed asynchronously.
  ctrl.async();
  ctrl.setAttribute("counter", newAttrValue, contextElement);
} finally {
  ctrl.sync();
}
```

Listening for Changes in the Document

If the form control presents some information from the document (for example, the value of an attribute), then it needs to be notified on changes in the document so that it can update that information. To do this, follow these steps:

1. In the JavaScript, the `bridgeReady()` method is invoked as soon as the form control is loaded and the API bridge is installed. This is where you can add a listener:

```
function bridgeReady () {
  // We declare a member function for each method of the
  // ro.sync.ecss.extensions.api.AuthorListener interface (same function signature)
  var handler = {
    attributeChanged : function(event) {
      var node = event.getOwnerAuthorNode();
      var attrName = event.getAttributeName();

      if (node.equals(contextElement) && attrName === "counter") {
```

```
        init();
      }
    },
    contentDeleted : function(event) {},
    contentInserted : function(event) {}
  };

  // We create a proxy over an ro.sync.ecss.extensions.api.AuthorListener that will
  // delegate its methods to the JS object's functions.
  // We assign the listener to a global variable so that we can remove it later on,
  // on the dispose() method.
  authorDocumentListener = apiHelper.createProxyListener(
      "ro.sync.ecss.extensions.api.AuthorListener", handler);

  var ctrl = authorAccess.getDocumentController();

  // Add the proxy listener.
  ctrl.addAuthorListener(authorDocumentListener);
}
```

2. Since a listener was added on the document, it is important to remove it once the form control is not used anymore. When a form control is discarded, the `dispose()` JavaScript function is invoked, so if you have any cleanup to do, make sure you define a function with this name and remove any previously created listeners in it.

```
/**
 * The form control will not be used anymore. Clean up.
 */
function dispose() {
  // Dispose all added listeners.
  var ctrl = authorAccess.getDocumentController();
  ctrl.removeAuthorListener(authorDocumentListener);
}
```

Debugging JavaScript Used for Custom Form Controls

If you encounter unexpected results when using the method described above *(on page 2494)*, you can debug the script by using the following guidelines:

- Calls to `alert("message.to.present")` or `console.log("message.to.present")` will be presented in the Results panel *(on page 558)*.
- You can install the **Firebug** extension by executing the following script:

```
{code:javascript}
function installFB() {
```

```
  if (!document.getElementById('FirebugLite')) {
    E = document['createElement' + 'NS'] && document.documentElement.namespaceURI;
    E = E ? document['createElement' + 'NS'](E, 'script')
          : document['createElement']('script');
    E['setAttribute']('id', 'FirebugLite');
    E['setAttribute']('src',
                      'https://getfirebug.com/' + 'firebug-lite.js' + '#startOpened');
    E['setAttribute']('FirebugLite', '4');
    (document['getElementsByTagName']('head')[0]
          || document['getElementsByTagName']('body')[0]).appendChild(E);
    E = new Image;
    E['setAttribute']('src', 'https://getfirebug.com/' + '#startOpened');
  }
}
{code}
```

Note:
To force the *Browser Form Control* to reload after making changes to the JavaScript file, you need to use the **Reload page** action from the form control's contextual menu.

Custom CSS Functions *(on page 2472)*
URL: oxy_url() Function *(on page 2488)*

Button Form Control

The `oxy_button` built-in form control is used for graphical user interface objects that invoke a custom **Author** mode action (defined in the associated Document Type) referencing it by its ID, or directly in the CSS.

The `oxy_button` form control supports the following properties:

- **fontInherit** - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- **color** - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element that was used to insert it.

- **visible** - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- **transparent** - Flattens the aspect of the button form control, removing its border and background. The values of this property can be `true` or `false` (default value).
- **showText** - Specifies if the action text should be displayed on the button form control. If this property is missing then the button displays the icon only if it is available, or the text if the icon is not available. The values of this property can be `true` or `false`.

```
element {
  content: oxy_button(actionID, 'remove.attribute', showText, true);
}
```

- **showIcon** - Specifies if the action icon should be displayed on the button form control. If this property is missing then the button displays the icon only if it is available, or the text if the icon is not available. The values of this property can be `true` or `false`.

```
element {
  content: oxy_button(actionID, 'remove.attribute', showIcon, true);
}
```

- **enableInReadOnlyContext** - To enable button form controls *(on page 2497)* or groups of buttons form controls *(on page 2500)*, this property needs to be set to `true`. This property can be used to specify areas as *read-only* (by setting the `-oxy-editable` property to `false`). This is useful when you want to use an action that does not modify the context.
- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_button(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

- **actionContext** - Specifies the context that the action associated with the form control is executed. Its possible values are `element` (default value) and `caret`. If you select the `element` value, the context is the element that holds the form control. If you select the `caret` value, the action is invoked at the cursor location. If the cursor is not inside the element that holds the form control, the `element` value is selected automatically.
- **actionID** - The ID of the action, specified in the *document type association (on page 155)*, that is invoked when you click the button.

Note:
The element that contains the form control represents the context where the action is invoked.

- **action** - Defines an action directly, rather than using the `actionID` parameter to reference an action from the *document type association (on page 155)*. This property is defined using the *oxy_action* function *(on page 2473)*.

  > **Tip:**
  > You can also create a button form control directly from an *oxy_action* function *(on page 2474)*.

```
oxy_button(action, oxy_action(
          name, 'Insert',
          description, 'Insert an element after the current one',
          icon, url('insert.png'),
          operation, 'InsertFragmentOperation',
          arg-fragment, '<element>${caret}</element>',
          arg-insertLocation, '.',
          arg-insertPosition, 'After'
))
```

  > **Tip:**
  > To execute multiple actions sequentially, you can use the *oxy_compound_action* function *(on page 2477)*.

Example: *oxy_button* Form Control

```
button:before {
  content: "Label:"
     oxy_button(
         /* This action is declared in the document type
            associated with the XML document. */
         actionID, "insert.popupWithMultipleSelection");
}
```

> **Tip:**
> To insert a sample of the `oxy_button` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_button` code template. Also, an `oxy_button_in_place_action` code template is available that inserts an `oxy_button` function that includes an `action` parameter.
>
> To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]*`/samples/form-controls`.

Custom CSS Functions *(on page 2472)*

Actions: oxy_action() Function *(on page 2473)*

Button Group Form Control

The `oxy_buttonGroup` built-in form control is used for a graphical user interface group of buttons that invokes one of several custom **Author** mode actions (defined in the associated Document Type) referencing it by its ID, or directly in the CSS.

The `oxy_buttonGroup` form control supports the following properties:

- **label** - Specifies the label to be displayed on the button. This label can be translated using the *${i18n()}* editor variable *(on page 340)*.
- **icon** - The path to the icon to be displayed on the button.
- **visible** - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- **tooltip** - Specifies a tooltip to be displayed when you hover over the form control.
- **transparent** - Makes the button transparent without any borders or background colors. The values of this property can be `true` or `false`.
- **fontInherit** - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- **enableInReadOnlyContext** - To enable button form controls *(on page 2497)* or groups of buttons form controls *(on page 2500)*, this property needs to be set to `true`. This property can be used to specify areas as *read-only* (by setting the `-oxy-editable` property to `false`). This is useful when you want to use an action that does not modify the context.
- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_buttonGroup(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

- **actionIDs** - The IDs of the actions that will be presented in the group of buttons.

- **actionID** - The ID of the action, specified in the *document type association (on page 155)*, that is invoked when you click the button.

> **Note:**
> The element that contains the form control represents the context where the action is invoked.

- **actions** - Defines a sequential list of actions directly, rather than using the `actionID` parameter to reference actions from the *document type association (on page 155)*. This property is defined using the *oxy_action_list* function *(on page 2474)*.

```
oxy_buttonGroup(
    label, 'A group of actions',
    icon, url('http://www.oxygenxml.com/img/icn_oxy20.png'),
    actions,
      oxy_action_list(
          oxy_action(
                name, 'Insert',
                description, 'Insert an element after the current one',
                operation, 'InsertFragmentOperation',
                arg-fragment, '<element></element>',
                arg-insertLocation, '.',
                arg-insertPosition, 'After'
          ),
          oxy_action(
                name, 'Delete',
                description, 'Deletes the current element',
                operation, 'DeleteElementOperation'
          )
      )
  )
```

> **Tip:**
> To execute multiple actions sequentially, you can use the *oxy_compound_action* function *(on page 2477)* in the `oxy_action_list` function *(on page 2474)*.
>
> ```
> p:before {
> content:
>   oxy_buttonGroup(
>    label, 'A group of actions',
>     icon, url('http://www.oxygenxml.com/img/icn_oxy20.png'),
>     actions,
>       oxy_action_list(
>             oxy_compound_action(
> ```

```
                name, oxy_getActionName('framework.id', 'Fallback'),
                description, 'Inserts a paragraph and uses form controls to edit its
@audience attribute',
                icon, url('http://www.oxygenxml.com/img/icn_oxy20.png'),
                oxy_action(
                  name, 'Insert',
                  description, 'Insert an element after the current one',

operation, 'ro.sync.ecss.extensions.commons.operations.InsertFragmentOperation',
                  icon, url('insert.png'),
                  arg-fragment, "<p audience=''></p>",
                  arg-insertLocation, '.',
                  arg-insertPosition, 'After'
                ),
                oxy_action(
                  name, 'Activate edit mode',
                  description, 'Sets a pseudo class that will activate a CSS rule
that will present a text field form control for the @audience attribute',
                  operation, 'SetPseudoClassOperation',
                  arg-name, 'edit-mode-on',
                  arg-elementLocation , '.'
                )
       ),
         oxy_action(
               name, 'Delete',
               description, 'Deletes the current element',
               operation, 'DeleteElementOperation'
         )
     )
  )
}
```

- **actionContext** - Specifies the context that the action associated with the form control is executed. Its possible values are `element` (default value) and `caret`. If you select the `element` value, the context is the element that holds the form control. If you select the `caret` value, the action is invoked at the cursor location. If the cursor is not inside the element that holds the form control, the `element` value is selected automatically.
- **actionStyle** - Specifies what to display for an action in the form control. The values of this property can be `text` (default value), `icon`, or `both`.

Example: *oxy_buttonGroup* Form Control

```
buttongroup:before {
  content:
    oxy_label(text, "Button Group:", width, 150px, text-align, left)
    oxy_buttonGroup(
       label, 'A group of actions',
       /* The action IDs are declared in the document type
          associated with the XML document. */
       actionIDs,
          "insert.popupWithMultipleSelection,insert.popupWithSingleSelection",
       actionStyle, "both");
}
```

Tip:
To insert a sample of the `oxy_buttonGroup` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_buttonGroup` code template. Also, an `oxy_buttonGroup_in_place_action` code template is available that inserts an `oxy_buttonGroup` function that includes an `oxy_action_list` function.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]*`/samples/form-controls`.

Checkbox Form Control

The `oxy_checkbox` built-in form control is used for a graphical user interface box that you can click to enable or disable an option. A single checkbox or multiple checkboxes can be used to present and edit the value on an attribute or element.

The `oxy_checkbox` form control supports the following properties:

- **edit** - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName (on page 3423)* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note:
    You can set the value of the `visibility` property to `-oxy-collapse-text` *(on page 2463)* to render the text only in the form control that the `oxy_editor` function specifies.

- **resultSeparator** - If multiple check-boxes are used, the separator is used to compose the final result. If not specified, the *space* character is used.
- **tooltips** - Associates tooltips to each value in the `values` property. The value of this property is a list of tooltip messages separated by commas. If you want the tooltip to display a comma, use the `${comma}` variable *(on page 339)*.
- **visible** - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- **values** - Specifies the values that are committed when the check-boxes are selected. If these values are not specified in the CSS, they are collected from the associated XML Schema.

  Note:
  Typically, when you use a comma in the values of a form control, the content that follows a comma is considered a new value. If you want to include a comma in the values, precede the comma with two backslashes. For example, `(values, '1\\, 2\\, 3, 4, edit, false)` will display a form control that has **1, 2, 3** for the first value and **4** for the second value.

- **fontInherit** - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`..
- **uncheckedValues** - Specifies the values that are committed when check-boxes are not selected.
- **labels** - This property must have the same number of items as the `values` property. Each item provides a literal description of the items listed in the `values` property. These labels can be translated using the *${i18n()}* editor variable *(on page 340)*.. If this property is not specified, the `values` property is used as the label.
- **columns** - Controls the layout of the form control. The check boxes will be grouped in a number of columns equal to the given value.
- **color** - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element that was used to insert it.
- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_checkbox(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: Single *oxy_checkbox* Form Control

```
checkBox[attribute]:before {
    content: "A check box editor that edits a two valued attribute (On/Off)
              The values are specified in the CSS:"
        oxy_checkbox(
        edit, "@attribute",
        values, "On",
        uncheckedValues, "Off",
        labels, "On/Off");
}
```

Example: Multiple *oxy_checkbox* Form Controls

```
multipleCheckBox[attribute]:before {
    content: "Multiple checkboxes editor that edits an attribute value.
              Depending whether the check-box is selected,
              a different value is committed:"
        oxy_checkbox(
        edit, "@attribute",
        values, "true, yes, on",
        uncheckedValues, "false, no, off",
        resultSeparator, ","
        labels, "Present, Working, Started");
}
```

Tip:
To insert a sample of the `oxy_checkbox` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_checkbox` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]*`/samples/form-controls`.

Combo Box Form Control

The `oxy_combobox` built-in form control is used for providing a graphical user interface object that is a drop-down menu of proposed values. This form control can also be used for a combination of a drop-down menu and an editable single-line text field.

The `oxy_combobox` form control supports the following properties:

- **edit** - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName (on page 3423)* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note:
    You can set the value of the `visibility` property to `-oxy-collapse-text` *(on page 2463)* to render the text only in the form control that the `oxy_editor` function specifies.
- **columns** - Controls the width of the form control. The unit size is the width of the **w** character.
- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- **visible** - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- **editable** - This property accepts the **true** and **false** values. In addition to a drop-down menu, the **true** value also generates an editable text field box that allows you to insert other values than the proposed ones. The **false** value generates a drop-down menu that only accepts the proposed values.
- **tooltips** - Associates tooltips to each value in the `values` property. The value of this property is a list of tooltip messages separated by commas. If you want the tooltip to display a comma, use the `${comma}` variable *(on page 339)*.
- **values** - Specifies the values that populate the list of proposals. If these values are not specified in the CSS, they are collected from the associated XML Schema..

Note:
Typically, when you use a comma in the values of a form control, the content that follows a comma is considered a new value. If you want to include a comma in the values, precede the comma with two backslashes. For example, `(values, '1\\, 2\\, 3, 4, edit, false)` will display a form control that has **1, 2, 3** for the first value and **4** for the second value.

- **fontInherit** - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- **labels** - This property must have the same number of items as the `values` property. Each item provides a literal description of the items listed in the `values` property. These labels can be translated using the *${i18n()}* editor variable *(on page 340)*.

Note:
This property is only available for read-only combo boxes (the `editable` property is set to `false`).

- **color** - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element that was used to insert it.
- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_combobox(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

- **canRemoveValue** - If the value is set to `true` and the combo box is not editable, then a new `<Empty>` value is added in that combo box. This clears or removes the value being edited, depending on if it edits an element or attribute.
- **onChange** - Can be used to invoke an action when the value of the combo box changes. The action can be created in the CSS using the `oxy_action()` function *(on page 2473)* or referenced from the *framework (on page 3420)* by its ID. After the action is executed, the cursor remains in the combo box. Note that this property does not support actions defined by JavaScript code.

Example: *oxy_combobox* Form Control

This example uses a combo box form control to edit an attribute value. Each time the value changes, it triggers an action that inserts an element into the attribute's parent element.

```
comboBox:before {
    content: "A combo box that edits an attribute value.
              The possible values are provided from CSS:"
        oxy_combobox(
            edit, "@attribute",
            editable, false,
            values, "value1, value2, value3",
            labels, "Value no1, Value no2, Value no3",
            onChange, oxy_action(
                name, 'Insert',
                operation, 'XQueryUpdateOperation',
                arg-script, 'insert node <product>{xs:string(@attribute)}</product>
                          as last into .'));
}
```

Tip:

To insert a sample of the `oxy_combobox` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_combobox` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]*`/samples/form-controls`.

Date Picker Form Control

The `oxy_datePicker` built-in form control is used for offering a text field with a calendar browser that allows the user to choose a certain date in a specified format.

The `oxy_datePicker` form control supports the following properties:

- **edit** - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName (on page 3423)* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

  > **Note:**
  > You can set the value of the `visibility` property to `-oxy-collapse-text` *(on page 2463)* to render the text only in the form control that the `oxy_editor` function specifies.

- **columns** - Controls the width of the form control. The unit size is the width of the **w** character.
- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- **color** - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element that was used to insert it.
- **fontInherit** - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- **format** - This property specifies the format of the inserted date, if a specific format is not detected from the associated document schema. The pattern value must be a valid Java date (or date-time) format. If this property is missing, the format of the date is determined from the associated schema.
- **visible** - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- **validateInput** - Specifies if the form control is validated. If you introduce a date that does not respect the format, the `datePicker` form control is rendered with a red foreground. By default, the input is validated. To disable the validation, set this property to `false`.
- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_datePicker(edit, "@attribute", hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: *oxy_datePicker* Form Control

```
date {
    content:
        oxy_label(text, "Date time attribute with
```

```
                    format defined in CSS: ", width, 300px)
        oxy_datePicker(
            columns, 16,
            edit, "@attribute",
            format, "yyyy-MM-dd");
}
```

Tip:
To insert a sample of the `oxy_datePicker` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_datePicker` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]/samples/form-controls*.

Custom CSS Functions *(on page 2472)*
Label: oxy_label() Function *(on page 2480)*

HTML Content Form Control

The `oxy_htmlContent` built-in form control is used for rendering HTML content. This HTML content is displayed as a graphical element shaped as a box. The shape of the box is determined by a given width and the height is computed based upon the length of the text.

The `oxy_htmlContent` form control supports the following properties:

- **href** - The absolute or relative location of a resource. The resource needs to be a well-formed HTML file.
- **id** - The unique identifier of an item. This is a `<div>` element that has a unique `@id` and is a child of the `<body>` element. The `<div>` element is the container of the HTML content to be rendered by the form control.
- **content** - An alternative to the `@href` and `@id` pair of elements. It provides the HTML content that will be displayed in the form control.
- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).

- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_htmlContent(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

You can customize the style of the content using CSS that is either referenced by the file identified by the `href` property or is defined inline. If you change the HTML content or CSS and you want your changes to be reflected in the XML that renders the form control, then you need to refresh the XML file. If the HTML does not have an associated style, then a default text and background color will be applied.

Example: *oxy_htmlContent* Form Control

In the following example, the form control collects the content from the `p_description` `<div>` element found in the `descriptions.html` file. The box is 400 pixels wide and is displayed before a paragraph identified by the `@intro_id` attribute value.

```
p#intro_id:before {
    content:
        oxy_htmlContent(
            href, "descriptions.html",
            id, "p_description",
            width, 400px);
}
```

An alternative example, using the `content` property:

```
p#intro_id:before {
    content:
        oxy_htmlContent(
            content, "<div style='font-weight:bold;'>My content</div>",
            width, 400px);
}
```

Tip:
To insert a sample of the `oxy_htmlContent` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_htmlContent` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]/samples/form-controls*.

https://www.youtube.com/embed/-WY3wzkMSLM

Related information

Custom CSS Functions *(on page 2472)*

Pop-up Form Control

The `oxy_popup` built-in form control is used to offer a contextual menu that provides quick access to various actions. A pop-up form control can display single or multiple selections.

The `oxy_popup` form control supports the following properties:

- **color** - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element that was used to insert it.

  Note:
  This property is used for rendering in the **Author** mode.

- **columns** - Controls the width of the form control. The unit size is the width of the **w** character. This property is used for the visual representation of the form control.
- **edit** - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName (on page 3423)* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note:
    You can set the value of the `visibility` property to `-oxy-collapse-text` *(on page 2463)* to render the text only in the form control that the `oxy_editor` function specifies.

- **editorSort** - Specifies the sorting of the values displayed after clicking the popup control (for example, clicking a drop-down arrow button). The possible values of this property are `ascending` and `descending`.

- **fontInherit** - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_popup(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

- **labels** - Specifies the label associated with each entry used for presentation. If this property is not specified, the **values** property is used instead.
- **rendererSeparator** - Defines a separator used when multiple values are rendered. If not specified, the value of the `resultSeparator` property is used.
- **rendererSort** - Specifies the sorting of the values (labels) displayed on the form control before clicking the popup control. The possible values of this property are `ascending` and `descending`.
- **resultSeparator** - If multiple check-boxes are used, the separator is used to compose the final result. If not specified, the *space* character is used.

> **Note:**
> The value of the `resultSeparator` property cannot exceed one character.

- **rows** - This property specifies the number of rows that the form control presents.

> **Note:**
> If the value of the **rows** property is not specified, the default value of **12** is used.

- **selectionMode** - Specifies whether the form control allows the selection of a single value or multiple values. The predefined values of this property are `single` (default value) and `multiple`.
- **sort** - Specifies the default sorting of the form control values (the values displayed before and after clicking the popup control). However, the `editorSort` and `rendererSort` properties have a higher priority. The possible values of this property are `ascending` and `descending`.
- **tooltip** - Specifies a tooltip to be displayed when you hover over the form control.
- **tooltips** - Associates tooltips to each value in the `values` property. The value of this property is a list of tooltip messages separated by commas. If you want the tooltip to display a comma, use the `${comma}` variable *(on page 339)*.

  Example:

```
link:before{
 content: oxy_popup(
         edit, '@href',
         values, "Spring, Summer, Autumn, Winter",
         tooltips, "Iris${comma}Snowdrop, Gardenia${comma}Liliac,
             Chrysanthemum${comma}Salvia, Gerbera",
        selectionMode, single);
}
```

- **values** - Specifies the values that populate the list of proposals. If these values are not specified in the CSS, they are collected from the associated XML Schema.

  Note:
  Typically, when you use a comma in the values of a form control, the content that follows a comma is considered a new value. If you want to include a comma in the values, precede the comma with two backslashes. For example, `(values, '1\\, 2\\, 3, 4, edit, false)` will display a form control that has **1, 2, 3** for the first value and **4** for the second value.

- **visible** - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).

Example: *oxy_popup* Form Control

```
popupWithMultipleSelection:before {
    content: " This editor edits an attribute value.
                The possible values are specified
    inside the CSS: "
        oxy_popup(
            edit, "@attribute",
            values, "value1, value2, value3, value4, value5",
            labels, "Value no1, Value no2, Value no3, Value no4, Value no5",
            resultSeparator, "|",
            columns, 10,
            selectionMode, "multiple",
            color, "blue",
            fontInherit, true);
    font-size:30px;
}
```

Tip:
To insert a sample of the `oxy_popup` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_popup` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]/samples/form-controls*.

Text Area Form Control

The `oxy_textArea` built-in form control is used for entering multiple lines of text in a graphical user interface box. A text area may include optional syntax highlight capabilities to present the form control.

The `oxy_textArea` form control supports the following properties:

- **edit** - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName (on page 3423)* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note:
    You can set the value of the `visibility` property to `-oxy-collapse-text` *(on page 2463)* to render the text only in the form control that the `oxy_editor` function specifies.

  - **#content** - This parameter is useful when an element has mixed or element-only content and you want to edit its content inside a text area form control.

    For example, if you have the following XML content:

```
<codeblock outputclass="language-xml">START_TEXT<ph>phase</ph>
          <apiname><text>API</text></apiname></codeblock>
```

and your CSS includes the following snippet:

```
codeblock:before{
content:
    oxy_textArea(
      edit, '#content',
      contentType, 'text/xml');
}
```

then the text area form control will edit the following fragment:

```
START_TEXT<ph>phase</ph><apiname><text>API</text></apiname>
```

Note:
When the value of the `edit` property is `#content`, the text area form control will also offer content completion proposals

- **columns** - Controls the width of the form control. The unit size is the width of the **w** character.
- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- **fontInherit** - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- **visible** - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- **rows** - This property specifies the number of rows that the form control presents. If the form control has more lines, you can scroll and see them all.
- **contentType** - Specifies the type of content that the form control will format with syntax highlighting. The following values are supported: `text/batch; text/c; text/cc; text/css; text/dtd; text/html; text/java; text/javascript; text/json; text/markdown; text/nvdl; text/perl; text/plain; text/php; text/properties; text/python; text/rnc; text/rng; text/sch; text/shell; text/sql; text/wsdl; text/xml; text/xpath; text/xproc; text/xquery; text/xsd; text/xsl; text/yaml.`
- **indentOnTab** - Specifies the behavior of the **Tab** key. If the value of this property is set to `true` (default value), the **Tab** key inserts characters. If it is set to `false`, **Tab** is used for navigation, jumping to the next editable position in the document.
- **white-space** - CSS property that influences the value that you edit, as well as the form control size:
  - **pre** - The whitespaces and new lines of the value are preserved and edited. If the `rows` and `columns` properties are not specifies, the form control calculates its size on its own so that all the text is visible.
  - **pre-wrap** - The long lines are wrapped to avoid horizontal scrolling.

> **Note:**
> The `rows` and `columns` properties must be specified. If these are not specified, the form control considers the value to be `pre`.

    - **normal** - The white spaces and new lines are normalized.
- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_textArea(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: *oxy_textArea* Form Control

The following example presents a text area with CSS syntax highlighting that calculates its own dimension, and a second one with XML syntax highlighting with defined dimension.

```
textArea {
    visibility: -oxy-collapse-text;
    white-space: pre;
}

textArea[language="CSS"]:before {
    content: oxy_textArea(
      edit, '#text',
      contentType, 'text/css');
}

textArea[language="XML"]:before {
    content: oxy_textArea(
      edit, '#text',
      contentType, 'text/xml',
      rows, 10,
      columns, 30);
}
```

Tip:
To insert a sample of the `oxy_textArea` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_textArea` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]/samples/form-controls*.

Text Field Form Control

The `oxy_textfield` built-in form control is used for entering a single line of text in a graphical user interface box. A text field may include optional content completion capabilities, used to present and edit the value of an attribute or an element.

The `oxy_textfield` form control supports the following properties:

- **edit** - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName (on page 3423)* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

  Note:
  You can set the value of the `visibility` property to `-oxy-collapse-text` *(on page 2463)* to render the text only in the form control that the `oxy_editor` function specifies.

- **columns** - Controls the width of the form control. The unit size is the width of the **w** character.
- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- **fontInherit** - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.

- **visible** - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- **values** - Specifies the values that populate the list of proposals. If these values are not specified in the CSS, they are collected from the associated XML Schema.
- **tooltips** - Associates tooltips to each value in the `values` property. The value of this property is a list of tooltip messages separated by commas. If you want the tooltip to display a comma, use the `${comma}` variable *(on page 339)*.
- **tooltip** - Specifies a tooltip to be displayed when you hover over the form control.
- **color** - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element that was used to insert it.
- **hasMultipleValues** - Specifies if the text field allows multiple values separated by spaces or just a single value.

  Note:
  If the value is `false`, the *Content Completion Assistant* *(on page 3418)* considers the entire text as the prefix for its proposals. If the value is `true` (the default value), the space is the delimiter for the values and thus it is not included in the prefix (the prefix will be whatever comes after the space).

  For example, suppose the possible values for your text field are: `value a`, `value b`, and `other values`. If the `hasMultipleValues` property is set to `true` and the user enters `"value "` (notice the space character after 'value') in the text field, the *Content Completion Assistant* will suggest all three values because the prefix is whatever comes after the space, and in this case the user did not enter anything after the space. If the `hasMultipleValues` property was set to `false`, the *Content Completion Assistant* would only suggest `value a` and `value b` because the space is considered part of the prefix.

- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_textfield(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: *oxy_textfield* Form Control

```
element {
    content: "Label: "
        oxy_textfield(
            edit, "@my_attr",
```

```
            values, "value1, value2",
            color, "red",
            columns, 40);
}
```

Tip:
To insert a sample of the `oxy_textfield` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_textfield` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]*`/samples/form-controls`.

URL Chooser Form Control

The `oxy_urlChooser` built-in form control is used for a dialog box that allows you to select the location of local or remote resources. The inserted reference is made relative to the URL of the currently open editor.

The `oxy_urlChooser` editor supports the following properties:

- **edit** - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName (on page 3423)* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note:
    You can set the value of the `visibility` property to `-oxy-collapse-text` *(on page 2463)* to render the text only in the form control that the `oxy_editor` function specifies.
- **columns** - Controls the width of the form control. The unit size is the width of the **w** character.

- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- **color** - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element that was used to insert it.
- **visible** - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- **fontInherit** - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- **fileFilter** - string value that holds comma-separated file extensions. The URL chooser uses these extensions to filter the displayed files. A value such as `"jpg,png,gif"` is mapped to a single filter that will display all `jpg`, `png`, and `gif` files.
- **hoverPseudoclassName** - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_urlChooser(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: *oxy_urlChooser* Form Control

```
urlChooser[file]:before {
    content: "A URL chooser editor that allows browsing for a URL.
          The selected URL is made relative to the currently edited file:"
       oxy_urlChooser(
       edit, "@file",
       columns 25);
}
```

Tip:
To insert a sample of the `oxy_urlChooser` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_urlChooser` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]*`/samples/form-controls`.

Video Player Form Control

The `oxy_video` built-in form control is used for providing a mechanism to play videos.

The `oxy_video` form control supports the following properties:

- **href** - The absolute or relative location of a resource. This property is mandatory. Relative values are resolved relative to the CSS. If you have media resources relative to the XML document, you can specify their paths like this:

  ```
  oxy_video(href, oxy_url(oxy_base-uri(), 'ex.mp4')), width, 400px, height, 300px)
  ```

- **width** - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units.
- **height** - Specifies the height of the form control area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units.

Example: *oxy_video* Form Control

```
object {
    content:
        oxy_video(
            href, 'resources/video.mp4',
            width, 400px,
            height, 300px),
}
```

Tip:
To insert a sample of the `oxy_video` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant (on page 3418)* by pressing **Ctrl + Space** and select the `oxy_video` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: *[OXYGEN_INSTALL_DIR]*`/samples/form-controls`.

Implementing Custom Form Controls

If the built-in form controls are not sufficient for your needs, you can implement custom form controls in Java.

Custom Form Controls Implementation

You can specify custom form controls using the following properties:

- **rendererClassName** - The name of the class that draws the edited value. It must be an implementation of *ro.sync.ecss.extensions.api.editor.InplaceRenderer*. The renderer has to be a **SWING** implementation and can be used both in the standalone and Eclipse distributions.
- **swingEditorClassName** - You can use this property for the standalone (**Swing**-based) distribution to specify the name of the class used for editing. It is a **Swing** implementation of *ro.sync.ecss.extensions.api.editor.InplaceEditor*.
- **swtEditorClassName** - You can use this property for the Eclipse plugin distribution to specify the name of the class used for editing. It is a **SWT** implementation of the *ro.sync.ecss.extensions.api.editor.InplaceEditor*.

  Note:
  If the custom form control is intended to work in the Oxygen XML Editor standalone distribution, the declaration of **swtEditorClassName** is not required. The **renderer** (the class that draws the value) has different properties from the **editor** (the class that edits the value) because you can present a value in one way and edit it in another.

- **classpath** - You can use this property to specify the location of the classes used for a custom form control. The value of the **classpath** property is an enumeration of URLs separated by comma.
- **edit** - If your form control edits the value of an attribute or the text value of an element, you can use the `@attribute_name` and `#text` predefined values and Oxygen XML Editor will perform the commit logic by itself. You can use the `custom` value to perform the commit logic yourself.

- **saHeavyFormControlClassName** - This type of form control is effectively present at all times at its allocated bounds. This is useful if you need a form control that renders dynamic or interactive SVG documents (for example, if you have an SVG document that displays tooltips when hovering over certain areas). It is also helpful if you want to use JavaFX, since JavaFX-based form controls are not compatible with the classic form control architecture.

The value of this property is a class name that must implement the *ro.sync.ecss.extensions.api.editor.InplaceHeavyEditor* method. The *JAR (on page 3420)* that contains this implementation can either be added in the **Classpath** tab in the **Document Type Configuration** dialog box *(on page 152)* for your particular *framework (on page 3420)* or specified with the `classpath` property *(on page 2523)*.

Example: Java Code

The following is a sample Java code for implementing a custom combo box form control that inserts an XML element in the content when the editing stops:

```
public class ComboBoxEditor  extends AbstractInplaceEditor {
  /**
   * @see ro.sync.ecss.extensions.api.editor.InplaceEditor#stopEditing()
   */
  @Override
   public void stopEditing() {
     Runnable customCommit =  new Runnable() {
      @Override
       public void run() {
        AuthorDocumentController documentController =
            context.getAuthorAccess().getDocumentController();
        documentController.insertXMLFragment( "<custom/>", offset);
       }
    };
    EditingEvent event =  new EditingEvent(customCommit,  true);
    fireEditingStopped(event);
  }
```

The custom form controls can use any of the predefined properties of the built-in form controls *(on page 2491)*, as well as specified custom properties.

Example: CSS

The following is an example of how to specify a custom form control in the CSS:

```
myElement {
    content: oxy_editor(
        rendererClassName, "com.custom.editors.CustomRenderer",
        swingEditorClassName, "com.custom.editors.SwingCustomEditor",
        swtEditorClassName, "com.custom.editors.SwtCustomEditor",
        edit, "@my_attr",
        customProperty1, "customValue1",
        customProperty2, "customValue2"
```

```
    )
}
```

How to Implement Custom Form Controls

To implement a custom form control, follow these steps:

1. Download the Oxygen XML Editor SDK at: https://www.oxygenxml.com/oxygen_sdk.html.
2. Implement the custom form control by extending *ro.sync.ecss.extensions.api.editor.InplaceEditorRendererAdapter*. You could also use *ro.sync.ecss.extensions.api.editor.AbstractInplaceEditor*, which offers some default implementations and listeners management.
3. Pack the previous implementation in a Java *JAR (on page 3420)* library.
4. Copy the *JAR* library to the `[OXYGEN_INSTALL_DIR]/frameworks/[FRAMEWORK_DIR]` directory.
5. In Oxygen XML Editor, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, edit the appropriate *framework*, and add the *JAR* library in the **Classpath** tab.
6. Specify the custom form control in your CSS, as described above.

Tip:
To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: `[OXYGEN_INSTALL_DIR]/samples/form-controls`.

Resources

For more information about form controls, watch our video demonstration:

https://www.youtube.com/embed/-WY3wzkMSLM

Editing Processing Instructions Using a Form Control

Oxygen XML Editor allows you to edit *processing instructions*, *comments*, and *CDATA* by using CSS extensions.

Note:
You can edit both the content and the attribute value from a *processing instruction*.

Example: Editing an Attribute from a Processing Instruction

PI content:

```
<?pi_target attr="val"?>
```

CSS:

```
@namespace oxy "http://www.oxygenxml.com/extensions/author";

oxy|processing-instruction:before {
    display:inline;
    content:
        "EDIT attribute: " oxy_textfield(edit, '@attr', columns, 15);
    visibility:visible;
}
oxy|processing-instruction{
    visibility:-oxy-collapse-text;
}
```

Text Field Form Control *(on page 2518)*

Collapse Text: -oxy-collapse-text Property Value *(on page 2463)*

Displaying Processing Instructions from Other XML Editors *(on page 2427)*

Custom CSS Pseudo-classes

You can set your custom CSS pseudo-classes on the nodes from the *AuthorDocument* model. These are similar to the normal XML attributes, with the important difference that they are not serialized, and by changing them, the document does not create undo and redo edits (the document is considered unmodified). You can use custom pseudo-classes for changing the style of an element (and its children) without altering the document.

In Oxygen XML Editor they are used to hide/show the `colspec` elements from CALS tables. To take a look at the implementation, see:

1. *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/css/cals_table.css` (Search for `-oxy-visible-colspecs`)
2. The definition of action `table.toggle.colspec` from the DocBook *framework (on page 3420)* makes use of the pre-defined *TogglePseudoClassOperation* **Author** mode operation.

Here are some examples:

Example: Controlling the visibility of a section using a pseudo-class

You can use a non standard (custom) pseudo-class to impose a style change on a specific element. For instance, you can have CSS styles matching the custom pseudo-class `access-control-user`, like the one below:

```
section {
  display:none;
}
```

```
section:access-control-user {
  display:block;
}
```

By setting the pseudo-class `access-control-user`, the element section will become visible by matching the second CSS selector.

Example: Coloring the elements at the current cursor location

You could create an *AuthorCaretListener* that sets the `caret-visited` pseudo-class to the element at the cursor location. The effect will be that all the elements traversed by the cursor become red.

```
*:caret-visited {
  color:red;
}
```

The API that you can use from the *CaretListener*:

ro.sync.ecss.extensions.api.AuthorDocumentController#setPseudoClass(java.lang.String, ro.sync.ecss.extensions.api.node.AuthorElement)

ro.sync.ecss.extensions.api.AuthorDocumentController#removePseudoClass(java.lang.String, ro.sync.ecss.extensions.api.node.AuthorElement)

Predefined Pseudo-Class Author Mode Operations

Pre-defined **Author** mode operations can be used directly in your *framework* to work with custom pseudo-classes:

1. *TogglePseudoClassOperation*
2. *SetPseudoClassOperation*
3. *RemovePseudoClassOperation*

Using the :before(n) and :after(n) CSS Pseudo-Elements

Although not standard, this extension may be useful if you want to style sections by adding multiple levels of static content. To add static content to an element, you would normally use a `:before` or `:after` pseudo-element.

This example adds static text before the title ("Chapter 1", "Chapter 2", etc.):

```
h1:before {
  content: "Chapter " counter(chapter) ".";
  color: blue;
}
```

All of this is styled with the same color (blue in this example). Using standard CSS, it is impossible to style specific aspects of it (for example, just the chapter number with a larger font and with red). However, you can do it using multiple `before(n)` or `after(n)` pseudo-elements:

```
h1:before(3) {
  content: "Chapter ";
  color: blue;
}
h1:before(2) {
  content: counter(chapter);
  color: red;
  font-size: large;
}
h1:before(1) {
  content: ".";
  color: blue;
}
```

Notes:

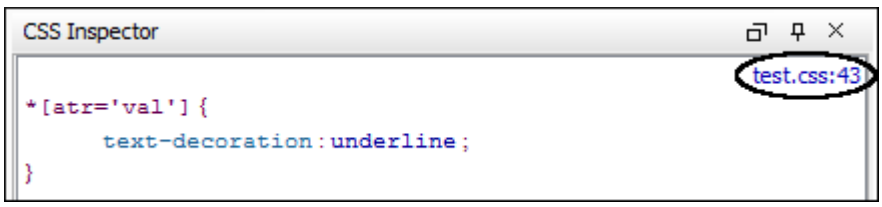
- The bigger the level, the more distant the pseudo-element is.
- Level 1 corresponds to normal `:before` or `:after` pseudo-elements.

Debugging CSS Stylesheets

To assist you with debugging and customizing CSS stylesheets the **Author** mode includes a **CSS Inspector** view *(on page 651)* to examine the CSS rules that match the currently selected element.

This tool is similar to the Inspect Element development tool that is found in most browsers. The **CSS Inspector** view allows you to see how the CSS rules are applied and the properties defined. Each rule that is displayed in this view includes a link to the line in the CSS file that defines the styles for the element that matches the rule. You can use the link to open the appropriate CSS file and edit the style rules. Once you have found the rule you want to edit, you can click the link in the top-right corner of that rule to open the CSS file in the editor.

Figure 619. CSS Inspector View



There are two ways to open the CSS Inspector view:

1. Select **CSS Inspector** from the **Window > Show View** menu.
2. Select the **Inspect Styles** action from the contextual menu in **Author** mode.

Extending Oxygen With the SDK

Oxygen XML Editor has an SDK that can be used as a base to develop *frameworks (on page 3420)* and *plugins (on page 3422)*. It can be also used to create projects that use the Oxygen XML Author Component or Oxygen XML Web Author. The SDK is a Java library available under the Oxygen XML SDK licensing terms and is delivered with a set of examples that demonstrate how to extend *Oxygen* XML functionality through API calls. The SDK is available at https://www.oxygenxml.com/oxygen_sdk.html.

Important:
From a legal standpoint, you can freely develop and share extensions using the **Oxygen SDK** ONLY if you have a legal, active license to use Oxygen XML Editor and ONLY if such extensions are used from inside Oxygen XML Editor. To use such extensions outside of Oxygen XML Editor (for example, a 3rd-party application that has Oxygen XML Editor built in to it), an additional license must be purchased to use the SDK according the **Oxygen XML SDK Licensing Policy** .

Extending Oxygen XML Editor with Plugins

A *plugin (on page 3422)* is a software component that adds extra functionality to the standalone version of the application using a series of application-provided extension points.

This chapter explains how to write and install a *plugin* for the standalone version of Oxygen XML Editor. The Plugins Development Kit contains sample *plugins* (source and compiled Java code) and the Javadoc API necessary for developing custom *plugins*.

If you want to customize the Oxygen XML Editor Eclipse plugin you can look at the Eclipse IDE Integration Sample Project to see how an Eclipse plugin can interact with the Oxygen XML Editor APIs.

General Configuration of an Oxygen XML Editor Plugin

The Oxygen XML Editor functionality can be extended with *plugins (on page 3422)* that implement a clearly specified API. On the Oxygen XML Editor website, there is an SDK with sample *plugins* (source and compiled Java code) and the Javadoc API necessary for developing custom *plugins*.

The minimal implementation of a *plugin* must provide:

- A Java class that extends the *ro.sync.exml.plugin.Plugin* class.
- A Java class that implements the *ro.sync.exml.plugin.PluginExtension* interface.
- A *plugin* descriptor file called `plugin.xml`.

A *ro.sync.exml.plugin.PluginDescriptor* object is passed to the constructor of the subclass of the *ro.sync.exml.plugin.Plugin* class. It contains the following data items about the *plugin*:

- **basedir** (*File* object) - The base directory of the *plugin*.
- **description** (*String* object) - The description of the *plugin*.
- **name** (*String* object) - The name of the *plugin*.
- **vendor** (*String* object) - The vendor name of the *plugin*.
- **version** (*String* object) - The *plugin* version. The allowed format is: `MAJOR.MINOR.PATCH` (for example, `1.0.2`).
- **id** (*String* object) - A unique identifier.
- **classLoaderType** - You can choose between `preferOxygenResources` (default value) and `preferReferencedResources`. When choosing `preferOxygenResources`, the libraries that are referenced in the Oxygen XML Editor `lib` directory will have precedence over those referenced in the `plugin.xml` configuration file, if they have the same package names. When choosing `preferReferencedResources`, the libraries that are referenced in the `plugin.xml` configuration file will have precedence over those found in the Oxygen XML Editor `lib` directory, if they have the same package names.

The *plugin* descriptor is an XML file that defines how the *plugin* is integrated in Oxygen XML Editor and what libraries are loaded. The structure of the *plugin* descriptor file is fully described in a DTD grammar located in *[OXYGEN_INSTALL_DIR]*`/plugins/plugin.dtd`. Here is a sample *plugin* descriptor used by the *Capitalize Lines* sample *plugin*:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin
    name="Capitalize Lines"
    description="Capitalize the first character on each line"
    version="1.0.0"
    vendor="SyncRO"
    class="ro.sync.sample.plugin.caplines.CapLinesPlugin">
    <runtime>
        <library name="lib/caplines.jar"/>
    </runtime>
    <extension type="selectionProcessor"
    class="ro.sync.sample.plugin.caplines.CapLinesPluginExtension"
           keyboardShortcut="ctrl shift EQUALS"/>
</plugin>
```

If your *plugin* is of the **Selection**, **Document** or **General** types, and thus contributes an action either to the contextual menu or to the main menu of the **Text** editing mode, then you can assign a keyboard shortcut for it. You can use the `@keyboardShortcut` attribute for each `<extension>` element to specify the desired shortcut.

Tip:
To compose string representations of the desired shortcut keys you can go to **Options > Menu Shortcut Keys**, select an action, and click **Edit**. Then choose the desired key sequence and use the representation that appears in the resulting dialog box.

Referencing Libraries

To reference libraries, use either of the following elements:

- `<library name="path/libraryName">` - To point to specific libraries. Notice that the value of `library name` includes the path (relative or absolute) to the library.

  Note:
  You can use the *${oxygenInstallDir}* editor variable *(on page 340)* as part of the value of the `@name` attribute. You can also use a system variable (`${system(var.name)}`) or environment variable (`${env(VAR_NAME)}`).

- `<librariesFolder name="path/libraryFolderPath">` - To point to multiple libraries located in the specified folder. Notice that the value of `libraryFolder name` includes the path (relative or absolute) to the library folder.

Both elements support the `@scope` attribute that defines the loading priority. It can have one of the following two values:

- **local** - The library is loaded in the *plugin's* own class loader. This is the default behavior.
- **global** - The library is loaded in the main application class loader as the last library in the list (as if it would be present in the application `lib` directory).

Dependency Injection for Plugins

If you want to share a single instance of a certain class between plugin extensions and custom operations (to prevent instances from being repeated), you can declare a `<context>` element in your `plugin.xml` file:

```
<context class="my.package.ContextClass"/>
```

Important:
The `my.package.ContextClass` class should have a no-arguments constructor that will be called when the class is instantiated.

This will result in an instance being automatically generated. You can access this instance in an extension class by defining a field of that type and annotated with the `ro.sync.exml.plugin.PluginContext` annotation:

```
@PluginContext
ContextClass contextInstance;
```

The defined field is automatically populated with the single instance.

Tip:
By default, an instance of the `PluginDescriptor` class is also injectable.

Installing an Oxygen XML Editor Plugin

Choose one of the following methods to install a *plugin (on page 3422)* in Oxygen XML Editor:

Manual Method

To manually install a *plugin* in Oxygen XML Editor, follow these steps:

1. Go to the Oxygen XML Editor installation directory and locate the `plugins` directory.

   Note:
   The `plugins` directory contains all the *plugins* available to Oxygen XML Editor.

2. In the `plugins` directory, create a subfolder to store the *plugin* files (for example, *`[OXYGEN_INSTALL_DIR]`*`/plugins/myPlugin`).
3. In the new folder, place the *plugin* descriptor file (`plugin.xml`), the Java classes of the *plugin*, and the other files that are referenced in the descriptor file.
4. Restart Oxygen XML Editor.

Automatic Method

To install an add-on that is hosted on a remote update site, follow these steps:

1. Go to **Help > Install new add-ons**.
2. In the displayed dialog box, enter or paste the update site that hosts the add-on in the **Show add-ons from** field (or select it from the drop-down menu, if applicable). The default add-ons are hosted on **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml**. If you want to see a list of all the default and sample add-ons that are available on the *Oxygen* remote update sites, choose **ALL AVAILABLE SITES** from the drop-down menu. The add-ons list contains the name, status, update version, Oxygen XML Editor version, and the type of the add-on (either **framework**, or **plugin**). A short description of each add-on is presented under the add-ons list.

   Note:
   To see all the versions of the add-ons, deselect **Show only compatible add-ons** and **Show only the latest version of the add-ons**. Incompatible add-ons are shown only to acknowledge their presence on the remote update site, but you cannot install an incompatible add-on.

3. Choose the add-ons you want to install, click the **Next** button, then follow the on-screen instructions.

Note:
Accepting the license agreement of the add-on is a mandatory step in the installation process.

Note:
All add-ons are installed in the `extensions` directory inside the Oxygen XML Editor preferences directory *(on page 132)*.

Tip:
As an alternate approach, you can add an **Install** button to a web page that links to a URL that has the syntax `https://host/path/to/updateSite.xml?oxygenAddonId=addOnIDValue` and drop the button into the application's main editing area.

Types of Plugin Extensions Available with the SDK

A *plugin (on page 3422)* can have one or more defined *plugin extensions* that provide functionality to the application. This section presents the *plugin extensions* that are available.

Workspace Access Plugin Extension

This type of *plugin (on page 3422)* allows you to contribute actions to the main menu and toolbars, create custom views, interact with the application workspace, make modifications to opened documents, and add listeners for various events.

Many complex integrations (such as integrations with Content Management Systems) usually requires access to some workspace resources such as toolbars, menus, views, and editors. This type of *plugin* is also useful because it allows you to make modifications to the XML content of an open editor.

The *plugin* must implement the *ro.sync.exml.plugin.workspace.WorkspaceAccessPluginExtension* interface. The callback method *applicationStarted* of this interface allows access to a parameter of the *ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace* type (allows for API access to the application workspace).

The *StandalonePluginWorkspace* interface has three methods that can be called to customize toolbars, menus, and views:

addToolbarComponentsCustomizer

Contributes to or modifies existing toolbars. You can specify additional toolbar IDs in the associated `plugin.xml` descriptor file using the following construct:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin name="CustomWorkspaceAccess" ..............>
 <runtime>
```

```
  ........
 </runtime>

 <extension type="WorkspaceAccess" ...............>
 ...............
  <toolbar id="SampleID" initialSide="NORTH" initialRow="1"/>
</plugin>
```

The `<toolbar>` element adds a toolbar in the Oxygen XML Editor interface and allows you to contribute your own *plugin*-specific actions. The following attributes are supported:

- **id** - Unique identifier for the toolbar.
- **initialSide** - Specifies the place where the toolbar is initially displayed. The allowed values are `NORTH` and `SOUTH`.
- **initialRow** - Specifies the initial row on the specified side where the toolbar is displayed. For example, the first toolbar has an initial row of `0` and the next toolbar has an initial row of `1`.

The *ro.sync.exml.workspace.api.standalone.ToolbarInfo* toolbar component information with the specified ID will be provided to you by the customizer interface. Therefore, you will be able to provide Swing components that will appear on the toolbar when the application starts.

addViewComponentCustomizer

Contributes to or modifies existing views, or contributes to the reserved custom view. You can specify additional view IDs in the associated `plugin.xml` descriptor using the following construct:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin name="CustomWorkspaceAccess" ..............>
 <runtime>
  ........
 </runtime>

 <extension type="WorkspaceAccess" ...............>
 ...............
 <view id="SampleID" initialSide="WEST" initialRow="0"/>
</plugin>
```

The `<view>` element adds a view in the Oxygen XML Editor interface and allows you to contribute your own *plugin*-specific UI components. The following attributes are supported:

- **id** - Unique identifier of the view component.
- **initialSide** - Specifies the place where the view is initially displayed. The allowed values are: `NORTH`, `SOUTH`, `EAST`, and `WEST`.
- **initialRow** - Specifies the initial row on the specified side where the view is displayed. For example, in Oxygen XML Editor, the **Project** view *(on page 413)* has an initial row of `0` and the **Outline** view *(on page 549)* has an initial row of `1`. Both views are in the WEST part of the workbench.
- **initialState** - Specifies the initial state of the view. The allows values are: `hidden`, `docked`, `autohide`, and `floating`. By default, the view is visible and docked.

The `<view>` element also supports an optional `<perspective>` child element so that you can show or hide a certain view for a specified perspective. The `<perspective>` element supports the following attributes:

- **id** (required) - Unique identifier for the perspective. The possible values are: `editor`, `dita`, `xslt_debugger`, `xquery_debugger`, and `database`.
- **initState** (optional) - Specifies the initial state of the perspective. The allows values are: `hidden`, `docked`, `autohide`, and `floating`. By default, the view is visible and docked.

The *ro.sync.exml.workspace.api.standalone.ViewInfo* view component information with the specified ID will be provided to you by the customizer interface. Therefore, you will be able to provide Swing components that will appear on the view when the application starts.

addMenuBarCustomizer

Contributes to or modifies existing menu components.

Access to the open editors can be done by first getting access to all URLs opened in the workspace using the *StandalonePluginWorkspace.getAllEditorLocations(int editingArea)* API method. There are two available editing areas: the **DITA Maps Manager** editing area and the main editing area. Using the URL of an open resource, you can gain access to it using the *StandalonePluginWorkspace.getEditorAccess(URL location, int editingArea)* API method. A *ro.sync.exml.workspace.api.editor.WSEditor* then allows access to the current editing page.

A special editing API is supported for the **Text** mode (*ro.sync.exml.workspace.api.editor.page.text.WSTextEditorPage*) and the **Author** mode (*ro.sync.exml.workspace.api.editor.page.author.WSAuthorEditorPage*).

To be notified when editors are opened, selected, and closed, you can use the *StandalonePluginWorkspace.addEditorChangeListener* API method to add a listener.

Examples:

- A simple Maven-based sample of a workspace access plugin is available here: https://github.com/oxygenxml/sample-plugin-workspace-access.
- A more complex sample of a workspace access plugin mimicking a CMS integration is available in the Author SDK: https://www.oxygenxml.com/oxygen_sdk.html.

Example: Adding a Custom View in Oxygen XML Editor

To add a custom view in Oxygen XML Editor, follow this procedure:

1. Locate the `plugin.xml` descriptor file for your plugin (should be located inside the **plugins** folder, for example, *`[OXYGEN_INSTALL_DIR]/plugins/myPlugin`*). Define the ID of the view you want to add and specify the location where it will be placed:

   ```
   <view id="SampleWorkspaceAccessID" initialSide="WEST" initialRow="0"/>
   ```

2. In your Workspace Access Plugin Extension *(on page 2534)* implementation, where the `applicationStarted` callback is received, add a view component customizer like this:

   ```
   pluginWorkspaceAccess.addViewComponentCustomizer(new ViewComponentCustomizer() {
    public void customizeView(ViewInfo viewInfo) {
      if(
        //The view ID defined in the "plugin.xml"
        "SampleWorkspaceAccessID".equals(viewInfo.getViewID())) {
        cmsMessagesArea = new JTextArea("CMS Session History:");
        viewInfo.setComponent(new JScrollPane(cmsMessagesArea));
        viewInfo.setTitle("CMS Messages");
        viewInfo.setIcon(Icons.getIcon(Icons.CMS_MESSAGES_CUSTOM_VIEW_STRING));
      }
    }
   });
   ```

3. Define the `cmsMessagesArea` as a *static* field (if you can access the messages area from anywhere in your code).

Related Information:
https://www.oxygenxml.com/oxygen_sdk/oxygen_standalone_plugins.html

Workspace Access Plugin Extension (JavaScript-Based)

This is a JavaScript-based *plugin (on page 3422)* extension that allows you to contribute actions to the main menu and toolbars, create custom views, interact with the application workspace, make modifications to opened documents, and add listeners for various events.

This extension can use the same API as the Workspace Access plugin extension *(on page 2534)*, but the implementation is JavaScript-based and uses the bundled Rhino library to create and work with Java API from the JavaScript code.

First, you need to create a custom plugin folder inside the **plugins** folder (for example, *[OXYGEN_INSTALL_DIR]*`/plugins/myPlugin`). This folder will contain your custom *plugin* descriptor file (`plugin.xml`) and all other resources for the plugin.

The *plugin* descriptor file (named `plugin.xml`) needs to reference a JavaScript file, as in the following example:

```
<!DOCTYPE plugin PUBLIC "-//Oxygen Plugin" "../plugin.dtd">
<plugin
 id="unique.id.value"
 name="Add Action To DITA Maps Manager popup-menu"
 description="Plugin adds action to DITA Maps Manager contextual menu."
 version="1.0"
 vendor="Syncro Soft"
 class="ro.sync.exml.plugin.Plugin"
 classLoaderType="preferReferencedResources">
 <extension type="WorkspaceAccessJS" href="wsAccess.js"/>
</plugin>
```

In the example above, the JavaScript file `wsAccess.js` (located in your custom plugin folder *(on page 2538)*) will be called. This JavaScript file needs to have two JavaScript methods defined inside. Methods that will be called when the application starts and when it ends:

```
function applicationStarted(pluginWorkspaceAccess) {
.........
}

function applicationClosing(pluginWorkspaceAccess) {
.........
}
```

With regard to the `applicationStarted` callback, besides using the *ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace* API with the `pluginWorkspaceAccess` parameter, you can also use a globally defined field called `jsDirURL` that points to the folder where the JavaScript file is located.

Below is a much larger example with a JavaScript Workspace Access *plugin* extension implementation that adds a new action in the contextual menu of the **DITA Maps Manager** view *(on page 3073)*. The action starts the `notepad.exe` application and passes the reference to the currently selected `<topicref>` to it.

```
function applicationStarted(pluginWorkspaceAccess) {
 Packages.java.lang.System.err.println("Application started "
      + pluginWorkspaceAccess);
 edChangedListener = {
  /*Called when a DITA Map is opened*/
   editorOpened: function (editorLocation) {
```

```
 Packages.java.lang.System.err.println("\nrunning " + editorLocation);
/*Get the opened DITA Map*/
 editor = pluginWorkspaceAccess.getEditorAccess(editorLocation,
 Packages.ro.sync.exml.workspace.api.PluginWorkspace.DITA_MAPS_EDITING_AREA);
 ditaMapPage = editor.getCurrentPage();
/*Add listener called when right-click is done in the DITA Maps manager*/
 customizerObj = {
 customizePopUpMenu: function (popUp, ditaMapDocumentController) {
 Packages.java.lang.System.err.println("RIGHT CLICK" + popUp);
 tree = ditaMapPage.getDITAMapTreeComponent();
/*Selected tree path*/
 sel = tree.getSelectionPath();
 if (sel != null) {
 selectedElement = sel.getLastPathComponent();
/*Reference attribute*/
 href = selectedElement.getAttribute("href");
 if (href != null) {
   try {
/*Create absolute reference*/
 absoluteRef = new Packages.java.net.URL(selectedElement.getXMLBaseURL(),
        href.getValue());
 Packages.java.lang.System.err.println("Computed absolute reference "
      + absoluteRef);
 mi = new Packages.javax.swing.JMenuItem("Run notepad");
     popUp.add(mi);
     actionPerfObj = {
     actionPerformed: function (e) {
       try {
        Packages.java.lang.Runtime.getRuntime().exec("notepad.exe "
            + pluginWorkspaceAccess.getUtilAccess().locateFile(absoluteRef));
       }
     catch (e1) {
      e1.printStackTrace();
       }
      }
     }
 mi.addActionListener(new JavaAdapter(Packages.java.awt.event.ActionListener,
         actionPerfObj));
    }
    catch (e1) {
     Packages.java.lang.System.err.println(e1);
    }
```

```
      }
     }
    }
   }

   ditaMapPage.setPopUpMenuCustomizer(new Packages.ro.sync.exml.workspace.api.
editor.page.ditamap.DITAMapPopupMenuCustomizer(customizerObj));
  }
 }
   edChangedListener = new JavaAdapter(Packages.ro.sync.exml.workspace.api.
listeners.WSEditorChangeListener, edChangedListener);
   pluginWorkspaceAccess.addEditorChangeListener(
   edChangedListener,
   Packages.ro.sync.exml.workspace.api.PluginWorkspace.DITA_MAPS_EDITING_AREA);
}

 function applicationClosing(pluginWorkspaceAccess) {
   Packages.java.lang.System.err.println("Application closing "
        + pluginWorkspaceAccess);
}
```

Declaring Multiple Modules

JavaScript-based plugins can include multiple modules of JavaScript files in the plugin. In those files, you can declare functions that can be used in the main *WorkspaceAccessJS* JavaScript file. Thus, you can use those external script files as a library of functions. The modules must be declared in the plugin descriptor file (`plugin.xml`).

For example:

```
<!DOCTYPE plugin PUBLIC "-//Oxygen Plugin" "../plugin.dtd">
<plugin
 id="unique.id.value"
 name="Add Action To DITA Maps Manager popup-menu"
 description="Plugin adds action to DITA Maps Manager contextual menu."
 version="1.0"
 vendor="Syncro Soft"
 class="ro.sync.exml.plugin.Plugin"
 classLoaderType="preferReferencedResources">
 <extension type="WorkspaceAccessJS" href="wsAccess.js"/>
 <extension type="WorkspaceAccessJSModule" href="wsAccessModule1.js"/>
 <extension type="WorkspaceAccessJSModule" href="wsAccessModule2.js"/>
</plugin>
```

For more information and some samples, see GitHub Project with Multiple Workspace Access JavaScript-Based Plugin Samples.

Trusted Hosts Plugin Extension

This type of *plugin (on page 3422)* can be used by developers to automatically allow or reject remote connections that Oxygen XML Editor would normally ask the user for confirmation.

The name of the *plugin* extension is ***TrustedHosts***. For security reasons, Oxygen XML Editor intercepts all connections to remote hosts and displays a dialog box that asks the user for confirmation. By implementing this plugin extension, the application will automatically allow or deny connections from websites you consider and configure as trusted or untrusted.

To develop an integration project, follow this steps:

- Copy the `oxygen.jar` file from *`[OXYGEN_INSTALL_DIR]/lib`* to the `lib` folder of your project.
- Implement the *ro.sync.exml.plugin.workspace.security.TrustedHostsProviderExtension* extension point.
- In the *plugin* descriptor file, define the `<extension>` element that points to the implementation of your classes:

```
<extension type="TrustedHosts" class="my.trusted.hosts.provider.class.qualified.name"/>
```

Detailed information regarding the accepted or rejected connections from plugins are logged in the **Information view** *(on page 522)*.

Example implementation:

```
import ro.sync.exml.plugin.workspace.security.Response;
import ro.sync.exml.plugin.workspace.security.TrustedHostsProviderExtension;

public class DummyTrustedHostsProviderImpl implements
            TrustedHostsProviderExtension {
  @Override
  public Response isTrusted(String hostName) {
    // Connections from this website will always be
    // considered safe and always accepted.
    if ("trusted.website:80".equals(hostName)) {
      return TRUSTED;
    } else if("malicious.website:80".equals(hostName)) {
      // Always reject connections from malicious website
      return UNTRUSTED;
    }
    // All other connections are unknown, so a dialog will
    // appear and ask user's confirmation
    // to allow or deny the connection to this website.
```

```
            return UNKNOWN;
        }
}
```

Author Stylesheet Plugin Extension

This type of *plugin (on page 3422)* allows you to add a stylesheet (CSS or LESS) that renders elements in **Author** mode.

To specify additional stylesheets, edit the *plugin* descriptor and add `<extension>` elements that point to them, as in the following example:

```
<extension type="AuthorStylesheet" href="showTables.css"/>
<extension type="AuthorStylesheet" href="hideButtons.css"/>
```

Using this mechanism, you can add one or more CSS stylesheets to merge with the existing ones. Whenever you add a new stylesheet using this *plugin*, it will have priority over all other stylesheets applied on the file edited in **Author** mode.

If your implementation requires more flexibility (such as a dynamic change of the stylesheet), you should consider using the *StylesFilter* plugin extension *(on page 2550)*.

Additional Framework Plugin Extension

This type of *plugin (on page 3422)* allows you to add a new framework straight from the *plugin*.

To specify additional frameworks, edit the *plugin* descriptor and add `<extension>` elements that point to them, as in the following example:

```
<extension type="AdditionalFrameworks" path="framework_directory"/>
```

The path attribute should be a sub-directory of the plugin. If the *plugin* is installed as an add-on *(on page 126)*, the new framework will be set as read-only and editing it will only be possible if you *duplicate* it *(on page 146)*. If the *plugin* is installed in the *`[OXYGEN_INSTALL_DIR]`*`/plugins` directory, the new frameworks will be editable.

Additional XProc Engine Plugin Extension

This type of *plugin (on page 3422)* contributes a folder that contains an external XProc engine.

The name of the *plugin* extension is ***AdditionalXprocEngine*** and it makes it easier to integrate an external XProc engine *(on page 1587)*. After the plugin is installed, when you run an XProc transformation scenario, your external XProc engine can be selected from the **Processor** drop-down menu in the **XProc** tab.

An example of the `plugin.xml` file looks like this:

```
<plugin
 id="morgana.xproc.addon"
 name="Contribute Morgana XProc"
```

```
 description="Contribute Morgana XProc"
 version="1.0"
 vendor="Syncro Soft"
 class="ro.sync.exml.plugin.Plugin"
 classLoaderType="preferReferencedResources">
 <extension type="AdditionalXProcEngine" path="MorganaXProcEngine/"></extension>
</plugin>
```

The `@path` attribute points to the XProc engine folder that contains the `engine.xml` and all the libraries necessary to run it.

Components Validation Plugin Extension

This type of *plugin (on page 3422)* allows you to customize the menus, toolbars, and other components by enabling or filtering them from the user interface.

This *plugin* provides the following API:

***ComponentsValidatorPluginExtension* interface**

There is one method that must be implemented:

getComponentsValidator()

Returns a *ro.sync.exml.ComponentsValidator* implementation class used for validating the menus, toolbars, and their actions.

***ComponentsValidator* interface**

Provides methods to filter various features from being added to the GUI of Oxygen XML Editor:

validateMenuOrTaggedAction(String[] menuOrActionPath)

Checks if a menu or a tag action from a menu is allowed and returns a `boolean` value. A tag is used to uniquely identifying an action. The *String[]* argument is the tag of the menu / action and the tags of its parent menus if any.

validateToolbarTaggedAction(String[] toolbarOrAction)

Checks if an action from a toolbar is allowed and returns a *boolean* value. The *String[]* argument is the tag of the action from a toolbar and the tag of its parent toolbar if any.

validateComponent(String key)

Checks if the given component is allowed and returns a `boolean` value. The *String* argument is the tag identifying the component. You can remove toolbars entirely using this callback.

validateAccelAction(String category, String tag)

Checks if the given accelerator action is allowed to appear in the GUI and returns a `boolean` value. An accelerator action can be uniquely identified so it will be removed both from toolbars or menus. The first argument represents the action category, the second is the tag of the action.

validateContentType(String contentType)

Checks if the given content type is allowed and returns a `boolean` value. The *String* argument represents the content type. You can instruct Oxygen XML Editor to ignore content types such as `text / xsl` or `text / xquery`.

validateOptionPane(String optionPaneKey)

Checks if the given options page can be added in the preferences option tree and returns a `boolean` value. The *String* argument is the option pane key.

validateOption(String optionKey)

Checks if the given option can be added in the option page and returns a `boolean` value. The *String* argument is the option key. This method is mostly used for internal use and it is not called for each option in a preferences page.

validateLibrary(String library)

Checks if the given library is allowed to appear listed in the **About** dialog box and returns a `boolean` value. The *String* argument is the library. This method is mostly for internal use.

validateNewEditorTemplate(EditorTemplate editorTemplate)

Checks if the given template for a new editor is allowed and returns a `boolean` value. The *EditorTemplate* argument is the editor template. An *EditorTemplate* is used to create an editor for a given extension. You can thus filter what appears in the list of the **New** dialog box.

isDebuggerperspectiveAllowed()

Checks if the debugger *perspective (on page 3422)* is allowed and returns a `boolean` value.

validateSHMarker(String marker)

Checks if the given marker is allowed and returns a `boolean` value. The *String* argument represents the syntax highlight marker to be checked. If you decide to filter certain content types, you can also filter the syntax highlight options so that the content type is no longer present in the Preferences options tree.

validateToolbarComposite(String toolbarCompositeTag)

Checks if the toolbar composite is available. A toolbar composite is a toolbar component such as a drop-down menu.

Tip:
The best way to decide what to filter is to observe the values that Oxygen XML Editor passes when these callbacks are called. You have to create an implementation for this interface that lists in the console all values received by each function. Then you can decide on the values to filter and act accordingly.

Contribute Additional Languages Plugin Extension

This type of *plugin (on page 3422)* allows you to contribute new translation languages to the Oxygen XML Editor UI.

The ***AdditionalUITranslation*** *plugin* extension provides the ability to contribute new translation languages to the interface in Oxygen XML Editor.

A sample `plugin.xml` file looks like this:

```
<plugin
 id="romanian.i18n.provider"
 name="Add Romanian as an user interface language"
 description="Add Romanian as an user interface language"
 version="1.0"
 vendor="Syncro Soft"
 class="ro.sync.exml.plugin.Plugin">
 <extension type="AdditionalUITranslation" href="translation.xml"/>
</plugin>
```

where the `translation.xml` has a structure like this:

```
<translation>
    <languageList>
        <language description="Romanian" lang="ro_RO" localeDescription="Romana"/>
    </languageList>
    <key value="Error">
        <val lang="ro_RO">Eroare</val>
    </key>
.........................
</translation>
```

If all error keys are not translated in the custom `translation.xml` contributed by the plugin, the fallback is the default English translation. Once this plugin is installed, the **Languages** drop-down menu in the **Options > Preferences > Global** *(on page 133)* will be updated to include the newly added languages. The end-user will still need to select that language in the drop-down menu to use it.

Contribute External DITA-OT Distribution Plugin Extension

This type of *plugin (on page 3422)* allows you to contribute an external DITA-OT distribution to Oxygen XML Editor.

Oxygen XML Editor comes bundled with DITA-OT version 4.1.2. If you want to use a different DITA-OT version, the `AdditionalDITAOT` *plugin* extension provides the ability to contribute an external distribution of the *DITA Open Toolkit* to Oxygen XML Editor.

Example

For instance, if you wanted to use a DITA-OT version 1.8, your `plugin.xml` file might look like this:

```
<plugin
 id="dita-ot-18"
 name="Contribute DITA-OT 1.8"
 description="Contributes DITA-OT 1.8"
 version="1.0"
 vendor="Syncro Soft"
 class="ro.sync.exml.plugin.Plugin">
 <extension type="AdditionalDITAOT" path="DITA-OT1.8.5" description="DITA-OT 1.8"/>
</plugin>
```

The `@path` attribute points to a folder located relative to the `plugin.xml` file and this folder is where the additional distribution of DITA-OT would be located.

When Oxygen XML Editor is started with this plugin enabled, that addition DITA-OT version can now be selected in the **DITA Open Toolkit** option in the **DITA** preferences page *(on page 277)*.

Custom Protocol Plugin Extension

This type of *plugin (on page 3422)* allows you to work with a custom designed protocol for retrieving and storing files.

It provides the following API:

***URLStreamHandlerPluginExtension* interface**

There is one method that must be implemented:

getURLStreamHandler(String protocol)

It takes as an argument the name of the protocol and returns a `URLStreamHandler` object, or null if there is no URL handler for the specified protocol.

This type of *plugin* extension can be usually combined with a Workspace Access plugin extension *(on page 2534)* that can add a custom toolbar with custom actions for opening documents from a certain source.

As an alternative, two older *plugin* extensions can also be used to add a toolbar action for showing a custom URL chooser:

***URLChooserPluginExtension2* interface**

Makes it possible to create your own dialog box that works with the custom protocol. This interface provides two methods:

chooseURLs(StandalonePluginWorkspace workspaceAccess)

Returns a `URL[]` object that contains the URLs the user decided to open with the custom protocol. You can invoke your own URL chooser dialog box here and then return the chosen URLs having your own custom protocol. You have access to the workspace of Oxygen XML Editor.

getMenuName()

Returns a `String` object that is the name of the entry added in the **File** menu.

***URLChooserToolbarExtension* interface**

Makes it possible to provide a toolbar entry that is used for launching the custom URLs chooser from the *URLChooserPluginExtension* implementation. This interface provides two methods:

getToolbarIcon()

Returns the `javax.swing.Icon` image used on the toolbar.

getToolbarTooltip()

Returns a `String` that is the tooltip used on the toolbar button.

Lock Handler Plugin Extension

This type of *plugin extension (on page 3422)* is used for locking resources from a specific protocol.

It provides the following API:

***LockHandlerFactoryPluginExtension* interface**

You need to implement the following two methods:

LockHandler getLockHandler()

Gets the lock handler for the current handled protocol. Might be `null` if not supported.

boolean isLockingSupported(String protocol)

Checks if a lock handler can be provided for a specific protocol.

To use this type of extension in your *plugin*, create an extension of *LockHandlerFactory* type in your `plugin.xml` file and specify the class implementing *LockHandlerFactoryPluginExtension*:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
```

```
<plugin name="CustomLockHandler" ..............>
 <runtime>
  ........
 </runtime>

 <extension type="LockHandlerFactory"
         class="LockHandlerFactoryPluginExtensionImpl"/>
 ...............

</plugin>
```

Open Redirect Plugin Extension

This type of *plugin (on page 3422)* is useful for opening multiple files with only one open action.

For example, when a zip archive or an ODF file or an OOXML file is open in the **Archive Browser** view *(on page 2126)* a *plugin* of this type can decide to open a file also from the archive in an XML editor panel. This file can be the `document.xml` main file from an OOXML file archive or a specific XML file from a zip archive.

The *plugin* must implement the interface *OpenRedirectExtension*. It only has one callback: `redirect(URL)` that receives the URL of the file opened by the Oxygen XML Editor user. If the *plugin* decides to open also other files it must return an array of information objects (*OpenRedirectInformation[]*) that correspond to these files. Such an information object must contain the URL that is opened in a new editor panel and the content type (for example, `text/xml`). The content type is used for determining the type of editor panel. A `null` content type allows auto-detection of the file type.

Option Page Plugin Extension

This type of *plugin extension (on page 3422)* allows you to add custom **Preferences** pages.

The extension must implement the *ro.sync.exml.plugin.option.OptionPagePluginExtension* class. The provided callbacks allows you to create a custom *Swing* component that will be added to the page and to react to various calls to persistently save the page settings using the `OptionsStorage` API.

All preferences pages that are contributed by a *plugin* are listed in the **Preferences** dialog box in the **Plugins** category. As long as the added preferences page has the same name as its *plugin*, it will be promoted to the first level of the hierarchy within the **Plugins** category.

The `plugin.xml` configuration file can specify one or more such extensions using constructs like this:

```
<extension type="OptionPage" class="my.pack.CustomOptionPagePluginExtension"/>
```

Sharing Options Through Project Files

To share options that are configured in certain plugin preferences pages, you can store them in a project file (`.xpr` file extension) that can easily be shared with others. To do this, perform these steps:

1. Override `ro.sync.exml.plugin.option.OptionPagePluginExtension.getProjectLevelOptionKeys()` and return a set of options that need to be saved inside the project.
2. Install the plugin in an Oxygen XML Editor instance *(on page 2533)*.
3. In the **Project** view *(on page 413)*, create a project or open an existing one.
4. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*.
5. Configure the options in each preferences page that you want to be included in the project file and switch the storage preference to **Project Options** *(on page 3423)* in each page.

   > **Note:**
   > Some pages do not have the **Project Options** button, since the options they host might contain sensitive data (such as passwords, for example) that is unsuitable for sharing with other users.

6. Click **OK** and close the **Preferences** dialog box.

   All explicitly set values are now saved in the project file. You can then share the project file so that your team will have the same option configuration that you stored in the project file.

   > **Note:**
   > The project file extension (`.xpr`) must be preserved when the file is distributed to others.

   > **Notice:**
   > When a project is opened for the first time, a confirmation dialog box will be displayed that asks you to confirm that the project came from a trusted source. This is meant to help prevent potential security issues.

Option Page Group Plugin Extension

This type of *plugin extension (on page 3422)* allows you to add a group of custom **Preferences** pages from a plugin.

The extension must implement the *ro.sync.exml.plugin.OptionsPageGroupPluginExtension* class. The base method `OptionsPageGroupPluginExtension.addOptionPagePluginExtension(...)` allows adding multiple implementations of the `OptionPagePluginExtension` *(on page 2548)* base class.

All preferences pages that are contributed by this extension are listed as descendents of the plugin specific preferences page in the **Preferences** dialog box in the **Plugins** category.

The `plugin.xml` configuration file can specify one or more such extensions using constructs like this:

```
<extension type="OptionPageGroup" class="my.pack.CustomOptionPageGroupPluginExtension"/>
```

Resource Locking Custom Protocol Plugin Extension

This type of *plugin (on page 3422)* allows you to work with a custom designed protocol for retrieving and storing files and it can lock a resource when opening it in Oxygen XML Editor.

This type of *plugin* extends the custom protocol *plugin* type with resource locking support and provides the following API:

***URLStreamHandlerWithLockPluginExtension* interface**

The *plugin* receives callbacks following the simple protocol for resource locking and unlocking imposed by Oxygen XML Editor.

There are two additional methods that must be implemented:

getLockHandler()

Returns a `LockHandler` implementation class with the implementation of the lock specific methods from the *plugin*.

isLockingSupported(String protocol)

Returns a `boolean` that is `true` if the *plugin* accepts to manage locking for a certain URL protocol scheme (such as `ftp`, `http`, `https`, or `customName`).

Styles Filter Plugin Extension

This type of *plugin (on page 3422)* allows you to dynamically modify the CSS styles used to render elements in the **Author** mode.

The *plugin* must extend the *ro.sync.exml.plugin.author.css.filter.GeneralStylesFilterExtension* class. This class has a callback on which you can alter the styles for an **Author** mode element.

This extension point is similar with the Styles Filter that you set at the *framework (on page 3420)* level. The only difference is that the *plugin* filters styles are used for any open XML document, regardless of the document type. The changes made by this *plugin* are prioritized over the changes made by the *framework*-level filter.

Note:
Alternatively, you can use the AuthorStylesheet plugin extension *(on page 2542)*, which does not require any additional Java development and is compatible with Oxygen XML Web Author.

Related Information:
Customizing the CSS Styles Filter *(on page 2380)*

Targeted URL Stream Handler Plugin Extension

This type of *plugin (on page 3422)* can be used when it is necessary to impose custom URL stream handlers for specific URLs.

This *plugin* extension can handle the following protocols: `http`, `https`, `ftp` or `sftp`. Oxygen XML Editor usually provides specific fixed URL stream handlers. If it is set to handle connections for a specific protocol, this extension prompts for the URL stream handler for each open connection of a URL that has that protocol.

To use this type of *plugin*, you have to implement the *ro.sync.exml.plugin.urlstreamhandler.TargetedURLStreamHandlerPluginExtension* interface that provides the following methods:

boolean canHandleProtocol(String protocol)

This method checks if the *plugin* can handle a specific protocol. If this method returns `true` for a specific protocol, the *getURLStreamHandler(URL)* method will be called for each open connection of a URL having this protocol.

URLStreamHandler getURLStreamHandler(URL url)

This method provides the URL handler for the specified URL and it is called for each open connection of a URL with a protocol that has the *canHandleProtocol(String)* method return `true`.

If this method returns `null`, the default Oxygen XML Editor *URLStreamHandler* is used.

To use this type of extension in your *plugin*, create an extension of *TargetedURLHandler* type in your `plugin.xml` file and specify the class that implements *TargetedURLStreamHandlerPluginExtension*:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin name="CustomTargetedURLStreamHandlerPlugin" ..............>
 <runtime>
  ........
 </runtime>

 <extension type="TargetedURLHandler"
          class="CustomTargetedURLStreamHandlerPluginExtension"/>
 ...............

</plugin>
```

This extension can be useful in situations when connections opened from a specific host must be handled in a particular way. For example, the Oxygen XML Editor *HTTP URLStreamHandler* may not be compatible for sending and receiving SOAP using the SUN Web Services implementation. In this case, you can override the stream handler (set by Oxygen XML Editor) to use the default SUN *URLStreamHandler*, since it is more compatible with sending and receiving SOAP requests.

```
public class CustomTargetedURLStreamHandlerPluginExtension
  implements TargetedURLStreamHandlerPluginExtension {

  @Override
  public boolean canHandleProtocol(String protocol) {
    boolean handleProtocol = false;
    if ("http".equals(protocol) || "https".equals(protocol)) {
      // This extension handles both HTTP and HTTPS protocols
```

```
      handleProtocol = true;
    }
    return handleProtocol;
  }

  @Override
  public URLStreamHandler getURLStreamHandler(URL url) {
    // This method is called only for the URLs with a protocol
    // where canHandleProtocol(String) method returns true (HTTP and HTTPS)

    URLStreamHandler handler = null;

    String host = url.getHost();
    String protocol = url.getProtocol();
    if ("some_host".equals(host)) {
      // When there are connections opened from some_host, the SUN HTTP(S)
      // handlers are used
      if ("http".equals(protocol)) {
        handler = (URLStreamHandler) Class.forName("sun.net.www.protocol.http.Handler")
.getConstructor(new Class[0]).newInstance(new Object[0]);
      } else {
        handler = (URLStreamHandler) Class.forName("sun.net.www.protocol.https.Handler")
.getConstructor(new Class[0]).newInstance(new Object[0]);
      }
    }
    return handler;
  }
}
```

XML Refactoring Operations Plugin Extension

This type of *plugin (on page 3422)* allows you to specify one or more directories where the XML Refactoring operation resources are loaded.

The `RefactoringOperationsProvider` extension can be used to specify the location where custom XML Refactoring operation resources (XQuery Update script or XSLT stylesheet and Operation Descriptor files) are stored. Oxygen XML Editor will scan the specified locations to load the custom operations when the XML Refactoring tool is opened, and allows you to share your custom refactoring operations.

Example: XML Refactoring Operations Plugin Extension

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin PUBLIC "-//Oxygen Plugin" "../plugin.dtd">

<plugin
```

```
 id="refactoring.operations"
 name="Refactoring operations plugin"
 description="Contains operation descriptors and related scripts"
 version="1.0">
 <extension type="RefactoringOperationsProvider">
  <folder path="customDir/"/>
  <folder path="customDir2"/>
 </extension>
</plugin>
```

XSLT Transformer Plugin Extension

This type of *plugin (on page 3422)* allows you to add an external XSLT transformer *plugin*.

The name of the *plugin* is ***Transformer*** and it makes it easier to contribute your own implementation of the *XSLT Processor*. After the plugin is installed, you can create a new XML transformation with XSLT scenario *(on page 1504)* and select your external XSLT engine from **Transformer** drop-down menu in the **XSLT** tab.

To create an XSLT integration project, follow these steps:

- Copy the `oxygen.jar` file from *`[OXYGEN_INSTALL_DIR]/lib`* to the `lib` folder of your project.
- Copy the jars of your transformer to the `lib` folder of your project.
- Implement the `ro.sync.exml.plugin.transform.XSLTTransformerPluginExtension` interface.
- In the *plugin* descriptor file, define the `<extension>` element that points to the implementation of your classes:

  ```
  <extension type="Transformer" class="my.xslt.plugin.extension"/>
  ```

Validator Plugin Extension

This type of *plugin (on page 3422)* allows you to add an external validation engine from a *plugin*.

The name of the *plugin* extension is *DocumentValidator* and it makes it possible to contribute your own implementation of a validation engine. After the plugin is installed, if you create a new validation scenario or edit an existing validation scenario to add a validation stage, you will find the name of the new engine contributed by the plugin in the **Validation Engine** combo box.

To create a plugin that implements the validator extension:

1. Implement the *ro.sync.exml.plugin.validator.ValidatorPluginExtension* interface in your plugin's libraries.
2. In the *plugin* descriptor file, define the `<extension>` element that points to the implementation of your classes:

   ```
   <extension type="DocumentValidator" class="my.validator.plugin.extension"/>
   ```

Saxon XSLT Transformer Plugin Extension

This type of *plugin (on page 3422)* allows you to add an external Saxon XSLT transformer *plugin*.

The name of the *plugin* is ***Transformer*** and it makes it easier to contribute your own implementation of the *Saxon XSLT Processor*. After the plugin is installed, you can create a new XML transformation with XSLT scenario *(on page 1504)* and select your external Saxon engine from **Transformer** drop-down menu in the **XSLT** tab.

To create an XSLT integration project, follow these steps:

- Copy the `oxygen.jar` file from *`[OXYGEN_INSTALL_DIR]/lib`* to the `lib` folder of your project.
- Copy the *Saxon* jars to the `lib` folder of your project.
- Implement the *ro.sync.exml.plugin.transform.SaxonXSLTTransformerPluginExtension* interface.
- In the *plugin* descriptor file, define the `<extension>` element that points to the implementation of your classes, following example:

```
<extension type="Transformer" class="my.saxon.xslt.plugin.extension"/>
```

An add-on that implements the Saxon XSLT transformer can be found here: Saxon XSLT and XQuery Transformer Add-on *(on page 2721)*. For more information, see the Oxygen XML SDK Add-on Repositories web page.

XQuery Transformer Plugin Extension

This type of *plugin (on page 3422)* allows you to add an external XQuery transformer *plugin*.

The name of the *plugin* is ***XQueryTransformer*** and it makes it easier to contribute your own implementation of the *XQuery Processor*. After the plugin is installed, you can create a new XQuery transformation scenario *(on page 1588)* and select your external XQuery engine from **Transformer** drop-down menu in the **XQuery** tab.

To create an XQuery integration project, follow these steps:

- Copy the `oxygen.jar` file from *`[OXYGEN_INSTALL_DIR]/lib`* to the `lib` folder of your project.
- Copy the jars of your transformer to the `lib` folder of your project.
- Implement the *ro.sync.exml.plugin.transform.XQueryTransformerPluginExtension* interface.
- In the *plugin* descriptor file, define the `<extension>` element that points to the implementation of your classes:

```
<extension type="XQueryTransformer" class="my.xquery.plugin.extension"/>
```

Saxon XQuery Transformer Plugin Extension

This type of *plugin (on page 3422)* allows you to add the Saxon external XQuery transformer *plugin*.

The name of the *plugin* is ***XQueryTransformer*** and it makes it easier to contribute your own implementation of the *Saxon XQuery Processor*. After the plugin is installed, you can create a new XQuery transformation scenario *(on page 1588)* and select your Saxon external XQuery engine from **Transformer** drop-down menu in the **XQuery** tab.

To create an XQuery integration project, follow these steps:

- Copy the `oxygen.jar` file from *`[OXYGEN_INSTALL_DIR]/lib`* to the `lib` folder of your project.
- Copy the *Saxon* jars to the `lib` folder of your project.
- Implement the *ro.sync.exml.plugin.transform.SaxonXQueryTransformerPluginExtension* interface.
- In the *plugin* descriptor file, define the `<extension>` element that points to the implementation of your classes:

```
<extension type="XQueryTransformer" class="my.saxon.xquery.plugin.extension"/>
```

An add-on that implements the Saxon XQuery transformer can be found here: Saxon XSLT and XQuery Transformer Add-on *(on page 2721)*. For more information, see the Oxygen XML SDK Add-on Repositories web page.

Plugin Extensions Designed to Work only in the Text Editing Mode

These *plugin (on page 3422)* extensions operate only when editing documents in the **Text** mode. They are mounted automatically by the application on the contextual menu in the **Plugins** submenu.

The Workspace Access Plugin Extension *(on page 2534)* offers an API that can be used to implement similar functionality for both **Text** and **Author** mode.

General Plugin Extension

This type of *plugin (on page 3422)* allows you to invoke custom code to interact with the workspace in **Text** mode.

This *plugin* is the most general *plugin* type and provides a limited API:

***GeneralPluginExtension* interface**

Intended for general-purpose *plugins*, kind of external tools but triggered from the **Plugins** menu. The implementing classes must provide the method *process(GeneralPluginContext)*, which must provide the *plugin* processing. This method takes as a parameter a *GeneralPluginContext* object.

***GeneralPluginContext* class**

Represents the context in which the general *plugin* extension does its processing. The *getPluginWorkspace()* method allows you access to the workspace of Oxygen XML Editor.

Selection Plugin Extension

This type of *plugin (on page 3422)* allows you to manage selections of text.

A **selection** *plugin* can be applied to both XML and non-XML documents. The *plugin* is started by making a selection in the editor, then selecting the corresponding menu item from the **Plugins** submenu in the contextual menu of **Text** mode.

This *plugin* type provides the following API:

***SelectionPluginExtension* interface**

The context containing the selected text is passed to the extension and the processed result is going to replace the initial selection. The `process(GeneralPluginContext)` method must return a `SelectionPluginResult` object that contains the result of the processing. The *String* value returned by the `SelectionPluginResult` object can include editor variables *(on page 332)* such as *${caret}* and *${selection}*.

***SelectionPluginContext* object**

Represents the context and provides four methods:

- `getSelection()` - Returns a `String` that is the current selection of text.
- `getFrame()` - Returns a `Frame` that is the editing frame.
- `getPluginWorkspace()` - Returns access to the workspace of Oxygen XML Editor.
- `getDocumentURL()` - Returns the URL of the currently edited document.

Related information

Editor Variables *(on page 332)*

Example - Uppercase Plugin

The following *plugin (on page 3422)* is called **UppercasePlugin** and is an example of a Selection *plugin. (on page 2555)*. It is used in Oxygen XML Editor for capitalizing the characters in the current selection. This example consists of two Java classes and the *plugin* descriptor file (`plugin.xml`):

- **UppercasePlugin.java**:

```
package ro.sync.sample.plugin.uppercase;

import ro.sync.exml.plugin.Plugin;
import ro.sync.exml.plugin.PluginDescriptor;

public class UppercasePlugin extends Plugin {
    /**
    * Plugin instance.
    */
    private static UppercasePlugin instance = null;

    /**
    * UppercasePlugin constructor.
    *
    * @param descriptor Plugin descriptor object.
    */
    public UppercasePlugin(PluginDescriptor descriptor) {
        super(descriptor);
```

```
        if (instance != null) {
            throw new IllegalStateException("Already instantiated !");
        }
        instance = this;
    }

    /**
    * Get the plugin instance.
    *
    * @return the shared plugin instance.
    */
    public static UppercasePlugin getInstance() {
        return instance;
    }
}
```

- **UppercasePluginExtension.java**:

```
package ro.sync.sample.plugin.uppercase;

import ro.sync.exml.plugin.selection.SelectionPluginContext;
import ro.sync.exml.plugin.selection.SelectionPluginExtension;
import ro.sync.exml.plugin.selection.SelectionPluginResult;
import ro.sync.exml.plugin.selection.SelectionPluginResultImpl;

public class UppercasePluginExtension implements SelectionPluginExtension {
    /**
    * Convert the text to uppercase.
    *
    *@param  context  Selection context.
    *@return          Uppercase plugin result.
    */
    public SelectionPluginResult process(SelectionPluginContext context) {
        return new SelectionPluginResultImpl(
            context.getSelection().toUpperCase());
    }
}
```

- **plugin.xml**:

```
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin
```

```
    name="UpperCase"
    description="Convert the selection to uppercase"
    version="1.0.0"
    vendor="SyncRO"
    class="ro.sync.sample.plugin.uppercase.UppercasePlugin">
    <runtime>
        <library name="lib/uppercase.jar"/>
    </runtime>
    <extension type="selectionProcessor"
     class="ro.sync.sample.plugin.uppercase.UppercasePluginExtension"/>
</plugin>
```

Document Plugin Extension

This type of *plugin (on page 3422)* allows you to manage the current document.

The **document** *plugin* type can only be applied to an XML document. It can modify the current document that is received as a callback parameter.

The *plugin* is started by selecting the corresponding menu item from the **Plugins** submenu in the contextual menu of **Text** mode. It provides the following API:

***DocumentPluginExtension* interface**

Receives the context object containing the current document. The *process(GeneralPluginContext)* method can return a *DocumentPluginResult* object containing a new document.

***DocumentPluginContext* object**

Represents the context and provides three methods:

- **getDocument()** - Returns a `javax.swing.text.Document` object that represents the current document.
- **getFrame()** - Returns a `java.awt.Frame` object that represents the editing frame.
- **getPluginWorkspace()** - Returns access to the workspace of Oxygen XML Editor.

How to Write a CMS Integration Plugin

To have a complete integration between Oxygen XML Editor and a CMS, you usually have to write a *plugin (on page 3422)* that combines the following two available *plugin* extensions:

- Workspace Access *(on page 2534)*
- Custom protocol *(on page 2563)*

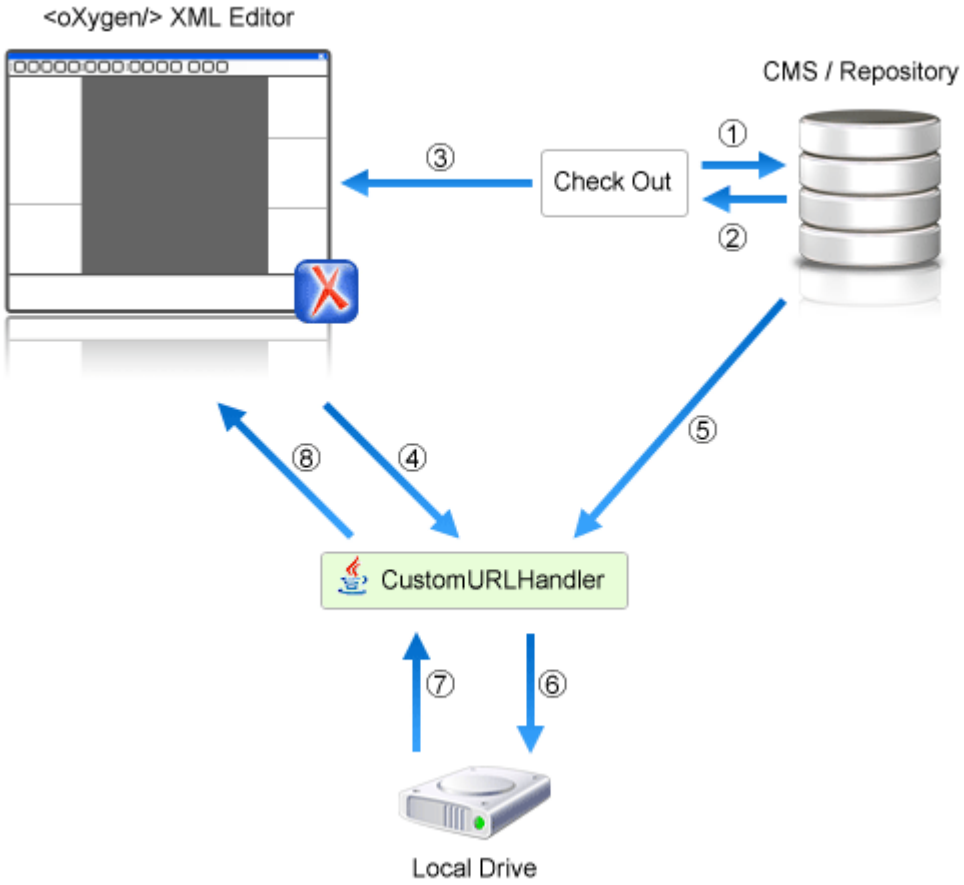
The usual set of requirements for an integration between Oxygen XML Editor and the CMS are as follows:

1. Contribute to the Oxygen XML Editor toolbars and main menu with your custom **Check Out** and **Check In** actions:
   - **Check Out** triggers your custom dialog boxes that allow you to browse the remote CMS and choose the resources you want to open.
   - **Check In** allows you to send the modified content back to the server.

   You can use the **Workspace Access** *plugin extension* (and provided sample Java code) for all these operations.
2. When **Check Out** is called, use the Oxygen XML Editor API to open your custom URLs (URLs created using your custom protocol). It is important to implement and use a **Custom Protocol** extension to be notified when the files are opened and saved and to be able to provide the content for the relative references the files may contain to Oxygen XML Editor. Your custom *java.net.URLStreamHandler* implementation checks out the resource content from the server, stores it locally and provides its content. Sample **Check Out** implementation:

```
  /**
   * Sample implementation for the "Check Out" method.
   *
   * @param pluginWorkspaceAccess (Workspace Access plugin).
   * @throws MalformedURLException
   */
    private void checkOut(StandalonePluginWorkspace pluginWorkspaceAccess)
throws MalformedURLException {
    //TODO Show the user a custom dialog box for browsing the CMS
    //TODO after user selected the resource create a URL with a custom protocol
    //which will uniquely map to the resource on the CMS using the URLHandler
    //something like:
    URL customURL = new URL("mycms://host/path/to/file.xml");
    //Ask Oxygen to open the URL
    pluginWorkspaceAccess.open(customURL);
    //Oxygen will then your custom protocol handler to provide the contents for
    //the resource "mycms://host/path/to/file.xml"
    //Your custom protocol handler will check out the file in a temporary
    //directory, for example, and provide the content from it.
    //Oxygen will also pass through your URLHandler if you have any relative
    //references which need to be opened/obtained.
  }
```

Figure 620. Check Out Process Diagram



The phases are:

- 1 - Browse CMS repository
- 2 - User chooses a resource
- 3 - Use API to open custom URL: `mycms://path/to/file.xml`
- 4 - Get content of URL: `mycms://path/to/file.xml`
- 5 - Get content of resource
- 6 - Store on disk for faster access
- 7 - Retrieve content from disk if already checked out
- 8 - Retrieved content

3. Contribute a special **Browse CMS** action to every dialog box in Oxygen XML Editor where a URL can be chosen to perform a special action (such as the **Reuse Content** or **Insert Image** action). Sample code:

```
      //Add an additional browse action to all dialog boxes/places
      //where Oxygen allows selecting a URL.
      pluginWorkspaceAccess.addInputURLChooserCustomizer
(new InputURLChooserCustomizer() {
        public void customizeBrowseActions
(List<Action> existingBrowseActions, final InputURLChooser chooser) {
          //IMPORTANT, you also need to set a custom icon on the action
          //for situations when its text is not used for display.
```

```
          Action browseCMS = new AbstractAction("CMS") {
            public void actionPerformed(ActionEvent e) {
              URL chosenResource = browseCMSAndChooseResource();
              if (chosenResource != null) {
                try {
                  //Set the chosen resource in the combo box chooser.
                  chooser.urlChosen(chosenResource);
                } catch (MalformedURLException e1) {
                  //
                }
              }
            }
          };
          existingBrowseActions.add(browseCMS);
        }
      });
...
```

When inserting references to other resources using the actions already implemented in Oxygen XML Editor, the reference to the resource is made by default relative to the absolute location of the edited XML file. You can gain control over the way that the reference is made relative for a specific protocol like this:

```
      //Add a custom relative reference resolver for your custom protocol.
      //Usually when inserting references from one URL to another Oxygen
      //makes the inserted path relative.
      //If your custom protocol needs special relativization techniques then
      //it should set up a custom relative
      //references resolver to be notified when resolving needs to be done.
      pluginWorkspaceAccess.addRelativeReferencesResolver(
          //Your custom URL protocol that you already have a
          //custom URLStreamHandlerPluginExtension set up.
          "mycms",
          //The relative references resolver
          new RelativeReferenceResolver() {
        public String makeRelative(URL baseURL, URL childURL) {
          //Return the referenced path as absolute for example.
          //return childURL.toString();
          //Or return null for the default behavior.
          return null;
        }
      });
...
```

4. Write the `plugin.xml` descriptor file. Your *plugin* combines the two extensions using a single set of libraries. The descriptor would look like this:

```
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin
 name="CustomCMSAccess"
 description="Test"
 version="1.0.0"
 vendor="ACME"
 class="custom.cms.CMSAccessPlugin">
 <runtime>
  <library name="lib/cmsaccess.jar"/>
 </runtime>
 <!--Access to add actions to the main menu and toolbars or to add custom views.-->
 <!--See the "CustomWorkspaceAccessPluginExtension" Java sample for more details-->
 <extension type="WorkspaceAccess"
  class="custom.cms.CustomWorkspaceAccessPluginExtension"/>
 <!--The custom URL handler that will communicate with the CMS implementation-->
 <!--See the "CustomProtocolURLHandlerExtension" Java sample for more details-->
 <extension type="URLHandler"
  class="custom.cms.CustomProtocolURLHandlerExtension"/>
</plugin>
```

5. Create a `cmsaccess.jar` *JAR (on page 3420)* archive containing your implementation classes.
6. Copy your new *plugin* directory in the `plugins` subfolder of the Oxygen XML Editor install folder (for example, *`[OXYGEN_INSTALL_DIR]`*`/plugins/myPlugin`) and start Oxygen XML Editor.

https://github.com/oxygenxml/oxygen-cmis-plugin

https://github.com/axxepta/project-argon

Class Loading Issues

It is possible that the Java libraries you have specified in the *plugin* libraries list conflict with the ones already loaded by Oxygen XML Editor. To instruct the *plugin* to prefer its libraries over the ones used by Oxygen XML Editor, you can add the following attribute on the `<plugin>` root element: `classLoaderType="preferReferencedResources"` from the `plugin.xml` descriptor file.

A **Late Delegation Class Loader** (the main class loader in Oxygen XML Editor) is a `java.net.URLClassLoader` extension that prefers to search classes in its own libraries list and only if a class is not found there to delegate to the parent class loader.

The main Oxygen XML Editor Class Loader uses as libraries all *JARS* specified in the *`[OXYGEN_INSTALL_DIR]`*`\lib` directory. Its parent class loader is the default JVM Class loader. For each *plugin* instance, a separate class loader is created having as parent the Oxygen XML Editor Class Loader.

The *plugin* class loader can be either a standard `java.net.URLClassLoader` or a `LateDelegationClassLoader` (depending on the attribute `classLoaderType` in the `plugin.xml`). Its parent class loader is always the Oxygen XML Editor `LateDelegationClassLoader`.

If you experience additional problems, such as:

```
java.lang.LinkageError: ClassCastException:
attempting to cast
jar:file:/C:/jdk1.6.0_06/jre/lib/rt.jar!/
javax/xml/ws/spi/Provider.class
tojar:file:/D:/Program
 Files/Oxygen XML Editor
 12/plugins/wspcaccess/../../xdocs/lib/jaxws/
jaxws-api.jar!/javax/xml/ws/spi/Provider.class
 at javax.xml.ws.spi.Provider.provider(
Provider.java:94) at
 javax.xml.ws.Service.<init>(Service.java:56)
.....................................
```

The cause could be the fact that some classes are instantiated using the context class loader of the current thread. The most straightforward fix is to write your code in a *try/finally* statement:

```
ClassLoader oldClassLoader =
    Thread.currentThread().getContextClassLoader();
try {
  //This is the implementation of the
  //WorkspaceAccessPluginExtension plugin interface.
  Thread.currentThread().setContextClassLoader(
    CustomWorkspaceAccessPluginExtension.
      this.getClass().getClassLoader());
  //WRITE YOUR CODE HERE
} finally {
  Thread.currentThread().
   setContextClassLoader(oldClassLoader);
}
```

How to Write A Custom Protocol Plugin

To create a custom protocol *plugin (on page 3422)*, follow these steps:

1. Write the handler class for your protocol that implements the *java.net.URLStreamHandler* interface. Be careful to provide ways to encode and decode the URLs of your files.
2. Write the *plugin* class by extending *ro.sync.exml.plugin.Plugin*.
3. Write the *plugin* extension class that implements the *ro.sync.exml.plugin.urlstreamhandler.URLStreamHandlerPluginExtension* interface.

It is necessary that the *plugin* extension for the custom protocol implements the *URLStreamHandlerPluginExtension* interface. Without it, you cannot use your *plugin*, because Oxygen XML Editor is not able to find the protocol handler.

You can choose also to implement the *URLChooserPluginExtension* interface. It allows you to write and display your own customized dialog box for selecting resources that are loaded with the custom protocol.

An implementation of the extension *URLHandlerReadOnlyCheckerExtension* allows you to:

- Mark a resource as read-only when it is opened.
- Switch between marking the resource as read-only and read-write while it is edited.

It is useful when opening and editing CMS resources.

4. Write the `plugin.xml` descriptor file.
   Remember to set the name of the *plugin* class to the one from the second step and the *plugin* extension class name with the one you have chosen at step 3.
5. Create a *JAR (on page 3420)* archive with all these files.
6. Create a custom plugin folder inside the **plugins** folder (for example, *`[OXYGEN_INSTALL_DIR]`*`/plugins/myPlugin`) that contains your new *plugin*.

How to Share a Class Loader Between a Framework and Plugin

In some cases you may need to extend the functionality of Oxygen XML Editor both through a *framework (on page 3420)* and through a *plugin (on page 3422)*. Normally, a *framework* and a *plugin* both run in their own private classloader. If the *framework* and the *plugin* use the same JAVA extensions/classes, it is recommended that they share the same classloader. This way, the common classes are loaded by only one *Class Loader* and they will both use the same static objects and have the ability to cast objects between one another.

To do this, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, select the document type, go to the **Classpath** tab, and in the **Use parent classloader from plugin with ID** fields introduce the ID of the *plugin*. This ID is declared in the configuration file of the *plugin (on page 2531)*.

If you have created the framework using a *Framework Extension Script*, then edit the script and specify the plugin ID on the classpath *(on page 2253)*.

Important:
The shared classes must be specified only in the configuration files of the *plugin*, and not in the configuration file and the document type class path at the same time.

Packing and Deploying Plugins as Add-ons

In Oxygen XML Editor, a *plugin* can be packed and deployed as an *add-on* to provide additional functionality to the application.

Packing a Plugin as an Add-on

This procedure is suitable for developers who want a better control over the *add-on (on page 3422)* package or those who want to automate some of the steps:

1. Pack the *plugin (on page 3422)* as a ZIP file or a *Java Archive (on page 3420)*. Note that you should pack the entire root directory not just its contents.
2. **[Optional]** If you created a *Java Archive* at the previous step, digitally sign the package. You will need a certificate signed by a trusted authority. To sign the *JAR*, you can either use the *jarsigner* command-line tool inside Oracle's Java Development Kit (`[JDK_DIR]/bin/jarsigner.exe`) or if you are working with *Apache Ant (on page 3417)*, you can use the *signjar* task (a front for the *jarsigner* command-line tool). The benefit of having a signed add-on is that you can verify the integrity of the add-on issuer.
   If you do not have such a certificate, you can generate one yourself using the *keytool* command-line utility.

   > **Note:**
   > This approach is recommended for tests since anyone can create a self-signed certificate.

3. Create a descriptor file. You can use a template that Oxygen XML Editor provides by going to **File > New** and selecting the **Oxygen add-ons update site** template. The products the add-on is compatible with can be specified in the template. Once deployed, this descriptor file is referenced as *update site*.

Deploying an Add-on

To deploy an add-on, copy the `ZIP` or *Java Archive (on page 3420)* file and the descriptor file to an HTTP server. The URL to this location serves as the *Update Site URL*.

Related Information:
Packing and Deploying Frameworks as Add-ons *(on page 2407)*
Oxygen XML Add-on Repositories

Testing Plugins and Java Extensions

In the various procedures for creating a *plugin (on page 3422)*, you are usually instructed to copy your plugin folder to the *`[OXYGEN_INSTALL_DIR]`*`/plugins/` directory. If you want to test the code in your plugin without copying it to that folder, follow this procedure:

1. Create a file called `plugin.redirect` that contains the full file path references to your project (for example, `C:\Users\john_doe\Documents\sample-plugin-folder`).
2. Save that file in any folder (for example, called `sample_test_folder`) inside the *`[OXYGEN_INSTALL_DIR]`*`/plugins/` directory.

   Step Result: Oxygen XML Editor will automatically load the plugin from your project location.
3. Now you can modify the Java code, the IDE will automatically compile it, and if the **plugin.xml** file has a classpath reference to the compiled classes folder, you can restart Oxygen XML Editor and test your changes.

Creating and Running Automated Tests

If you have developed complex custom *plugins (on page 3422)* or *frameworks (on page 3420)* (document types), the best way to test your implementation and ensure that further changes will not interfere with the current behavior is to make automated tests for your customization.

An Oxygen XML Editor standalone installation includes a main `oxygen.jar` library located in the *`[OXYGEN_INSTALL_DIR]`*. That *JAR (on page 3420)* library contains a base class for testing developer customizations named: `ro.sync.exml.workspace.api.PluginWorkspaceTCBase`.

To develop *JUnit* tests for your customizations using the Eclipse workbench, follow these steps:

1. Create a new Eclipse Java project and copy the entire contents of the *`[OXYGEN_INSTALL_DIR]`* folder to the new project under the `oxygen` sub-directory.
2. Add all *JAR* libraries present in the `./oxygen/lib` directory to the **Java Build Path**->**Libraries** tab. Make sure that the main *JAR* library `oxygen.jar` or `oxygenAuthor.jar` is the first one in the Java classpath by moving it up in the **Order and Export** tab.
3. Click **Add Library** and add the *JUnit* and *JFCUnit* libraries.
4. Create a new Java class that extends `ro.sync.exml.workspace.api.PluginWorkspaceTCBase`.
5. Pass the following parameters to the constructor of the super class:
   - **File installationFolder** - The file path to the main application installation directory. If not specified, it defaults to the folder where the test is started. According to step 1, it should be `oxygen`.
   - **File frameworksFolder** - The file path to the `frameworks` directory. It can point to a custom *framework* directory where it resides. According to step 1, it should be `oxygen/frameworks`.
   - **File pluginsFolder** - The file path to the `plugins` directory. It can point to a custom *plugin* directory where it resides. According to step 1, it should be `oxygen/plugins`.
   - **File optionsFolder** - The folder that contains the application options. If not specified, the application will auto-detect the location based on the started product ID.
   - **String licenseKey** - The license key used to license the test class.
   - **int productID** - The ID of the product and should be one of the following: `PluginWorkspaceTCBase.XML_AUTHOR_PRODUCT`, `PluginWorkspaceTCBase.XML_EDITOR_PRODUCT`, or `PluginWorkspaceTCBase.XML_DEVELOPER_PRODUCT`.

6. Create test methods that use the API in the base class to open XML files and perform various actions on them. Your test class could look something like this:

```
public class MyTestClass extends PluginWorkspaceTCBase {

/**
 * Constructor.
 */
public MyTestClass() throws Exception {
    super(null, new File("frameworks"), new File("plugins"), null,
"------START-LICENSE-KEY------\n" +
    "\n" +
    "Registration_Name=Developer\n" +
    "\n" +
    "Company=\n" +
    "\n" +
    "Category=Enterprise\n" +
    "\n" +
    "Component=XML-Editor, XSLT-Debugger, Saxon-SA\n" +
    "\n" +
    "Version=14\n" +
    "\n" +
    "Number_of_Licenses=1\n" +
    "\n" +
    "Date=09-04-2012\n" +
    "\n" +
    "Trial=31\n" +
    "\n" +
    "SGN=MCwCFGNoEGJSeiC3XCYIyalvjzHhGhhqAhRNRDpEu8RIWb8icCJO7HqfVP4++A\\=\\=\n" +
    "\n" +
"-------END-LICENSE-KEY-------",
   PluginWorkspaceTCBase.XML_AUTHOR_PRODUCT);
}

/**
  * <p><b>Description:</b> TC for opening a file and using a bold operation</p>
  * <p><b>Bug ID:</b> EXM-20417</p>
  *
  * @author radu_coravu
  *
  * @throws Exception
  */
public void testOpenFileAndBoldEXM_20417() throws Exception {
```

```
    WSEditor ed = open(new File
("D:/projects/eXml/test/authorExtensions/dita/sampleSmall.xml").toURL());
    //Move caret
    moveCaretRelativeTo("Context", 1, false);

    //Insert <b>
    invokeAuthorExtensionActionForID("bold");
    assertEquals("<?xml version=\"1.0\" encoding=\"utf-8\"?>\n" +
        "<!DOCTYPE task PUBLIC \"-//OASIS//DTD DITA Task//EN\" \"task.dtd\">\n" +
        "<task id=\"taskId\">\n" +
        "    <title>Task <b>title</b></title>\n" +
        "    <prolog/>\n" +
        "    <taskbody>\n" +
        "        <context>\n" +
        "            <p>Context for the current task</p>\n" +
        "        </context>\n" +
        "        <steps>\n" +
        "            <step>\n" +
        "                <cmd>Task step.</cmd>\n" +
        "            </step>\n" +
        "        </steps>\n" +
        "    </taskbody>\n" +
        "</task>\n" +
        "", getCurrentEditorXMLContent());
  }
}
```

Debugging a Plugin Using IntelliJ IDEA

To use *IntelliJ IDEA* to debug problems in the code of a *plugin (on page 3422)* without having to re-bundle the plugin's Java classes in a *JAR (on page 3420)* library, follow these steps:

1. Download and install Oxygen XML Editor.
2. Set up the *Oxygen SDK* following this set of instructions.
3. Create a Java Project (for example, `MyPluginProject`) from one of the sample plugins (for example, the Workspace Access plugin).
4. In the `MyPluginProject` folder, create a folder called `myPlugin`. In this new folder, copy the `plugin.xml` file from the sample plugin. Modify the added `plugin.xml` to add a library reference to the directory where IntelliJ IDEA copies the compiled output. To find out where this directory is located, go to **File > Project Structure**. Then select the **Modules** category and inspect the value of the **Output path** text box from the **Path** tab.

Example: If the output path is `C:/Users/myUser/Documents/MyPluginProject/target/classes`, then in the `plugin.xml`, you need to add the following library reference in the *runtime* element:

```
<library name="../target/classes"/>
```

5. Copy the `plugin.dtd` from the *`[OXYGEN_INSTALL_DIR]`*`/plugins` folder in the root `MyPluginProject` folder.
6. In the `MyPluginProject` dependences (**File > Project Structure > Modules > Dependences**), add external *JAR* references to all the *JAR* libraries in the *`[OXYGEN_INSTALL_DIR]`*`/lib` folder. Now your `MyPluginProject` should compile successfully.
7. In IntelliJ IDEA, create a new *Java Application* configuration for debugging (**Run > Edit Configurations... > + > Application**). Set the **Main class** box to `ro.sync.exml.Oxygen` and add the following code snippet in the **VM options** input box, making sure that the path to the `plugins` directory is the correct one:

```
-Dcom.oxygenxml.app.descriptor=ro.sync.exml.EditorFrameDescriptor
-Dcom.oxygenxml.editor.plugins.dir=D:\projects\MyPluginProject
```

8. Add a *breakpoint (on page 2241)* in the source of one of your Java classes.
9. Debug the created configuration. When the code reaches your *breakpoint (on page 2240)*, the IntelliJ IDEA debugging view should take over.

Debugging a Plugin Using the Eclipse Workbench

To use the Eclipse workbench to debug problems in the code of a *plugin (on page 3422)* without having to re-bundle the plugin's Java classes in a *JAR (on page 3420)* library, follow these steps:

1. Download and install Oxygen XML Editor.
2. Set up the *Oxygen SDK* following this set of instructions.
3. Create an Eclipse Java Project (for example, `MyPluginProject`) from one of the sample plugins (for example, the Workspace Access plugin).
4. In the `MyPluginProject` folder, create a folder called `myPlugin`. In this new folder, copy the `plugin.xml` file from the sample *plugin*. Modify the added `plugin.xml` to add a library reference to the directory where Eclipse copies the compiled output. To find out where this directory is located, invoke the contextual menu of the project (in the **Project** view *(on page 413)*), and go to **Build Path > Configure Build Path**. Then inspect the value of the **Default output folder** text box.

   Example: If the compiled output folder is `classes`, then in the `plugin.xml`, you need to add the following library reference:

   ```
   <library name="../classes"/>
   ```

5. Copy the `plugin.dtd` from the *`[OXYGEN_INSTALL_DIR]`*`/plugins` folder in the root `MyPluginProject` folder.
6. In the `MyPluginProject` build path, add external *JAR* references to all the *JAR* libraries in the *`[OXYGEN_INSTALL_DIR]`*`/lib` folder. Now your `MyPluginProject` should compile successfully.

7. In the Eclipse IDE, create a new *Java Application* configuration for debugging. Set the **Main class** box to `ro.sync.exml.Oxygen`. Click the **Arguments** tab and add the following code snippet in the **VM arguments** input box, making sure that the path to the `plugins` directory is the correct one:

   ```
   -Dcom.oxygenxml.app.descriptor=ro.sync.exml.EditorFrameDescriptor
   -Dcom.oxygenxml.editor.plugins.dir=D:\projects\MyPluginProject
   ```

   In the **Dependencies** tab, you should only add dependencies to two JAR libraries: *[OXYGEN_INSTALL_DIR]*`/lib/oxygen.jar` and *[OXYGEN_INSTALL_DIR]*`/lib/oxygen-basic-utilities.jar`.

8. Add a *breakpoint (on page 2241)* in the source of one of your Java classes.
9. Debug the created configuration. When the code reaches your *breakpoint (on page 2240)*, the Eclipse IDE debugging perspective should take over.

Debugging an Oxygen SDK Extension Using the Eclipse Workbench

To use the Eclipse workbench to debug problems in the code of an *extension (on page 3422)* without having to bundle its Java classes in a *JAR (on page 3420)* library, perform the following steps:

1. Download and install Oxygen XML Editor.
2. Create an Eclipse Java Project (for example, `MySDKProject`) with the corresponding Java sources (for example, a custom implementation of the *ro.sync.ecss.extensions.api.StylesFilter* interface).
3. In the Project build path, add external *JAR* references to all the *JAR* libraries in the *[OXYGEN_INSTALL_DIR]*`/lib` folder. In the build path **Order and Export** panel, make sure that the `oxygen.jar` entry is before all other libraries. Now your Project should compile successfully.
4. Start the standalone version of Oxygen XML Editor from the *[OXYGEN_INSTALL_DIR]* and in the **Document Type Association** preferences page *(on page 145)*, edit the document type (for example, **DITA**) to open the **Document Type** configuration dialog box *(on page 147)*. In the **Classpath** tab, add a reference to your Project's `classes` directory and in the **Extensions** tab, select your custom *StylesFilter* extension as a value for the **CSS styles filter** property. Close the application to save your changes.

5. Create a new Java Application configuration for debugging. The Main Class should be `ro.sync.exml.Oxygen`. The given VM Arguments should be:

   ```
   -Dcom.oxygenxml.app.descriptor=ro.sync.exml.EditorFrameDescriptor
   ```

6. Add a *breakpoint (on page 2241)* in one of the source Java classes.
7. Debug the created configuration. When the code reaches your *breakpoint (on page 2240)*, the Eclipse IDE debugging perspective should take over.

Disabling a Plugin

To disable a *plugin (on page 3422)*, use one of the following two methods:

- Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Plugins**, and deselect the *plugin* that you want to disable.
- Create an empty file called `plugin.disable` next to the *plugin* configuration file (`plugin.xml`). The *plugin* will be disabled and will no longer be loaded by the application on startup.

> **Note:**
> This is useful if you want to temporarily stop work on a *plugin* and use the application without it.

Oxygen XML Author Component

The Oxygen XML Author Component was designed as a subset of Oxygen XML Editor that can be integrated into another application under the terms of the Oxygen XML Editor SDK agreement to provide functionality for editing and authoring XML documents. The component can be embedded in a third-party standalone Java application to provide WYSIWYG-like XML editing directly in your application.

More information about the setup for the Oxygen XML Author Component can be found on the Oxygen SDK page.

Licensing

The licensing terms and conditions for the Oxygen XML Author Component are defined in the ***Oxygen SDK License Agreement***. To obtain the licensing terms and conditions and other licensing information as well, you can also contact the support team at **support@oxygenxml.com**. You may also obtain a free of charge evaluation license key for development purposes, subject to registration. Any deployment of an application developed using the Oxygen XML Author Component is also subject to the terms of the SDK agreement.

There are two main categories of Oxygen XML Author Component integrations:

- **Integration for internal use:**

  You develop an application that embeds the *Author Component* to be used internally (in your company or by you). You can buy and use previously purchased Oxygen XML Editor floating licenses to enable the runtime usage of the Oxygen XML Author Component as it was integrated into the application.

- **Integration for external use:**

  Using the Oxygen XML Author Component, you create an application that you distribute to other users outside your company (with a CMS for example). In this case, you should apply for a Value Added Reseller (VAR) partnership by contacting the **Oxygen Sales Team** (https://www.oxygenxml.com/sales_support.html).

From a technical point of view, the Oxygen XML Author Component provides the Java API to:

- **Inject floating license server details in the Java code:**

  The following link provides details about how to configure an HTTP floating license server: https://www.oxygenxml.com/license_server.html#floating_license_servlet.

```
AuthorComponentFactory.getInstance().init(frameworkZips,
  optionsZipURL, codeBase, appID,
      //The servlet URL
      "http://www.host.com/servlet",
      //The HTTP credentials user name
      "userName",
      //The HTTP credentials password
      "password");
...
```

Related Information:
https://www.oxygenxml.com/sdk_agreement.html

Installation Requirements

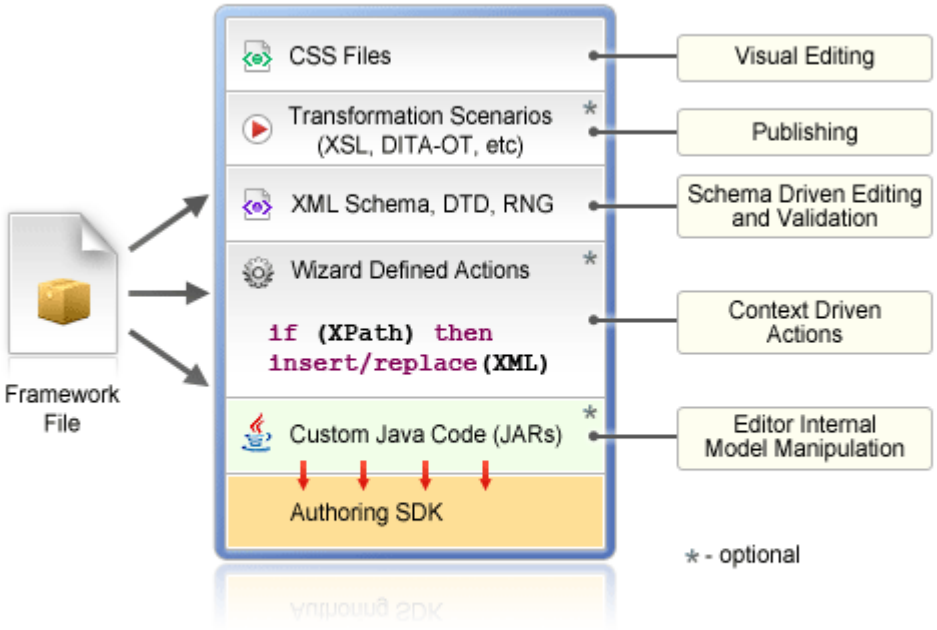
Running the Oxygen XML Author Component embedded in a third-party Java/Swing application requires:

- Oracle Java version 11 or 17.
- At least 100 MB disk space and 100MB free memory.

Customization

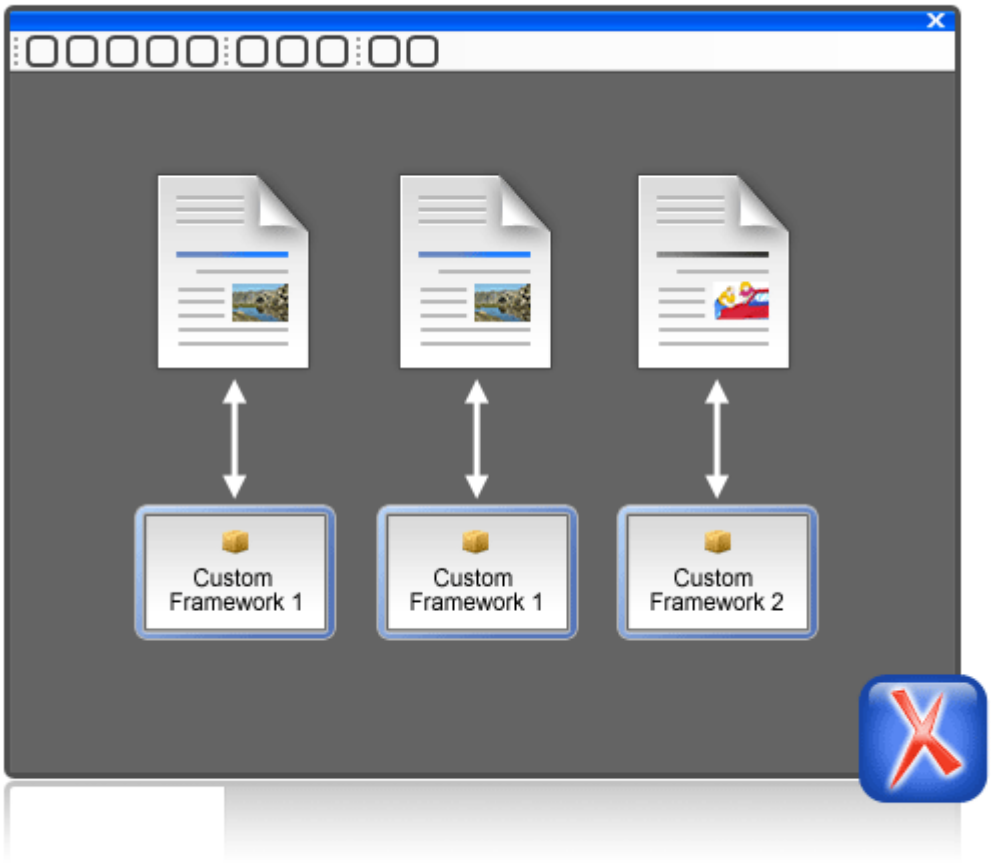
For a special type of XML, you can create a custom *framework (on page 3420)* (which also works in a standalone version of Oxygen XML Editor). Oxygen XML Editor already has *frameworks* for editing DocBook, DITA, TEI, and so on. Their sources are available in the Oxygen SDK. This custom *framework* is then packed in a zip archive and used to deploy the component.

Figure 621. Components of a Custom Framework



Multiple *frameworks* can coexist in the same component and can be used at the same time for editing XML documents.

Figure 622. Multiple Frameworks



You can add on your custom toolbar all actions available in the standalone Oxygen XML Editor application for editing in the **Author** mode. You can also add custom actions defined in the *framework* customized for each XML type.

The Oxygen XML Author Component can also provide the **Outline** *(on page 549)*, **Model** *(on page 555)*, **Elements** *(on page 643)*, and **Attributes** *(on page 638)* views, which can be added to your own developed containers.

The main entry point for the Oxygen XML Author Component Java API is the *AuthorComponentFactory* class.

Related Information:

Creating and Configuring Custom Frameworks *(on page 2248)*

Oxygen XML Author Component *(on page 2571)*

AuthorComponentFactory API

Example - Customizing the DITA Framework

If you look inside the `bundle-frameworks\oxygen-frameworks` folder distributed with the Oxygen XML Author Component sample project, it contains a `frameworks` folder. Customizations that affect the

framework configuration for the component should first be done in a standalone installation of Oxygen XML Editor.

The Oxygen XML Editor installation also includes a `frameworks` folder that contains the `dita` *framework* located in *`[OXYGEN_INSTALL_DIR]`*`\frameworks\dita`. The `dita` *framework* contains a bundled **DITA-OT** distribution that contains the DTDs used for DITA editing. If your DTD specialization is a DITA-OT plugin, it should be installed *(on page 2533)* in the *`DITA-OT-DIR`*`\plugins` folder.

To make changes to the DITA *framework* configuration, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, and edit or extend the framework. These changes will affect the *`[OXYGEN_INSTALL_DIR]`*`\frameworks\dita\dita.framework` configuration file.

After you do this, you can re-pack the Oxygen XML Author Component following the instructions from the README.html file located in the Oxygen XML Author Component sample project. The *Author Component* sample project and the Oxygen XML Editor standalone installation should be of the same version.

Related Information:
Framework and Author Mode Customization *(on page 2248)*

Packing a Fixed Set of Options

The Oxygen XML Author Component shares a common internal architecture with the standalone application, although it does not have **Preferences** dialog boxes. However, the *Author Component* can be configured to use a fixed set of user options on startup.

The sample project contains a module called `bundle-options`. The module contains a file called `options.xml` in the `oxygen-options` folder. Such an XML file can be obtained by exporting the options to an XML format from an installation of Oxygen XML Editor.

To create an *options file* in the Oxygen XML Editor:

- Make sure the options that you want to set are not stored at project level *(on page 320)*.
- Set the values you want to impose as defaults in the Preferences pages *(on page 131)*.
- Select **Options > Export Global Options**.

Adding MathML support in the Oxygen XML Author Component

By default, the Oxygen XML Author Component does not come with the libraries necessary for viewing and editing MathML equations in the **Author** mode. You can view and edit MathML equations either by adding support for JEuclid *(on page 2575)* or by adding support for MathFlow *(on page 2576)*.

Adding MathML Support Using JEuclid

By default, the *JEuclid* library is excluded from the *Oxygen SDK* artifact dependencies. To enable it, comment the following lines in the `pom.xml` file:

```
<exclusion>
    <artifactId>jeuclid-core</artifactId>
    <groupId>net.sourceforge.jeuclid</groupId>
</exclusion>
```

To edit specialized DITA Composite documents with MathML content, include the entire MathML2 *framework* directory (for example, the default location is: *[OXYGEN_INSTALL_DIR]/frameworks/mathml2*) in the *frameworks (on page 3420)* bundled with the component in the `bundle-frameworks` module. This directory is used to solve references to MathML DTDs.

Adding MathML Support Using MathFlow (Deprecated)

Note:
The *MathFlow* editor integration has been marked as deprecated and in future versions, it will be replaced with a new *MathType* integration developed by *Wiris*.

In the `pom.xml` file, add dependencies to the following additional libraries used by the MathFlow library to parse MathML equations:

1. `MFComposer.jar`
2. `MFExtraSymFonts.jar`
3. `MFSimpleEditor.jar`
4. `MFStructureEditor.jar`
5. `MFStyleEditor.jar`

Note:
For MathFlow 2.1, all of these *JAR (on page 3420)* files are packaged into one file called `MathFlow.jar`.

You can reference these additional libraries from the MathFlow SDK as in the example below:

```
<dependency>
    <groupId>com.dessci</groupId>
    <artifactId>MFComposer</artifactId>
    <version>1.0.0</version>
    <scope>system</scope>
    <systemPath>${MathFlowSDKDir}/lib/MFComposer.jar</systemPath>
</dependency>
```

In addition, you must obtain fixed MathFlow license keys for editing and composing *MathML* equations and register them using these API methods: `AuthorComponentFactory.setMathFlowFixedLicenseKeyForEditor` and `AuthorComponentFactory.setMathFlowFixedLicenseKeyForComposer`.

To edit specialized DITA Composite with *MathML* content, include the entire `[OXYGEN_INSTALL_DIR]/frameworks/mathml2` Mathml2 *framework* directory in the *frameworks (on page 3420)* bundled with the component in the `bundle-frameworks` module. This directory is used to solve references to *MathML* DTDs.

More documentation is available on the *Wiris MathFlow* website.

Adding Support to Insert References from a WebDAV Connection

Predefined actions that insert references, such as the **Insert Image** action, includes a URL chooser field with a drop-down menu that allows you to select a **Browse Data Source Explorer** action. This action opens the **Data Source Explorer** *(on page 2133)* that allows you to view a WebDAV connection.

To use a WebDAV connection in the Oxygen XML Author Component, follow these steps:

1. Open a standalone Oxygen XML Editor 26.1 and configure a WebDAV connection *(on page 2179)*.
2. Pack the fixed set of options *(on page 2575)* from the standalone application to use them with the Oxygen XML Author Component project.
3. In the Oxygen XML Author Component, the defined connection still does not work when expanded because the additional *JAR* libraries used to browse the WebDAV repository are missing. By default, the `httpclient` dependency of the *Oxygen SDK* artifact is excluded. You can enable it by commenting the following lines:

   ```
   <exclusion>
       <artifactId>httpclient</artifactId>
       <groupId>org.apache.httpcomponents</groupId>
   </exclusion>
   ```

   If you want to have multiple WebDAV connection URLs, user names, and passwords (depending on the user who started the component), you can use a more flexible approach by using the following API:

   ```
       //DBConnectionInfo(String id, String driverName, String url, String user,
   String passwd, String host, String port)
       DBConnectionInfo info = new DBConnectionInfo("WEBDAV", "WebDAV FTP",
   "http://host/webdav-user-root", "userName", "password", null, null);
       AuthorComponentFactory.getInstance().setObjectProperty
   ("database.stored.sessions1", new DBConnectionInfo[] {info});
   ```

Using Plugins with the Oxygen XML Author Component

To bundle Workspace Access *plugins (on page 3422)* that are developed for the standalone application with the Oxygen XML Author Component, follow these steps:

- The `bundle-plugins` module must contain the additional plugin directories in the `dropins` subdirectory. The content must also contain a `plugin.dtd` file. Copy the `plugin.dtd` file from an `[OXYGEN_INSTALL_DIR]\plugins` folder.
- In the class that instantiates the *AuthorComponentFactory* (for example the *ro.sync.ecss.samples.AuthorComponentSample* class), call the methods *AuthorComponentFactory.getPluginToolbarCustomizers()*, *AuthorComponentFactory.getPluginViewCustomizers()*, and *AuthorComponentFactory.getMenubarCustomizers()*, obtain the customizers that have been added by the plugins and call them to obtain the custom swing components that they contribute. There is a commented-out example for this in the *AuthorComponentSample.reconfigureActionsToolbar()* method for adding the toolbar from the **Acrolinx** plugin.

Important:
As the Oxygen XML Author Component is just a subset of the entire application, there is no guarantee that all the functionality of the plugin will work.

Frequently Asked Questions

Installation and Licensing

1. Are there any client requirements beyond the Java VM?

   Oracle Java version 11 or 17. At least 200 MB disk space and 200MB free memory is necessary for the Oxygen XML Author Component.

2. Does the Oxygen XML Author Component support multiple documents being open simultaneously? What are the licensing ramifications?

   A single *AuthorComponentFactory* instance can create multiple *EditorComponentProvider* editors that can then be added and managed by the developer who customizes the component in a Swing *JTabbedPane*. A single license (floating or user-based) is enough for this.

   If you need to run multiple distinct Java processes using the Oxygen XML Author Component, the current floating license model allows for only two concurrent components from the same computer when using the HTTP floating license server. An additional started component will take an extra license seat.

Functionality

1. What graphic formats can be directly rendered in the Oxygen XML Author Component?

   GIF, JPEG, PNG, BMP and SVG.

2. Can links be embedded to retrieve (from the server) and "play" other types of digital assets, such as audio or video files?

You could add listeners to intercept clicks and open the clicked links. This would require a good knowledge of the *Oxygen SDK*. The Oxygen XML Author Component can only render static images (no GIF animations).

3. Does the Oxygen XML Author Component provide methods for uploading ancillary files (new graphics, for instance) to the hosting server?

   No.

4. Does the Oxygen XML Author Component provide any type of autosave functionality?

   By default no, but you could customize it to save its content periodically to a file on disk.

5. Assuming multiple documents can be edited simultaneously, can content be copied, cut, and pasted from one Oxygen XML Author Component "instance" to another?

   Yes.

6. Does the Oxygen XML Author Component support pasting content from external sources (such as a web page or a Microsoft Word document and, if so, to what extent?

   If no customizations are available, the content is pasted as simple text. Customizations are provided for the major *frameworks* (DITA, DocBook, TEI, etc.) that use a conversion XSLT stylesheet to convert HTML content from clipboard to the target XML.

7. Can UTF-8 characters (such as Greeks, mathematical symbols, etc.) be inserted and rendered?

   Any UTF-8 character can be inserted and rendered, provided that the font used for editing supports rendering the characters. The font can be changed by developers but not by the users. When using a logical font (by default, *Serif* for the Oxygen XML Author Component), the JVM will know how to map all characters to glyphs. There is no character map available but you could implement one.

Customization

1. Describe, in general terms, the menus, toolbars, contextual menu options, helper panes, and so on, that are available for the Oxygen XML Author Component out-of-the box.

   You can mount all actions available in the standalone Oxygen XML Editor application on your custom toolbar. This includes custom actions defined in the *framework* customized for each XML type.

   The Oxygen XML Author Component also can provide the **Outline** *(on page 549)*, **Model** *(on page 555)*, **Elements** *(on page 643)*, and **Attributes** *(on page 638)* views that can be added to your own panels.

2. Describe, in general terms, the actions, project resources (for example, DTD/Schema for validation purposes, CSS/XSL for styling, etc.) and typical level of effort that would be required to deploy a Oxygen XML Author Component solution for a customer with a proprietary DTD.

   The **Author** mode internal engine uses CSS to render XML.

For a special type of XML, you can create a custom *framework* (which also works in an Oxygen XML Editor standalone version) that would also contain default schemas and custom actions. A simple *framework* would probably need 2-3 weeks development time. For a complex *framework* with many custom actions, it could take a long time. Oxygen XML Editor has built-in *frameworks* for editing (DocBook, DITA, TEI, etc.) and sources for them are available in the Oxygen SDK.

Multiple *frameworks* can co-exist in the same Oxygen XML Editor instance and can be used at the same time for editing XML documents.

3. Many customers desire a very simplistic interface for contributors (with little or no XML expertise) but a more robust XML editing environment for editors (or other users with more advanced XML expertise). How well does the Oxygen XML Author Component support varying degrees of user interface complexity and capability?

    - *Showing/hiding menus, toolbars, helpers, etc.*

      You assemble all the UI parts from the Oxygen XML Author Component. For example, you could provide two implementations: one for advanced users and one for content authors.

    - *Forcing behaviors (for example, ensuring change tracking (on page 3424) is on and preventing it from being shut down).*

      You could avoid placing the *change tracking* toolbar actions in the UI. You could also use the API to turn *change tracking* ON when the content has been loaded.

    - *Preventing access to "privileged" editor processes (for example, accept/reject changes).*

      You can remove the *change tracking* actions completely in a custom implementation, including the ones from the contextual menu.

    - *Presenting and/or describing XML constructs (for example, tags) in "plain-English".*

      Using our API, you can customize what the Outline view or Breadcrumb displays for each XML tag. You can also customize the in-place content completion list.

    - *Presenting a small subset of the overall XML tag set (rather than the full tag set) for use by contributors (for example, allowing an author to only insert Heading, Para, and inline emphasis).*

      The API allows for a content completion filter that also affects the *Elements* view.

4. Does the Oxygen XML Author Component API provide access to the XML document, for manipulation purposes, using common XML syntax (such as DOM, XPath, etc.)?

   Yes, using the Oxygen XML Author Component API.

5. Can custom dialog boxes be developed and launched to collect information in a "form" (with scripting behind to tag the collection information and embed it in the XML document)?

Yes.

6. Can project resources and customizations be readily shared between the desktop and component versions of your Oxygen XML Author Component product line?

   A *framework* developed for the standalone version of the Oxygen XML Editor application can then be bundled with the Oxygen XML Author Component. For example, you could use the same *framework* that you use in the Oxygen XML Editor standalone distribution.

   A custom editing solution can deploy one or more *frameworks* that can be used at the same time.

Print Document Within the Oxygen XML Author Component

Question

Can a document be printed within the Oxygen XML Author Component?

Answer

You can use the following API method to either print the document content to the printer or to show the Print Preview dialog box, depending on the `preview` parameter value:

```
AuthorComponentProvider.print(boolean preview)
```

Here is the online Javadoc for this method: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/component/AuthorComponentProvider.html#print(boolean)

Oxygen XML Web Author Component

The *Oxygen SDK* provides the ability to integrate the Oxygen XML Web Author into your existing content ecosystem and it allows anyone in your organization to access your content from anywhere they have an internet connection. Oxygen XML Web Author is highly versatile and can be customized to work with any XML vocabulary, most file repository systems, and virtually any type of workflow.

Web Author Component Integration

For information about integrating Oxygen XML Web Author into your environment, see Web Author Integration.

Web Author Customization

For detailed information about customizing Web Author, see the Oxygen XML Web Author Customization Guide.

Using Web Author

For information about using the Web Author product, see the Oxygen XML Web Author User Manual.

Web Author vs. Web Author Component

The purpose of this topic is to help you choose which distribution of Oxygen XML Web Author is appropriate for your particular use-case.

Oxygen XML Web Author has two distributions:

1. **Oxygen XML Web Author** (product) - This version can be downloaded from the Oxygen website and is licensed according to the Web Author License Agreement.
2. **Web Author Component** - Provided as a Maven artifact (according to the SDK Agreement) that is used in the Web Author Component integration project. This project can be used as a starting point for your integration.

   Note:
   The formal definition for Web Author Component inside the SDK agreement is:
   ""Web Author Component" is a subset of Software composed of a server component operating as a service application and a client component deployed to a web browser, such as an HTML5 based application, where the client component is not installed on the client machine but is in use by the client machine while the browser is connected to the server component."

For End-Users

For end-users, the recommended distribution is **Oxygen XML Web Author** (product).

For Plugin and Framework Developers

If you develop frameworks or plugins that provides enhanced functionality for Oxygen XML Web Author, it is recommended to distribute the plugin or framework separately from Web Author. They will work with both types of distributions and the end-users can choose:

- To install your plugin or framework in Web Author.
- To use a solution based on Web Author that has the plugin or framework installed by default.
- To use a solution based on Web Author and install the plugin or framework themselves.

Example of such plugins/frameworks:

- Integration with a terminology database.
- Adding support to edit embedded SVG snippets.
- Providing support for a specific XML language.

For Integration Developers

If you want to integrate Oxygen XML Web Author into another application (for example, a CMS), that you distribute to your end-users, there are several aspects to consider when choosing between the two distributions:

Functionality

There are some features that are available in the installable **Oxygen XML Web Author** product requires an additional plugin to be available in the **Web Author Component**. For example, the *File Comparison Tool* is available by default in the **Oxygen XML Web Author** product, but requires an additional plugin to be installed for it to be available in the **Web Author Component** version.

Legal

If you want to use the **Web Author Component**, you must have your own application that is not called **Oxygen XML Web Author**, but will contain Web Author as a software component provided by Syncro Soft. Hence, Syncro Soft does not have a direct legal link with your users, you will handle the licensing of your application to your end-users.

For the official details, you can consult the license agreements for both distributions:

1. **Oxygen XML Web Author** (product): https://www.oxygenxml.com/eula_webauthor.html
2. **Web Author Component**: https://www.oxygenxml.com/sdk_agreement.html

Financial

The prices for **Oxygen XML Web Author** (product) are listed on the **Oxygen** website: https://www.oxygenxml.com/xml_web_author/buy_oxygen_xml_web_author.html.

If you choose to use the **Web Author** product to distribute as a plugin or framework, then you act as a channel reseller, basically reselling Oxygen XML Web Author to your end-users and you must pay Syncro Soft the corresponding cost of the license.

The **Web Author Component** has more flexible pricing alternatives for resellers that are negotiated for each contract and include:

- Subscription packages similar to the ones used for the Web Author product, but you may get a discount depending on the partnership level (Gold, Silver, Bronze).
- Solution OEM license.

If you choose to integrate the **Web Author Component** into your application, the cost is based on royalties, rather than a cost for the license. That means you do not need to pay for the ability to include the component in your application, but when you distribute your application you must pay a royalty to Syncro Soft.

Customization

It is strongly recommended to implement any customization as a combination of plugins, frameworks, and options. If you are using **Web Author Component**, you can also alter the Web Author files, but this is discouraged since those files are not considered API and may change in a future version.

Deployment

If you want to use **Oxygen XML Web Author** (product), you can install it using the installation kits, then configure the plugins, frameworks, and options using a browser-based UI. Alternatively, you can configure Oxygen XML Web Author to load the configuration from a custom directory (*Oxygen Data Directory*) along with desired plugins, frameworks, and options.

If you want to use **Web Author Component**, you can use the Web Author Component integration project to build a custom WAR file with plugins, frameworks, and options bundled. This WAR file can be deployed in any Servlet container (for example, Tomcat).

Distribution

If you want to use **Oxygen XML Web Author** (product), your users must download Oxygen XML Web Author from the Oxygen website, while you will distribute your plugins/frameworks to your users. You should provide instructions on how to deploy and use Oxygen XML Web Author. Alternatively, you can install and configure it for them.

If you want to use **Web Author Component**, you will distribute the customized WAR file.

Developer Quick Start Guide

Oxygen XML Editor allows you to develop add-ons to customize the editing experience. Such customizations can be achieved through a plugin or a framework configuration. This section is meant to provide guidance to developers who are getting started with these types of customizations and to offer links to various resources to help with customizations.

- A **plugin** can be used to customize the behavior of the entire application no matter what XML document is currently being edited. Once created, a plugin can be deployed and installed as an add-on *(on page 2565)*. For more information, see the **The Oxygen SDK (Part 1: Plugins)** blog post.
- A **framework** configuration provides validation, content completion, and editing support for a specific XML vocabulary. See: https://blog.oxygenxml.com/topics/oxygenFrameworks.html. Once created, a framework can be deployed and installed as an add-on. See: https://www.oxygenxml.com/doc/ug-editor/topics/packing-and-deploying-addons.html.

From a legal point of view, you can freely develop and share such extensions as long as they are only used from inside Oxygen XML Editor. For details, see: https://www.oxygenxml.com/sdk_agreement.html .

Plugins

A **plugin** can be used to customize the behavior of the entire application no matter what XML document is currently being edited. Since Oxygen XML Editor is a Java-based application, most of the allowed plugin types are Java-based but some JavaScript-based plugin types are also supported.

There are lots of plugin types *(on page 2534)* but the *Workspace Access* plugin type *(on page 2534)* is the most versatile of them. This type of plugin allows you to contribute actions to the main menu and toolbars,

create custom views, interact with the application workspace, make modifications to open documents, and add listeners for various events. A *Workspace Access* plugin can also contribute frameworks *(on page 2542)*.

The Maven-based Oxygen XML SDK comes with sample plugins and it provides the ability to compile Java extensions for your plugins and frameworks. Also, as a quick start for a *Workspace Access* plugin, you can use this project: https://github.com/oxygenxml/sample-plugin-workspace-access.

The *Workspace Access* plugin API can also be used with a JavaScript-based plugin *(on page 2537)*. Small plugin samples can be found here: https://github.com/oxygenxml/wsaccess-javascript-sample-plugins.

You can create automated tests *(on page)* for your plugins and debug them using the Eclipse IDE *(on page 2569)*.

A plugin can either be installed manually or packed as an add-on and installed using **Help->Install new add-ons** *(on page 2533)*.

Sample Plugins

A sample Maven-based Workspace Access plugin can be found here: https://github.com/oxygenxml/sample-plugin-workspace-access.

There is also a sample project which contains various JavaScript-based plugins: https://github.com/oxygenxml/wsaccess-javascript-sample-plugins.

The **Oxygen** GitHub site contains lots of open-source plugins (https://github.com/topics/oxygen-standalone-plugin). Most of these plugins are of the *Workspace Access* type.

You can also find a variety of other publicly-hosted **Oxygen** plugins in the **Public Hosted Oxygen Plugin and Framework Projects** blog post.

Workspace Access Plugin Extension

This type of *plugin* extension allows you to contribute actions to the main menu and toolbars, create custom views, interact with the application workspace, make modifications to open documents, and add listeners for various events. It is the most useful and most commonly used plugin extension.

A *Workspace Access* plugin extension *(on page 2534)* can also provide frameworks, allowing you to have a single add-on that provides both workspace-level extensions (independent of any given framework) and document type-specific frameworks. If the frameworks involve Java extensions (for example, custom dialog boxes or link text resolvers), they use the Java code for the *Workspace Access* plugin.

You can include frameworks with a *Workspace Access* plugin by declaring an "additional frameworks" extension in the **plugin.xml** file *(on page 2542)*.

Java or JavaScript?

Oxygen XML Editor is a Java-based application and all of its APIs are Java-based. The entire user interface (buttons, views, dialog boxes) is built on top of the Java Swing architecture. The entire Javadoc API documentation is available here: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/.

A *Workspace Access* plugin can be implemented either in Java or in JavaScript. Sample Java-based **Workspace Access** plugins can be found on the Oxygen XML GitHub page.

Sample JavaScript-based implementations can be found in this sample project: https://github.com/oxygenxml/wsaccess-javascript-sample-plugins. The Rhino library is used to convert the JavaScript method calls to Java API calls: https://github.com/mozilla/rhino.

Related Information:

- Workspace Access Plugin Extension *(on page 2534)*
- Workspace Access Plugin Extension (JavaScript-Based) *(on page 2537)*

API Overview

The *Workspace Access* plugin extension is called when the application starts and when it closes.

The **StandalonePluginWorkspace** API can be used in numerous ways:

- Customize the toolbars, contextual menu, and main menus. See: Adding Toolbar and Menu Actions *(on page 2587)*.
- Import or set global settings in Oxygen XML Editor. See: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/exml/workspace/api/options/GlobalOptionsStorage.html.
- Access the API for the **Project** view. See: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/exml/workspace/api/standalone/StandalonePluginWorkspace.html#getProjectManager--.
- Access utility methods to interact with the end-user (for example, show warning and error dialog boxes, update the results view, or change the status bar). See: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/exml/workspace/api/WorkspaceUtilities.html.
- Add a listener to be notified when a new XML document is opened, selected, or closed either in the main editing area or in the **DITA Maps Manager** view. See: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/exml/workspace/api/PluginWorkspace.html#addEditorChangeListener-ro.sync.exml.workspace.api.listeners.WSEditorChangeListener-int-.
- Provide access to opened XML documents via the **WSEditor** interface. Each opened XML document can be manipulated using the **WSEditor** interface. You can obtain its content, set new content to it, or save its content. You can also validate the editor contents or disable editing inside it. Depending on the

current editing mode (**Text** or **Author**), you can gain access to the current editing page and send it either to the **Author** editing page or **Text** editing page. Both APIs allow you to make changes to the current document content.

Adding Toolbar and Menu Actions

A *Workspace Access* plugin extension *(on page 2534)* can contribute custom actions to the contextual menu, main menus, or to the general toolbars.

- **Contributing a new toolbar action:**

  This sample Workspace Access plugin contributes a new toolbar called **SampleWorkspaceAccessToolbarID**. The java code of the sample plugin will use the toolbar components customizer API.

- **Contributing an action on the main menu:**

  As exemplified in the sample plugin, the **addMenuBarCustomizer** API can be used either to add a new menu or to customize the existing main menu.

- **Contributing a contextual menu action:**

  The same sample plugin uses the **addMenusAndToolbarsContributorCustomizer** API to contribute a contextual menu customizer. Such a customizer can be contributed either for the **Text** or **Author** editing modes.

Once an action is added, you can define a new shortcut key for it using the **ActionProvider** API. The action can use the **WSEditor API** to make changes to an open XML document.

The same customizer API can be used to remove actions from the main menu, toolbars, framework-specific menus, and contextual menus.

Adding a New Side-View

A *Workspace Access* plugin *(on page 2534)* type can contribute a new side view to Oxygen XML Editor. For example, the following **plugin.xml** descriptor file defines a new view ID called **SampleWorkspaceAccessToolbarID**: https://github.com/oxygenxml/sample-plugin-workspace-access/blob/master/plugin.xml.

Once the new view ID is declared, the Java code of the plugin can add content to the view using the **pluginWorkspaceAccess.addViewComponentCustomizer** API.

Customizing the Project View

The API method StandalonePluginWorkspace.getProjectManager() allows access to various project-related functionalities:

- Add a new contextual menu action in the **Project** view.
- Access the set of resources currently selected in the **Project** view.
- Customize the icons that appear in the **Project** view.

A sample JavaScript-based plugin that uses this API to add a new contextual menu to the **Project** view can be found here: https://github.com/oxygenxml/wsaccess-javascript-sample-plugins/tree/master/OpenInTerminalProjectContextualAction.

Customizing the DITA Maps Manager View

You can add a listener to be notified when a new DITA map is opened, selected, or closed in the **DITA Maps Manager** view. Once the editorOpened() callback is received, you can obtain the opened WSEditor API, then send its current page to the WSDitaMapEditorPage.

The API method WSDitaMapEditorPage allows you to interact with the DITA map that is open in the **DITA maps Manager** view:

- Add a customizer for the icons and text presented in the tree.
- Enable or disable editing on the tree.
- Set a popup menu customizer.
- Get the selected nodes.
- Get access to the AuthorDocumentController API to make changes to the content.

Sample plugins:

- JavaScript-based plugin that customizes the icons and text presented for a DITA map that is open in the **DITA Maps Manager** view: https://github.com/oxygenxml/wsaccess-javascript-sample-plugins/tree/master/dmmCustomizeTopicTitlesAndIcons.
- JavaScript-based plugin that adds a new contextual menu action for a DITA map that is open in the **DITA Maps Manager** view: https://github.com/oxygenxml/wsaccess-javascript-sample-plugins/tree/master/contributePopupActionDMM.

Persistent Storage

Your plugin may need to save plugin-specific information persistently between two sessions. The PluginWorkspace,getOptionsStorage() method allows you to save and retrieve **(key, value)** pairs persistently between sessions (between closing and restarting Oxygen XML Editor). You can also add listeners to be notified when the values for a certain key are changed.

Contributing a Custom Preferences Page

There is a specific plugin extension type that can be used to contribute a custom preferences page *(on page 2548)* to the **Preferences** dialog box in Oxygen XML Editor. An example of how such a page is implemented can be found in this sample plugin: https://github.com/oxygenxml/oxygen-dita-prolog-updater-addon/blob/master/src/main/java/com/oxygenxml/prolog/updater/plugin/PrologOptionPageExtension.java.

Imposing a Fixed Set of Global Preferences

You may want to impose a fixed set of global options to be used by all end-users who install the plugin. The GlobalOptionsStorage API provides the ability to set the following:

- **Set a certain global option to a certain value:** (https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/exml/workspace/api/options/GlobalOptionsStorage.html#setGlobalObjectProperty-java.lang.String-java.lang.Object-) The APIAccessibleOptionTags interface contains a list with all keys that can be set to a custom value.
- **Set global options by importing an options XML file:** (https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/exml/workspace/api/options/GlobalOptionsStorage.html#importGlobalOptions-java.io.File-) Such an options XML file can be generated by using the **Options->Export Global Options** action in Oxygen XML Editor. A sample JavaScript-based *WorkspaceAccess* plugin implementation that imports such an options XML document into the application can be found here: https://github.com/oxygenxml/wsaccess-javascript-sample-plugins/tree/master/impose-options.

Other ways to share a common set of options with others are listed here: https://blog.oxygenxml.com/topics/sharingSettings.html.

Interaction with the End-User

If you need your plugin to frequently interact with the end user, some possibilities include:

- Your plugin can create Java Swing-based components (dialog boxes, frames) that are displayed when custom toolbar or menu actions *(on page 2587)* added by the plugin are called. You can also extend the **Oxygen**-specific API base class *OKCancelDialog* to create a dialog box that already includes **OK** and **Cancel** buttons. This specific base also automatically resizes its internal components depending on the currently used fonts or DPI settings and also properly positions the **OK** and **Cancel** buttons depending on the operating system (on macOS, the **OK** button is on the right part of the dialog box, while on Windows and Linux, it is placed on the left part of the dialog box). There is an entire API package that contains base implementations of Swing components and such implementations are recommended to be used for the plugin-contributed components to look like the ones contributed by Oxygen XML Editor.
- Your plugin can add a specific side view *(on page 2587)*.
- The *WorkspaceUtilities* API allows you to:

    - Show file and folder choosers.
    - Show confirmation dialog boxes.
    - Show information, warning, or error dialog boxes.
    - Show a custom status message in the application.

- The *ResultsManager* API allows you to add results in the **Results** view. These results can point to a specific document at a specific line/column location.
- The title of the main application frame can be modified using this API: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/exml/workspace/api/Workspace.html#setParentFrameTitle-java.lang.String-.

Contributing Translations for New Labels and UI Text

You may want your plugin's interaction with the end-user (dialog boxes, pop-up messages, etc.) to be properly translated in all user interface languages *(on page 347)* supported by Oxygen XML Editor. The API method *StandalonePluginWorkspace.getResourceBundle()* will allow you to pass message keys that will be resolved by the application to specific language-dependent values by looking at a file called **translation.xml**, which needs to be placed in a folder called **i18n** in the plugin installation folder. The structure of the **translation.xml** file needs to look like this: https://www.oxygenxml.com/doc/ug-editor/topics/contribute-new-languages-extension.html.

Comparing Documents

Using a Workspace Access plugin extension, you have access to various APIs that allow the comparison of XML documents:

- Display the **Compare Files** tool with a given set of URLs for two-way or three-way comparisons: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/exml/workspace/api/standalone/DiffAndMergeTools.html.
- Compare documents in-memory (for example, to generate reports): https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/exml/workspace/api/util/CompareUtilAccess.html.

Customizing the Application Layout

There are two main ways to customize the layout of the application:

- Remove some of the toolbars, actions, menus, or views that Oxygen XML Editor shows by default when the application starts. A sample plugin that filters the user interface based on an XML configuration file is available here: https://github.com/oxygenxml/oxygen-components-filter-plugin.
- Export the layout of the current views and toolbars in the application using the **Window->Export Layout** action, then use the *WorkspaceAccess* plugin API to impose a fixed value for a global option key:

```
File layoutFile = new File(baseDir, "application.layout");
if (layoutFile.exists()) {
    PerspectivesLayoutInfo info = new PerspectivesLayoutInfo(true, false, "",
 layoutFile.getAbsolutePath());
    pluginWorkspaceAccess.setGlobalObjectProperty("perspectives.layout.info", info);
...
```

Adding new User Interface Translations

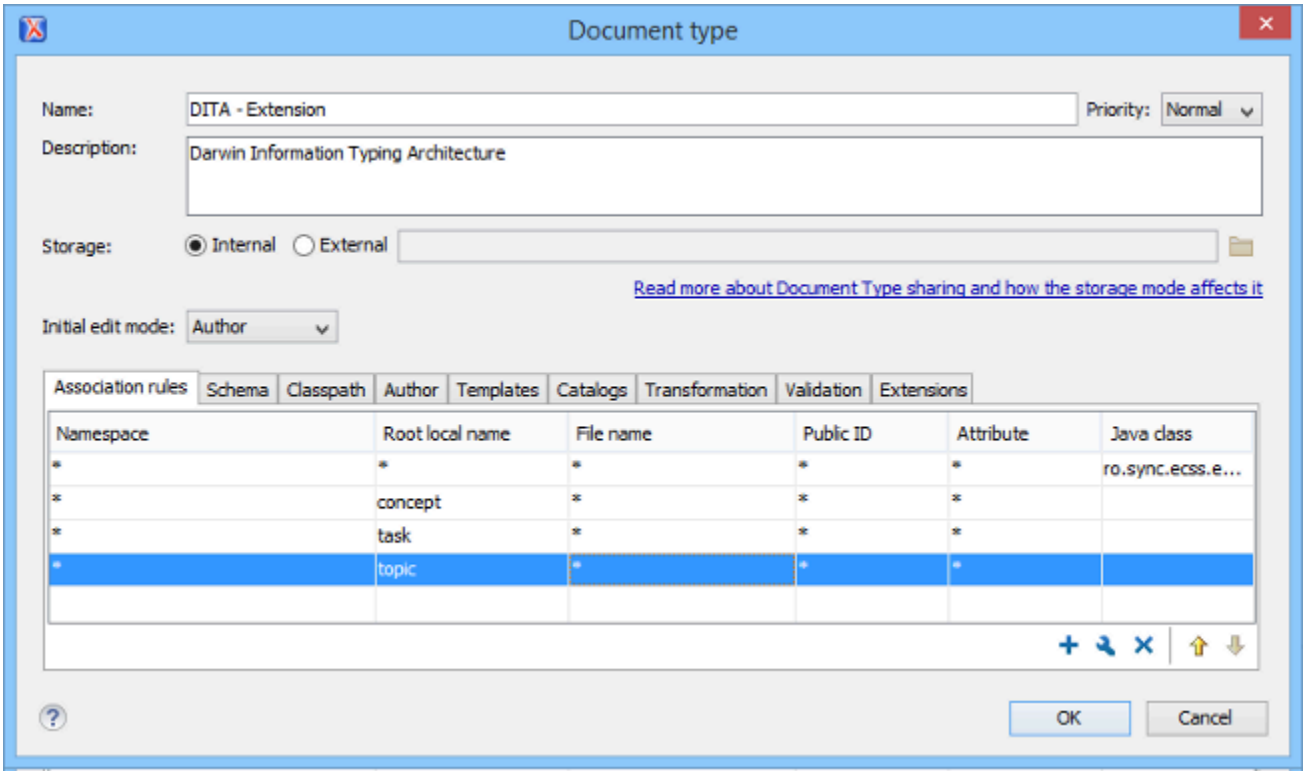
There is a particular plugin extension to contribute a new language to Oxygen XML Editor: https://www.oxygenxml.com/doc/ug-editor/topics/contribute-new-languages-extension.html.

Frameworks

A *framework* configuration provides validation, content completion, and visual editing functionality for a certain XML vocabulary. Usually, a framework customization provides a schema used to validate and edit certain type of XML documents, a CSS used to edit the XML documents in the **Author** visual editing mode and various custom actions or behaviors used to enhance the editing experience. For more information about framework customization, see: https://blog.oxygenxml.com/topics/oxygenFrameworks.html.

Oxygen XML Editor comes with a lot of framework configuration folders (**[OXYGEN_INSTALL_DIR]/frameworks**) to support editing XML documents of various types (such as DocBook, DITA, XHTML, or TEI). All of these existing framework configurations can be further customized in the **Preferences->Document Type Associations** page. These framework configurations can be used as examples for building your own customization for a certain XML vocabulary or they can be extended if you want to share a modified version of a framework with others.

The **Document Type Association** configuration dialog box allows you to configure all the framework-specific settings.



You can also find various open-source frameworks for Oxygen XML Editor online: https://blog.oxygenxml.com/topics/Oxygen%20plugins%20and%20frameworks.html.

Once you have set up a framework configuration folder, it can be packaged as an add-on and shared with others or it can be packaged in *workspace access* plugins using the "additional framework" extension point in the **plugin.xml** file *(on page 2542)*.

Customizing an Existing Framework

An existing framework that has full built-in support (for example the **DITA** framework) can be extended and customized. Afterward, this customization can be shared with others. You can use such a framework customization extension to:

- Provide custom new file templates.
- Provide a custom CSS layer to render the framework in the **Author** visual editing mode.
- Provide custom Schematron-based validation for the XML documents.
- Provide custom Author mode actions on the toolbar, in the contextual menu, and in the main framework-specific menu.

Customizing the Content Completion Proposals

When editing an XML document either in the **Text** or **Author** editing modes, you can invoke the **Content Completion Assistant** (**Ctrl+Space** in **Text** mode or **ENTER** in **Author** mode) to see the allowed XML elements or attributes that can be inserted at the current location. The **Elements** view also presents the elements that

can be inserted in the document at a certain location, while the **Attributes** view presents a list of allowed attributes and their values.

The content completion proposals can be customized in various ways:

- Each framework can contain a special content completion configuration file. Such a file can:
  - Filter out element proposals for a parent element.
  - Configure a set of required attributes to be inserted along with a certain element.
  - Add new attribute value proposals and for each proposal, add an annotation that will appear in the **Attributes** view for each value.
  - Call an external XSLT script to compute value proposals for a certain attribute.
  - Customize how the element names are presented in the **Outline** view, **Elements** view, and **Content Completion Assistant**.
- You can alter the schema that is associated with the XML document. For example, in the case of the **DITA** vocabulary, you can create a DTD specialization plugin and integrate it into Oxygen XML Editor.
- You can use the **SchemaManagerFilter** API to filter the set of proposed elements and attribute values using Java code.

Adding Custom New File Templates

The New Document Wizard *(on page 377)* (**File->New** or the **New** button on the toolbar) presents custom file templates gathered from all frameworks installed in Oxygen XML Editor. A custom framework can have one or more special folders that contain custom new file templates.

Adding Custom Validation Stages

You can distribute a framework with a series of already configured validation scenarios. Also, this provides enhanced validation support that allows you to use multiple grammars to check the document. For example, you can use Schematron rules to impose guidelines that are otherwise impossible to enforce using conventional validation. See: Configuring Validation Scenarios for a Framework.

Adding Custom Transformation Scenarios

When distributing a framework to users, it is a good idea to have the transformation scenarios already configured. This helps the content authors publish their work in various formats. By being contained in the framework configuration, the scenarios can be distributed along with the actions, menus, toolbars, and catalogs. See: Configuring Transformation Scenarios for a Framework.

Customizing the Author Visual Editing Mode

The **Author** visual editing mode is based on CSS. Besides supporting most of the CSS 3 specification, Oxygen XML Editor adds some custom CSS selectors, properties, and functions. Customization possibilities include:

- Use CSS selectors to match XML comments, processing instructions, entities, and CDATA sections.
- Change the tags display mode and tag color for certain elements, mark certain XML elements as not editable, and other customizations using additional CSS properties.
- Use custom CSS functions. For example, the **oxy_xpath** function allows you to run an XPath search over the document and use that value as static text.
- In custom pseudo-classes, you can match values that can be changed via a custom action.
- There are specific @media types that can be used to mark certain CSS sections for a certain distribution.
- Fonts can be dynamically loaded and used for rendering.

Adding Toolbar and Menu Actions

The framework customization *(on page 2591)* can define actions that appear on a framework-specific toolbar when editing content in the **Author** visual editing mode.

You can use the **Author Action** dialog box *(on page 155)* to configure the name, description, icons, menu shortcuts, and various XPath-enabled activation operations *(on page 159)*.

You can use a variety of pre-defined operations in each activation mode to achieve various things:

- Insert an XML fragment in the document either at the current position or at a specified offset.
- Set an attribute with a certain value on a certain element.
- Invoke an XSLT script using the **XSLTOperation** to produce an XML fragment to be inserted in the document.
- Invoke a JavaScript function that can use the **Author** mode APIs to modify the document. Some samples of such operations can be found here: https://github.com/oxygenxml/javascript-sample-operations.
- Set a CSS pseudo-class on a certain element. The pseudo-class can be matched from the CSS to style various elements differently.

You can also create custom **Author** mode operations by extending the **AuthorOperation** Java API.

Once a custom action has been created, it can be added to the main menu, toolbar, or contextual menu.

Embedding Form Controls

By using custom CSS functions, you can embed form controls (checkboxes, combo boxes, text fields, pop-up boxes, buttons, etc.) in the **Author** visual editing mode to edit attribute values or text content for certain elements.

All the supported form controls can be found in the Form Controls section.

Sample XML and CSS documents that use form controls can be found in the **[OXYGEN_INSTALL_DIR]/samples/form-controls** folder.

Adding Inline Actions

Using the oxy_button and oxy_buttonGroup form controls, you can add inline actions in the **Author** visual editing mode. To see an example, you can open a Lightweight DITA topic from the folder **[OXYGEN_INSTALL_DIR]/samples/dita/lw-dita/**.

Debugging CSS-related Problems

The **CSS Inspector** view can be used to find out how various CSS styles are applied. For more information, see Debugging CSS Stylesheets.

Customizing Links

If you need to have working links between your XML document instances in the **Author** visual editing mode, consider the following possibilities:

- You can use the *-oxy-link* CSS property to specify a link target on a static icon placed before the element.
- You can use the *oxy_link-text()* CSS function to take control over the text presented inside a link using a specific Java extension.
- You can use a custom **ExtensionsBundle** implementation to be notified on a specific callback if the reference needs further processing.
- You can implement a custom link target element finder if the links are not referenced directly to elements that have an ID attribute. The link target element finder will be used to locate the target when the end-user clicks the link.

Related information

Sample DITA (framework) extension that sets a custom `ExtensionsBundle` implementation for customizing links

Customizing the Smart Paste Mapping

The *Smart Paste* feature in Oxygen XML Editor preserves certain style and structure information when copying content and pasting it into XML documents. It is also possible to customize the mapping for the *Smart Paste* mechanism.

If you want full control over this behavior, there are also Java extensions that can be customized.

Difference Between a Framework (Document Type) and a Plugin Extension

Question

What is the difference between a *Framework (on page 3420)* and a *Plugin (on page 3422)* Extension?

Answer

There are two possible ways to customize the application:

1. Implement a *plugin*.

   A *plugin* serves a general purpose and influences any type of XML file that you open in Oxygen XML Editor.

   For the Oxygen XML Editor Plugins API, Javadoc, samples, and documentation, go to https://www.oxygenxml.com/oxygen_sdk.html#Developer_Plugins

2. Create or modify the document type *(on page 2248)* that is associated to your specific XML vocabulary.

   This document type can be used, for instance, to provide custom actions for your type of XML files and to mount them on the toolbar, menus, and contextual menus.

   For example, if the end-users are editing DITA documents, all the toolbar actions that are specific for DITA are provided by the DITA *framework*. If you look in the **Document Type Association** preferences page *(on page 145)* there is a *DITA* document type. If you edit that document type you will see that it has an **Author** tab in the **Document Type Configuration** dialog box *(on page 147)*. The subtabs in this tab can be used to define custom DITA actions and add them to the toolbars, main menus, or contextual menus.

   For information about developing your own document types (*frameworks*), see the Creating and Configuring Custom Frameworks *(on page 2248)* section.

   If you look on disk in the `[OXYGEN_INSTALL_DIR]\frameworks\dita` folder, there is a file called `dita.framework`. That file gets updated when you edit a document type from the **Document Type Association** preferences page *(on page 145)*. Then you can share that updated file with all users.

   The same folder contains some *JAR (on page 3420)* libraries. These libraries contain custom Java operations that are called when the user presses certain toolbar actions.

The *Oxygen SDK* contains the Java sources from all the DITA Java customizations:

https://www.oxygenxml.com/oxygen_sdk.html#XML_Editor_Authoring_SDK

Important:
It is possible for a *plugin* to share the same classes with a *framework*. For further details, go to How to Share the Classloader Between a Framework and a Plugin *(on page 2564)*.

Related Information:
Adding a Custom Operation to an Existing Framework *(on page 2295)*

SDK Common Use Cases

This section contains details for specific use cases regarding customizations using the *Oxygen SDK*, Author Component *(on page 2571)*, or plugins *(on page 2530)*.

For additional questions, contact the *Oxygen support team*. The preferred approach is via email because these types of questions must be analyzed thoroughly. The *Oxygen support team* also provides code snippets, if applicable.

To stay up-to-date with the latest changes, discuss issues, and ask for solutions from other developers working with the *Oxygen SDK*, register on the Oxygen-SDK mailing list.

Add Custom Actions to the Contextual Menu

Use Case

You want to add your own custom actions to the contextual menu using an API.

Solution

The *WSAuthorEditorPageBase.addPopUpMenuCustomizer* and *WSTextEditorPage.addPopUpMenuCustomizer* API methods allow you to customize the contextual menu shown either in the **Author** or **Text** modes. The API is available both in the standalone application and in the Eclipse plugin.

To add actions to the **Author** page from your Eclipse plugin extension:

1. Create a pop-up menu customizer implementation:

```
import org.eclipse.jface.action.ContributionManager;
import org.eclipse.ui.PlatformUI;
import org.eclipse.ui.menus.IMenuService;
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.structure.AuthorPopupMenuCustomizer;
```

```
/**
* This class is used to create the possibility to attach certain
* menuContributions to the {@link ContributionManager}, which is used for the
* popup menu in the Author Page of the Oxygen Editor.<br />
* You just need to use the org.eclipse.ui.menus extension and add a
* menuContribution with the locationURI: <b>menu:oxygen.authorpage</b>
*/
public class OxygenAuthorPagePopupMenuCustomizer implements
        AuthorPopupMenuCustomizer {

    @Override
    public void customizePopUpMenu(Object menuManagerObj,
            AuthorAccess authoraccess) {
        if (menuManagerObj instanceof ContributionManager) {
 ContributionManager contributionManager = (ContributionManager) menuManagerObj;
            IMenuService menuService = (IMenuService) PlatformUI.getWorkbench()
                    .getActiveWorkbenchWindow().getService(IMenuService.class);

            menuService.populateContributionManager(contributionManager,
                    "menu:oxygen.authorpage");
            contributionManager.update(true);
        }
    }
}
```

2. Add a workbench listener and add the pop-up customizer when an editor is open in the **Author** page:

```
Workbench.getInstance().getActiveWorkbenchWindow().getPartService()
.addPartListener(
    new IPartListener() {
      @Override
      public void partOpened(IWorkbenchPart part) {
        if(part instanceof ro.sync.exml.workspace.api.editor.WSEditor) {
          WSEditorPage currentPage = ((WSEditor)part).getCurrentPage();
          if(currentPage instanceof WSAuthorEditorPage) {
            ((WSAuthorEditorPage)currentPage).addPopUpMenuCustomizer
(new OxygenAuthorPagePopupMenuCustomizer());
          }
        }
      }
      ........
    });
```

3. Implement the extension point in your `plugin.xml` file:

```
<extension
       point="org.eclipse.ui.menus">
    <menuContribution
          allPopups="false"
          locationURI="menu:oxygen.authorpage">
       <command
             commandId="eu.doccenter.kgu.client.tagging.removeTaggingFromOxygen"
             style="push">
       </command>
    </menuContribution>
</extension>
```

Add Custom Callouts

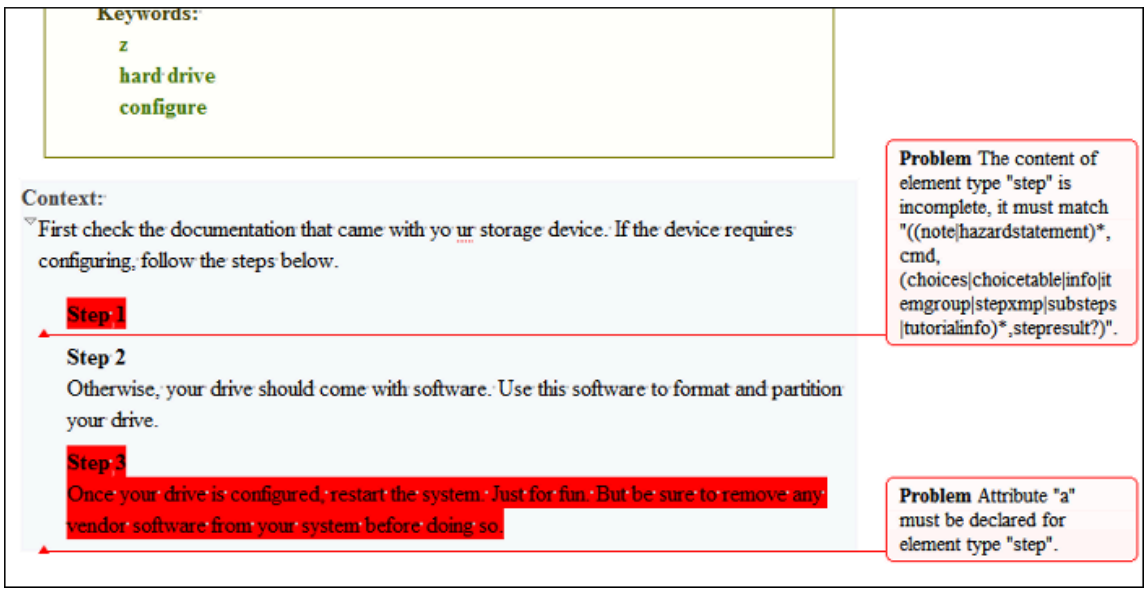
Use Case

You want to highlight validation errors, instead of underlining them (for example, changing the text background color to red or yellow) and display a message directly at the error position that describes the problem.

Solution

The Plugins API allows you to set a *ValidationProblemsFilter* that gets notified when automatic validation errors are available. Then you can map each of the problems to an offset range in the **Author** mode using the API *WSTextBasedEditorPage.getStartEndOffsets(DocumentPositionedInfo)*. For each of those offsets, you can add either persistent or non-persistent highlights. If you add persistent highlights, you can also customize callouts to appear for each of them. The downside is that they need to be removed before the document gets saved. The result would look something like this:

Figure 623. Custom Callouts with Persistent Highlights



Here is a working example:

```
/**
* Plugin extension - workspace access extension.
*/
public class CustomWorkspaceAccessPluginExtension
                    implements WorkspaceAccessPluginExtension {

/**
* @see ro.sync.exml.plugin.workspace.WorkspaceAccessPluginExtension
   #applicationStarted(
ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace)
*/
    public void applicationStarted
(final StandalonePluginWorkspace pluginWorkspaceAccess) {
        pluginWorkspaceAccess.addEditorChangeListener
(new WSEditorChangeListener() {
          /**
           * @see WSEditorChangeListener#editorOpened(java.net.URL)
           */
          @Override
          public void editorOpened(URL editorLocation) {
            final WSEditor currentEditor = pluginWorkspaceAccess.getEditorAccess
(editorLocation, StandalonePluginWorkspace.MAIN_EDITING_AREA);
            WSEditorPage currentPage = currentEditor.getCurrentPage();
            if(currentPage instanceof WSAuthorEditorPage) {
              final WSAuthorEditorPage currentAuthorPage =
(WSAuthorEditorPage)currentPage;
              currentAuthorPage.getPersistentHighlighter().setHighlightRenderer
(new PersistentHighlightRenderer() {
                @Override
                public String getTooltip(AuthorPersistentHighlight highlight) {
                  return highlight.getClonedProperties().get("message");
                }
                @Override
                public HighlightPainter getHighlightPainter
(AuthorPersistentHighlight highlight) {
                  //Depending on severity could have different color.
                  ColorHighlightPainter painter = new ColorHighlightPainter
(Color.COLOR_RED, -1, -1);
                  painter.setBgColor(Color.COLOR_RED);
                  return painter;
                }
```

```
            });
        currentAuthorPage.getReviewController()
        .getAuthorCalloutsController().setCalloutsRenderingInformationProvider(
              new CalloutsRenderingInformationProvider() {
              @Override
    public boolean shouldRenderAsCallout(AuthorPersistentHighlight highlight) {
                //All custom highlights are ours
                return true;
              }
              @Override
    public AuthorCalloutRenderingInformation getCalloutRenderingInformation(
                  final AuthorPersistentHighlight highlight) {
                return new AuthorCalloutRenderingInformation() {
                  @Override
                  public long getTimestamp() {
                    //Not interesting
                    return -1;
                  }
                  @Override
                  public String getContentFromTarget(int limit) {
                    return "";
                  }
                  @Override
                  public String getComment(int limit) {
                    return highlight.getClonedProperties().get("message");
                  }
                  @Override
                  public Color getColor() {
                    return Color.COLOR_RED;
                  }
                  @Override
                  public String getCalloutType() {
                    return "Problem";
                  }
                  @Override
                  public String getAuthor() {
                    return "";
                  }
                  @Override
                  public Map<String, String> getAdditionalData() {
                    return null;
                  }
```

```
                };
              }
            });
 currentEditor.addValidationProblemsFilter(new ValidationProblemsFilter() {
    List<int[]> lastStartEndOffsets = new ArrayList<int[]>();
    /**
    * @see ro.sync.exml.workspace.api.editor.validation.ValidationProblemsFilter
    #filterValidationProblems
(ro.sync.exml.workspace.api.editor.validation.ValidationProblems)
     */
   @Override
   public void filterValidationProblems(ValidationProblems validationProblems) {
     List<int[]> startEndOffsets = new ArrayList<int[]>();
     List<DocumentPositionedInfo> problemsList =
validationProblems.getProblemsList();
     if(problemsList != null) {
       for (int i = 0; i < problemsList.size(); i++) {
         try {
 startEndOffsets.add(currentAuthorPage.getStartEndOffsets(problemsList.get(i)));
         } catch (BadLocationException e) {
           e.printStackTrace();
         }
       }
     }
       if(lastStartEndOffsets.size() != startEndOffsets.size()) {
         //Continue
       } else {
         boolean equal = true;
         for (int i = 0; i < startEndOffsets.size(); i++) {
           int[] o1 = startEndOffsets.get(i);
           int[] o2 = lastStartEndOffsets.get(i);
           if(o1 == null && o2 == null) {
             //Continue
           } else  if(o1 != null && o2 != null
               && o1[0] == o2[0] && o1[1] == o2[1]){
             //Continue
           } else {
             equal = false;
             break;
           }
         }
         if(equal) {
```

```
            //Same list of problems already displayed.
            return;
          }
        }
        //Keep last used offsets.
        lastStartEndOffsets = startEndOffsets;
      try {
        if(! SwingUtilities.isEventDispatchThread()) {
          SwingUtilities.invokeAndWait(new Runnable() {
            @Override
          public void run() {
              //First remove all custom highlights.
      currentAuthorPage.getPersistentHighlighter().removeAllHighlights();
            }
          });
      }
      } catch (InterruptedException e1) {
      e1.printStackTrace();
      } catch (InvocationTargetException e1) {
        e1.printStackTrace();
      }
      if(problemsList != null) {
        for (int i = 0; i < problemsList.size(); i++) {
          //A reported problem (could be warning, could be error).
          DocumentPositionedInfo dpi = problemsList.get(i);
          try {
            final int[] currentOffsets = startEndOffsets.get(i);
            if(currentOffsets != null) {
              //These are offsets in the Author content.
              final LinkedHashMap<String, String> highlightProps =
new LinkedHashMap<String, String>();
              highlightProps.put("message", dpi.getMessage());
              highlightProps.put("severity", dpi.getSeverityAsString());
              if(! SwingUtilities.isEventDispatchThread()) {
                SwingUtilities.invokeAndWait(new Runnable() {
                  @Override
                  public void run() {
                   currentAuthorPage.getPersistentHighlighter().addHighlight(
                    currentOffsets[0], currentOffsets[1] - 1, highlightProps);
             }
                });
              }
```

```
          }
        } catch (InterruptedException e) {
          e.printStackTrace();
        } catch (InvocationTargetException e) {
          e.printStackTrace();
        }
      }
     }
    }
});
 currentEditor.addEditorListener(new WSEditorListener() {
  /**
  * @see WSEditorListener#editorAboutToBeSavedVeto(int)
  */
  @Override
  public boolean editorAboutToBeSavedVeto(int operationType) {
      try {
       if(! SwingUtilities.isEventDispatchThread()) {
        SwingUtilities.invokeAndWait(new Runnable() {
          @Override
          public void run() {
            //Remove all persistent highlights before saving
             currentAuthorPage.getPersistentHighlighter().removeAllHighlights();
           }
        });
       }
     } catch (InterruptedException e) {
     e.printStackTrace();
    } catch (InvocationTargetException e) {
       e.printStackTrace();
    }
    return true;
    }
   });
  }
 }
}, StandalonePluginWorkspace.MAIN_EDITING_AREA);
      }

/**
* @see WorkspaceAccessPluginExtension#applicationClosing()
```

```
     */
    public boolean applicationClosing() {
      return true;
    }
  }
```

Add Custom Highlights to Content

Use Case

You want to add custom highlights to the document content in **Author** mode.

Solution

There are two types of highlights you can add:

1. **Non-Persistent Highlights** - Such highlights are removed when the document is closed and then re-opened.

   You can use the following API method:

   `ro.sync.exml.workspace.api.editor.page.author.WSAuthorEditorPageBase.getHighlighter()`

   to obtain an AuthorHighlighter that allows you to add a highlight between certain offsets with a specified painter.

   For example, you can use this support to implement your own spell checker with a custom highlight for the unrecognized words.

2. **Persistent Highlights** - Such highlights are saved in the XML content as processing instructions.

   You can use the following API method:

   `ro.sync.exml.workspace.api.editor.page.author.WSAuthorEditorPageBase.getPersistentHighlighter()`

   to obtain an AuthorPersistentHighlighter class that allows you to add a persistent highlight between certain offsets, set new properties for a specific highlight, and render it with a specified painter.

   For example, you can use this support to implement your own way of adding review comments.

Adding Custom Persistent Highlights *(on page 2356)*

Auto-Generate an ID When a Document is Opened or Created

Use Case

You want to configure how the application generates IDs (you need IDs that have a certain format for each created topic).

Solution

This could be done implementing a *plugin (on page 3422)* for Oxygen XML Editor using the Plugins SDK:

There is a type of *plugin* called "Workspace Access" that can be used to add a listener to be notified when an editor is opened.

The implemented *plugin* would intercept the open editor and editor page change events (which occur when a new editor is created) and generate a new ID attribute value on the root element.

The Java code would look like this:

```
pluginWorkspaceAccess.addEditorChangeListener(new WSEditorChangeListener() {
/**
* @see WSEditorChangeListener#editorOpened(java.net.URL)
*/
@Override
public void editorOpened(URL editorLocation) {
    WSEditor ed = pluginWorkspaceAccess.getEditorAccess
(editorLocation, PluginWorkspace.MAIN_EDITING_AREA);
        generateID(ed);
}
/**
* @see WSEditorChangeListener#editorPageChanged(java.net.URL)
*/
@Override
public void editorPageChanged(URL editorLocation) {
    WSEditor ed = pluginWorkspaceAccess.getEditorAccess
(editorLocation, PluginWorkspace.MAIN_EDITING_AREA);
        generateID(ed);
}

private void generateID(WSEditor ed) {
 if(ed.getCurrentPage() instanceof WSAuthorEditorPage) {
  WSAuthorEditorPage authorEditPage = (WSAuthorEditorPage) ed.getCurrentPage();
  AuthorDocumentController ctrl = authorEditPage.getDocumentController();
  AuthorElement root = ctrl.getAuthorDocumentNode().getRootElement();
   if(root.getAttribute("id") == null ||
!root.getAttribute("id").getValue().startsWith("generated_")) {
```

```
    ctrl.setAttribute("id", new AttrValue("generated_" + Math.random()), root);
          }
        }
      }

    }, PluginWorkspace.MAIN_EDITING_AREA);
```

Change the Default Track Changes (Review) Author Name

Use Case

You want to change the default author name used for *Tracked Changes (on page 3424)* in the *Author Component*.

Solution

The *Track Changes* (Review) author name is determined in the following order:

1. **API** - The review user name can be imposed through the following API:

   ```
   ro.sync.ecss.extensions.api.AuthorReviewController.setReviewerAuthorName(String)
   ```

2. **Options** - If the author name was not imposed from the API, it is determined from the **Author** option set in the **Review** preferences page *(on page 191)*.
3. **System properties** - If the author name was not imposed from the API or from the application options then the following system property is used:

   ```
   System.getProperty("user.name")
   ```

So, to impose the *Track Changes* author, use one of the following approaches:

1. Use the API to impose the reviewer author name. Here is the online Javadoc of this method: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/AuthorReviewController.html#setReviewerAuthorName(java.lang.String)
2. Customize the default options and set a specific value for the **Author** name option set in the **Review** preferences page *(on page 191)*.
3. Set the value of `user.name` system property when the *Author Component* is initializing and before any document is loaded.

Change the DOCTYPE of an Open XML Document

Use Case

You want to change the DOCTYPE of a document that is open in the **Author** mode.

Solution

The following API:

`ro.sync.ecss.extensions.api.AuthorDocumentController.getDoctype()`

allows you to get the `DOCTYPE` of the current XML file open in the **Author** mode.

There is also an API method available that would allow you to set the `DOCTYPE` back to the XML:

`ro.sync.ecss.extensions.api.AuthorDocumentController.setDoctype(AuthorDocumentType)`

Here is an example of how this solution would work:

```
AuthorDocumentType
dt = new AuthorDocumentType("article", "testSystemID", "testPublicID",
     "<!DOCTYPE article PUBLIC \"testPublicID\" \"testSystemID\">");
docController.setDoctype(dt);
```

Basically, you could take the entire content from the existing DOCTYPE,

`ro.sync.ecss.extensions.api.AuthorDocumentType.getContent()`

modify it to your needs, and create another `AuthorDocumentType` object with the new content and with the same public, system IDs.

For example, you could use this API is you want to add unparsed entities in the XML `DOCTYPE`.

Control XML Serialization in the Oxygen XML Author Component

Use Case

You want to force the Oxygen XML Author Component to save the XML with zero indent size and not to break the line inside *block elements (on page 3417)*.

Solution

Usually, in a standalone version of Oxygen XML Editor, the **Editor > Format** and **Editor > Format > XML** preferences pages allow you to control the way the XML is saved on the disk after you edit it in the **Author** mode.

Also, the *APIAccessibleOptionTags* interface contains a list of all accessible keys that can be read or set from the options.

In the Oxygen XML Editor application, you can either bundle a default set of options *(on page 318)* or use the `PluginWorkspace.setGlobalObjectProperty(String, Object)` API:

```
//For not breaking the line
//Long line
pluginWorkspace.setObjectProperty
  (APIAccessibleOptionTags.EDITOR_LINE_WIDTH, new Integer(100000));
//Do not break before inline elements
pluginWorkspace.setObjectProperty
```

```
  (APIAccessibleOptionTags.EDITOR_FORMAT_INDENT_INLINE_ELEMENTS, false);
//For forcing zero indent
//Force indent settings to be controlled by us
pluginWorkspace.setObjectProperty
  (APIAccessibleOptionTags.EDITOR_DETECT_INDENT_ON_OPEN, false);
//Zero indent size
pluginWorkspace.setObjectProperty
  (APIAccessibleOptionTags.EDITOR_INDENT_SIZE, 0);
```

In the Oxygen XML Author Component, you can either bundle a fixed set of options *(on page 2621)*, or use the *Java API* to set properties that overwrite the default options.

```
    //For not breaking the line
    //Long line
    AuthorComponentFactory.getInstance().setObjectProperty
(APIAccessibleOptionTags.EDITOR_LINE_WIDTH, new Integer(100000));
    //Do not break before inline elements
    AuthorComponentFactory.getInstance().setObjectProperty
(APIAccessibleOptionTags.EDITOR_FORMAT_INDENT_INLINE_ELEMENTS, false);
    //For forcing zero indent
    //Force indent settings to be controlled by us
    AuthorComponentFactory.getInstance().setObjectProperty
(APIAccessibleOptionTags.EDITOR_DETECT_INDENT_ON_OPEN, false);
    //Zero indent size
    AuthorComponentFactory.getInstance().setObjectProperty
(APIAccessibleOptionTags.EDITOR_INDENT_SIZE, 0);
```

API Interface Documentation: *APIAccessibleOptionTags*

Customize the Outline View in Text Mode

Use Case

You want to customize the **Outline** view *(on page 549)* in **Text** mode.

Solution

Suppose that you have the following XML document:

```
<doc startnumber="15">
    <sec counter="no">
        <info/>
        <title>Introduction</title>
      </sec>
```

```
    <sec>
        <title>Section title</title>
      <para>Content</para>
        <sec>
            <title>Section title</title>
                <para>Content</para>
        </sec>
    </sec>
    <sec>
            <title>Section title</title>
        <para>Content</para>
      </sec>
</doc>
```

and you want to display the XML content in a simplified Outline view like this:

```
doc "15"
sec Introduction
sec 15 Section title
sec 15.1 Section title
sec 16 Section title
```

Usually, an Outline view should have the following characteristics:

1. Double-clicking a node in the Outline view would select the corresponding XML content in the editor.
2. When the cursor moves in the open XML document, the Outline view would select the proper entry.
3. When modifications occur in the document, the Outline view would refresh.

A simple implementation using a Workspace Access plugin type could be something like this:

```
/**
 * Simple Outline for Text mode based on executing XPaths over the text content.
 */
 public class CustomWorkspaceAccessPluginExtension implements
WorkspaceAccessPluginExtension {
  /**
   * The custom outline list.
   */
  private JList customOutlineList;

  /**
   * Maps outline nodes to ranges in document
   */
  private WSXMLTextNodeRange[] currentOutlineRanges;
```

```
  /**
   * The current text page
   */
  private WSXMLTextEditorPage currentTextPage;

  /**
   * Disable CaretListener when we select from the CaretListener.
   */
  private boolean enableCaretListener = true;

  /**
   * @see WorkspaceAccessPluginExtension#applicationStarted
(ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace)
   */
  @Override
  public void applicationStarted
(final StandalonePluginWorkspace pluginWorkspaceAccess) {
    pluginWorkspaceAccess.addViewComponentCustomizer
(new ViewComponentCustomizer() {
      /**
       * @see ViewComponentCustomizer#customizeView
(ro.sync.exml.workspace.api.standalone.ViewInfo)
       */
      @Override
      public void customizeView(ViewInfo viewInfo) {
        if(
            //The view ID defined in the "plugin.xml"
            "SampleWorkspaceAccessID".equals(viewInfo.getViewID())) {
          customOutlineList = new JList();
          //Render the content in the Outline.
          customOutlineList.setCellRenderer(new DefaultListCellRenderer() {
       /**
        * @see javax.swing.DefaultListCellRenderer#getListCellRendererComponent
(javax.swing.JList, java.lang.Object, int, boolean, boolean)
        */
      @Override
      public Component getListCellRendererComponent
(JList<?> list, Object value, int index,
          boolean isSelected, boolean cellHasFocus) {
        JLabel label = (JLabel) super.getListCellRendererComponent
(list, value, index, isSelected, cellHasFocus);
        String val = null;
```

```
        if(value instanceof Element) {
          Element element = ((Element)value);
          val = element.getNodeName();
          if(!"".equals(element.getAttribute("startnumber"))) {
            val += " " + "'" + element.getAttribute("startnumber") + "'";
          }
          NodeList titles = element.getElementsByTagName("title");
          if(titles.getLength() > 0) {
            val += " \"" + titles.item(0).getTextContent() + "\"";
         }
       }
        label.setText(val);
        return label;
      }
    });
    //When we click a node, select it in the text page.
    customOutlineList.addMouseListener(new MouseAdapter() {
     @Override
     public void mouseClicked(MouseEvent e) {
       if(SwingUtilities.isLeftMouseButton(e) && e.getClickCount() == 2) {
          int sel = customOutlineList.getSelectedIndex();
          enableCaretListener = false;
         try {
          currentTextPage.select(currentTextPage.getOffsetOfLineStart
(currentOutlineRanges[sel].getStartLine()) +
currentOutlineRanges[sel].getStartColumn() - 1,
            currentTextPage.getOffsetOfLineStart
(currentOutlineRanges[sel].getEndLine()) +
currentOutlineRanges[sel].getEndColumn());
          } catch (BadLocationException e1) {
           e1.printStackTrace();
         }
          enableCaretListener = true;
        }
      }
    });
     viewInfo.setComponent(new JScrollPane(customOutlineList));
     viewInfo.setTitle("Custom Outline");
  }
 }
});
```

```
pluginWorkspaceAccess.addEditorChangeListener(new WSEditorChangeListener() {
  /**
  * @see WSEditorChangeListener#editorOpened(java.net.URL)
  */
  @Override
  public void editorOpened(URL editorLocation) {
   //An editor was opened
   WSEditor editorAccess = pluginWorkspaceAccess.getEditorAccess
(editorLocation, StandalonePluginWorkspace.MAIN_EDITING_AREA);
        if(editorAccess != null) {
          WSEditorPage currentPage = editorAccess.getCurrentPage();
          if(currentPage instanceof WSXMLTextEditorPage) {
            //User editing in Text mode an open XML document.
            final WSXMLTextEditorPage xmlTP = (WSXMLTextEditorPage) currentPage;
            //Reconfigure outline on each change.
            xmlTP.getDocument().addDocumentListener(new DocumentListener() {
              @Override
              public void removeUpdate(DocumentEvent e) {
                reconfigureOutline(xmlTP);
              }
              @Override
              public void insertUpdate(DocumentEvent e) {
                reconfigureOutline(xmlTP);
              }
              @Override
              public void changedUpdate(DocumentEvent e) {
                reconfigureOutline(xmlTP);
              }
            });
            JTextArea textComponent = (JTextArea) xmlTP.getTextComponent();
            textComponent.addCaretListener(new CaretListener() {
              @Override
              public void caretUpdate(CaretEvent e) {
              if(currentOutlineRanges != null && currentTextPage != null &&
enableCaretListener) {
                  enableCaretListener = false;
                  //Find the node to select in the outline.
                  try {
                    int line = xmlTP.getLineOfOffset(e.getDot());
                    for (int i = currentOutlineRanges.length - 1; i >= 0; i--) {
              if(line > currentOutlineRanges[i].getStartLine() &&
line < currentOutlineRanges[i].getEndLine()) {
```

```
                        customOutlineList.setSelectedIndex(i);
                        break;
                      }
                    }
                  } catch (BadLocationException e1) {
                    e1.printStackTrace();
                  }
                  enableCaretListener = true;
                }
              }
            });
          }
        }
      }
      /**
       * @see WSEditorChangeListener#editorActivated(java.net.URL)
       */
      @Override
      public void editorActivated(URL editorLocation) {
        //An editor was selected, reconfigure the common outline
        WSEditor editorAccess = pluginWorkspaceAccess.getEditorAccess
(editorLocation, StandalonePluginWorkspace.MAIN_EDITING_AREA);
        if(editorAccess != null) {
          WSEditorPage currentPage = editorAccess.getCurrentPage();
          if(currentPage instanceof WSXMLTextEditorPage) {
            //User editing in Text mode an open XML document.
            WSXMLTextEditorPage xmlTP = (WSXMLTextEditorPage) currentPage;
            reconfigureOutline(xmlTP);
          }
        }
      }
    }, StandalonePluginWorkspace.MAIN_EDITING_AREA);
  }

  /**
   * Reconfigure the outline
   *
   * @param xmlTP The XML Text page.
   */
  protected void reconfigureOutline(final WSXMLTextEditorPage xmlTP) {
    try {
      //These are DOM nodes.
```

```
      Object[] evaluateXPath = xmlTP.evaluateXPath("//doc | //sec");
      //These are the ranges each node takes in the document.
      currentOutlineRanges = xmlTP.findElementsByXPath("//doc | //sec");
      currentTextPage = xmlTP;
      DefaultListModel listModel = new DefaultListModel();
      if(evaluateXPath != null) {
        for (int i = 0; i < evaluateXPath.length; i++) {
          listModel.addElement(evaluateXPath[i]);
        }
      }
      customOutlineList.setModel(listModel);
    } catch(XPathException ex) {
      ex.printStackTrace();
    }
  }

  /**
   * @see WorkspaceAccessPluginExtension#applicationClosing()
   */
  @Override
  public boolean applicationClosing() {
    return true;
  }
}
```

Disable Context-Sensitive Menu Items for Custom Author Actions

Use Case

You want to disable menu items for custom **Author** mode actions depending on the cursor context.

Solution

By default, Oxygen XML Editor does not toggle the enabled/disabled states for actions based on whether or not the activation XPath expressions for that certain **Author** mode action are fulfilled. This is done because the actions can be many and evaluating XPath expression on each cursor move can lead to performance problems. However, if you have your own *ro.sync.ecss.extensions.api.ExtensionsBundle* implementation you can overwrite the method:

`ro.sync.ecss.extensions.api.ExtensionsBundle.createAuthorExtensionStateListener()`

and when the extension state listener gets activated, you can use the API like this:

```
    /**
```

```
     * @see ro.sync.ecss.extensions.api.AuthorExtensionStateListener#activated
(ro.sync.ecss.extensions.api.AuthorAccess)
     */
    public void activated(final AuthorAccess authorAccess) {

      //Add a caret listener to enable/disable extension actions:
authorAccess.getEditorAccess().addAuthorCaretListener(new AuthorCaretListener()
{
    @Override
    public void caretMoved(AuthorCaretEvent caretEvent) {
      try {
        Map<String, Object> authorExtensionActions =
authorAccess.getEditorAccess().getActionsProvider().getAuthorExtensionActions();
        //Get the action used to insert a paragraph. It's ID is "paragraph"
        AbstractAction insertParagraph = (
AbstractAction) authorExtensionActions.get("paragraph");
        //Evaluate an XPath expression in context of the current node
     Object[] evaluateXPath = authorAccess.getDocumentController().evaluateXPath
(".[ancestor-or-self::p]", false, false, false, false);
        if(evaluateXPath != null && evaluateXPath.length > 0 &&
evaluateXPath[0] != null) {
          //We are inside a paragraph, disable the action.
          insertParagraph.setEnabled(false);
        } else {
          //Enable the action
          insertParagraph.setEnabled(true);
        }
      } catch (AuthorOperationException e) {
        e.printStackTrace();
      }
    }
  });
```

When the extension is deactivated, you should remove the *CaretListener* to avoid adding multiple listeners that perform the same functionality.

Dynamically Add Form Controls Using a Styles Filter

Use Case

You want to add form controls using an API.

Solution

Usually, a form control is added from the CSS using one of the built-in form controls *(on page 2491)*. However, in some cases you do not have all the information you need to properly initialize the form control at CSS level. In these cases you can add the form controls by using the API, more specifically *ro.sync.ecss.extensions.api.StylesFilter*.

For instance, if you want a combo box form control and the values to populate the combo are specified inside a file (or they come from a database). Here is how to add the form control from the API:

```
public class SDFStylesFilter implements StylesFilter {

 public Styles filter(Styles styles, AuthorNode authorNode) {
  if(authorNode.getType() == AuthorNode.NODE_TYPE_PSEUDO_ELEMENT
      && "before".equals(authorNode.getName())) {
    authorNode = authorNode.getParent();
   if ("country".equals(authorNode.getName())) {
    // This is the BEFORE pseudo element of the "country" element.
    // Read the supported countries from the configuration file.
    Map<String, Object> formControlArgs = new HashMap<String, Object>();
    formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_EDIT, "#text");
    formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_TYPE,
          InplaceEditorArgumentKeys.TYPE_COMBOBOX);
    // This will be a comma separated enumeration: France, Spain, Great Britain
    String countries = readCountriesFromFile();
    formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_VALUES, countries);
    formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_EDITABLE, "false");

    // We also add a label in form of the form control.
    Map<String, Object> labelProps = new HashMap<String, Object>();
    labelProps.put("text", "Country: ");
    labelProps.put("styles", "* {width: 100px; color: gray;}");
    StaticContent[] mixedContent = new StaticContent[]
          {new LabelContent(labelProps),new EditorContent(formControlArgs)};
    styles.setProperty(Styles.KEY_MIXED_CONTENT, mixedContent);
      }
    }

    // The added form control is the only way the element can be edited.
    if ("country".equals(authorNode.getName())) {
      styles.setProperty(Styles.KEY_VISIBITY, "-oxy-collapse-text");
    }

    return styles;
```

```
  }
}
```

If the execution of the `formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_VALUES, countries);` line consumes too much execution time (for example, if it connects to a database or if it needs to extract data from a very large file), you can choose to delay it until the values are actually needed by the form control. This approach is called *lazy evaluation* and can be implemented as follows:

```
formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_VALUES,
           new LazyValue<List<CIValue>>() {
  public java.util.List<CIValue> get() {
    // We avoid reading the possible values until they are actually requested.
    // This will be a List with CIValues created over countries:
           France, Spain, Great Britain
    return readCountriesFromFile();
  }
});
```

The lazy evaluation approach can be used for the following form controls properties:

- **InplaceEditorArgumentKeys.PROPERTY_VALUES**
- **InplaceEditorArgumentKeys.PROPERTY_LABELS**
- **InplaceEditorArgumentKeys.PROPERTY_TOOLTIPS**

The full source code for this example is available inside the Oxygen SDK.

Dynamically Modify the Content Inserted by the Author

Use Case

You want to insert typographic quotation marks instead of double quotes.

Solution

By using the API you can set a document filter to change the text that is inserted in the document in **Author** mode. You can use this method to change the insertion of double quotes with the typographic quotes.

Here is some sample code:

```
    authorAccess.getDocumentController().setDocumentFilter
(new AuthorDocumentFilter() {
    /**
     * @see ro.sync.ecss.extensions.api.AuthorDocumentFilter#insertText
(ro.sync.ecss.extensions.api.AuthorDocumentFilterBypass, int, java.lang.String)
     */
    @Override
    public void insertText(AuthorDocumentFilterBypass filterBypass,
```

```
int offset, String toInsert) {
      if(toInsert.length() == 1 && "\"".equals(toInsert)) {
        //User typed a quote but he actually needs a smart quote.
        //So we either have to add \u201E (start smart quote)
        //Or we add \u201C (end smart quote)
        //Depending on whether there's already a start smart quote inserted
in the current paragraph.

      try {
        AuthorNode currentNode =
authorAccess.getDocumentController().getNodeAtOffset(offset);
        int startofTextInCurrentNode = currentNode.getStartOffset();
        if(offset > startofTextInCurrentNode) {
          Segment seg = new Segment();
        authorAccess.getDocumentController().getChars(startofTextInCurrentNode,
offset - startofTextInCurrentNode, seg);
          String previosTextInNode = seg.toString();
          boolean insertStartQuote = true;
          for (int i = previosTextInNode.length() - 1; i >= 0; i--) {
            char ch = previosTextInNode.charAt(i);
            if('\u201C' == ch) {
              //Found end of smart quote, so yes, we should insert a start one
              break;
            } else if('\u201E' == ch) {
              //Found start quote, so we should insert an end one.
              insertStartQuote = false;
              break;
            }
          }

          if(insertStartQuote) {
            toInsert = "\u201E";
          } else {
            toInsert = "\u201C";
          }
        }
      } catch (BadLocationException e) {
        e.printStackTrace();
      }
    }
    System.err.println("INSERT TEXT |" + toInsert + "|");
    super.insertText(filterBypass, offset, toInsert);
```

```
  }
});
```

You can find the online Javadoc for `AuthorDocumentFilter` API here: https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/AuthorDocumentFilter.html

An alternative to using a document filtering is the use of a *ro.sync.ecss.extensions.api.AuthorSchemaAwareEditingHandlerAdapter*, which has clear callbacks indicating the source from where the API is called (Paste, Drag and Drop, Typing).

Extend the Java Functionality of an Existing Framework (Document Type)

Use Case

You want to change the way a DocBook 4 `<xref>` displays in **Author** mode based on what element is at the `@linkend`.

Solution

Follow these steps:

1. Create a Maven Java project and add a dependency on the Oxygen XML Editor classes:

   ```
   <dependency>
       <groupId>com.oxygenxml</groupId>
       <artifactId>oxygen-sdk</artifactId>
       <version>${oxygen.version}</version>
   </dependency>
   ```

   where `${oxygen.version}` is the version of Oxygen XML Editor.

   Alternatively, if the project does not use Maven, all the transitive dependencies of the above Maven artifact need to be added to the classpath of the project.

2. Also add the *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\docbook.jar` to the class path of the project.
3. Create a class that extends *ro.sync.ecss.extensions.docbook.DocBook4ExtensionsBundle* and overwrites the method: *ro.sync.ecss.extensions.api.ExtensionsBundle#createLinkTextResolver()*.
4. For your custom resolver implementation you can start from the Java sources of the *ro.sync.ecss.extensions.docbook.link.DocbookLinkTextResolver* (the Java code for the entire DocBook customization is present in a subfolder in the Oxygen SDK).
5. Pack your extension classes in a *JAR (on page 3420)* file. Copy the *JAR* to: *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\custom.jar`.
6. Start Oxygen XML Editor.

7. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association**. Edit the DocBook 4 document type. In the **Classpath** list add the path to the new *JAR*. In the extensions list select your custom extension instead of the regular DocBook one.
8. You can rename the document type and the `docbook` *framework* folder to something else (such as `custom_docbook`) and share it with others. A document type can also be installed using the add-on support *(on page 2407)*.

Impose Custom Options for Authors

Use Case

You want to force *Track Changes (on page 3424)* to be enabled at startup.

Solution

There are two ways to enable *Track Changes* for every document that you open:

1. You could customize the default options *(on page 318)* that are used by your authors and set the **Track Changes - Initial State** option *(on page 191)* to **Always On**.
2. Use an API to toggle the *Track Changes* state after a document is opened in **Author** mode:

```
// Check the current state of Track Changes
boolean trackChangesOn = authorAccess.getReviewController().isTrackingChanges();
if (!trackChangesOn) {
  // Set Track Changes state to On
  authorAccess.getReviewController().toggleTrackChanges();
}
```

Insert an Element with all the Required Content

Use Case

You want to insert a DITA `image` element that points to a certain resource and has required content and you want the required content be automatically inserted.

Solution

The API `ro.sync.ecss.extensions.api.AuthorSchemaManager` can propose valid elements that can be inserted at the specific offset. Using the method `AuthorSchemaManager.createAuthorDocumentFragment(CIElement)`, you can convert the proposed elements to *document fragments (on page 3419)* (which have all the required content filled in) that can then be inserted in the document.

```
    AuthorSchemaManager schemaManager =
this.authorAccess.getDocumentController().getAuthorSchemaManager();

    WhatElementsCanGoHereContext context =
schemaManager.createWhatElementsCanGoHereContext
(this.authorAccess.getEditorAccess().getCaretOffset());

    List<CIElement> possibleElementsAtCaretPosition =
schemaManager.whatElementsCanGoHere(context);
    loop: for (int i = 0; i < possibleElementsAtCaretPosition.size(); i++) {
      CIElement possibleElement = possibleElementsAtCaretPosition.get(i);
      List<CIAttribute> attrs = possibleElement.getAttributes();
      if(attrs != null) {
        for (int j = 0; j < attrs.size(); j++) {
          CIAttribute ciAttribute = attrs.get(j);
          if (ciAttribute.getName().equals("class")) {
            if (ciAttribute.getDefaultValue() != null
                 && ciAttribute.getDefaultValue().contains("  topic/image ")) {
              //Found a CIElement for image
   //Create a fragment that contains all required child elements already built.
              AuthorDocumentFragment frag =
schemaManager.createAuthorDocumentFragment(possibleElement);
              //Now set the @href to it.
              //Ask the user and obtain a value for the @href
              //Then:

          String href = "test.png";
          List<AuthorNode> nodes = frag.getContentNodes();
          if(!nodes.isEmpty()) {
            AuthorElement imageEl = (AuthorElement) nodes.get(0);
            imageEl.setAttribute("href", new AttrValue(href));
          }
          //And insert the fragment.
          this.authorAccess.getDocumentController().insertFragment
(this.authorAccess.getEditorAccess().getCaretOffset(), frag);
          break loop;
        }
      }
    }
  }
}
```

AuthorDocumentFragment Class

Modify the XML Content on Open

Use Case

You want to convert fixed paths in an attribute value to relative paths.

Solution

The Plugins SDK contains a sample plugin type called `WorkspaceAccess`. Such a plugin is notified when the application starts and it can do what you want in a couple of ways:

1. Add a listener that notifies you when the user opens an XML document. Then if the XML document is opened in the **Author** visual editing mode you can use the *Author API* to change attributes:

```
   pluginWorkspaceAccess.addEditorChangeListener(new  WSEditorChangeListener() {
      /**
       * @see WSEditorChangeListener#editorOpened(java.net.URL)
       */
      @Override
      public void editorOpened(URL editorLocation) {
        WSEditor openedEditor = pluginWorkspaceAccess.getCurrentEditorAccess
(StandalonePluginWorkspace.MAIN_EDITING_AREA);
        if(openedEditor.getCurrentPage() instanceof WSAuthorEditorPage) {
        WSAuthorEditorPage authPage = (WSAuthorEditorPage)
openedEditor.getCurrentPage();
        AuthorDocumentController docController =
authPage.getDocumentController();
        try {
         //All changes will be undone by pressing Undo once.
         docController.beginCompoundEdit();
         fixupImageRefs(docController,
          docController.getAuthorDocumentNode());
        } finally {
           docController.endCompoundEdit();
          }
        }
      }

      private void fixupImageRefs
(AuthorDocumentController docController, AuthorNode authorNode) {
          if(authorNode instanceof AuthorParentNode) {
```

```
            //Recurse
            List<AuthorNode> contentNodes =
((AuthorParentNode)authorNode).getContentNodes();
            if(contentNodes != null) {
               for (int i = 0; i < contentNodes.size(); i++) {
                 fixupImageRefs(docController, contentNodes.get(i));
               }
             }
          }
          if(authorNode.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
            AuthorElement elem = (AuthorElement) authorNode;
            if("image".equals(elem.getLocalName())) {
               if(elem.getAttribute("href") != null) {
                 String originalHref = elem.getAttribute("href").getValue();
    URL currentLocation = docController.getAuthorDocumentNode().getXMLBaseURL();
                //TODO here you compute the new href.
                String newHref = null;
              docController.setAttribute("href", new AttrValue(newHref), elem);
               }
            }
        }
      }
    },
  StandalonePluginWorkspace.MAIN_EDITING_AREA);
```

2. An API to open XML documents in the application:

   ```
   ro.sync.exml.workspace.api.Workspace.open(URL)
   ```

   So you can create a plugin that automatically opens XML documents one at a time from a certain folder in the application, makes modifications to them, and saves the content by calling:

   ```
   ro.sync.exml.workspace.api.editor.WSEditorBase.save()
   ```

   then closes the editor by calling:

   ```
   ro.sync.exml.workspace.api.Workspace.close(URL)
   ```

Modify the XML Content on Save

Use Case

You the revised date on a DITA document to be updated when it is saved.

Solution

The Plugins SDK contains a sample plugin type called **WorkspaceAccess**.Such a plugin is notified when the application starts.

You can add a listener that notifies you before the user saves an XML document. Then if the XML document is opened in the **Author** visual editing mode you can use the *Author API* to change attributes before the save takes place:

```
      @Override
      public void applicationStarted
(final StandalonePluginWorkspace pluginWorkspaceAccess) {
       pluginWorkspaceAccess.addEditorChangeListener
(new WSEditorChangeListener(){
         //An editor was opened
        @Override
        public void editorOpened(URL editorLocation) {
          final WSEditor editorAccess = pluginWorkspaceAccess.getEditorAccess
(editorLocation, PluginWorkspace.MAIN_EDITING_AREA);
          if(editorAccess != null){
            editorAccess.addEditorListener
(new ro.sync.exml.workspace.api.listeners.WSEditorListener(){
              //Editor is about to be saved
              @Override
              public boolean editorAboutToBeSavedVeto(int operationType) {
                if(EditorPageConstants.PAGE_AUTHOR.equals
(editorAccess.getCurrentPageID())){
                  WSAuthorEditorPage authorPage =
(WSAuthorEditorPage) editorAccess.getCurrentPage();
                  AuthorDocumentController controller =
authorPage.getDocumentController();
                  try {
                    //Find the revised element
                    AuthorNode[] nodes = controller.findNodesByXPath
("//revised", true, true, true);
                    if(nodes != null && nodes.length > 0){
                      AuthorElement revised = (AuthorElement) nodes[0];
                      //Set the modified attribute to it...
                      controller.setAttribute("modified",
new AttrValue(new Date().toString()), revised);
                    }
                  } catch (AuthorOperationException e) {
                    e.printStackTrace();
                  }
                }
                //And let the save continue..
                return true;
              }
```

```
            });
          }
        }
       }, PluginWorkspace.MAIN_EDITING_AREA);
      }
```

Multiple Rendering Modes for the Same Document in Author Mode

Use Case

You want to add multiple buttons, each showing a different visualization mode of the same document, in **Author** mode.

Solution

In the toolbar in **Author** mode, there is a **Styles** drop-down menu that contains *alternate CSS styles (on page 3417)* for the same document. To add an *alternate* CSS stylesheet, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Type Association**, select the document type associated with your documents and click **Edit**. In the **Document Type** configuration dialog box *(on page 147)* that appears, go to the **Author** tab, and in the **CSS** subtab add references to *alternate* CSS stylesheets.

For example, one of the alternate CSS stylesheets offered for the DITA document type is located here (by default):

```
[OXYGEN_INSTALL_DIR]/frameworks/dita/css_classed/hideColspec.css
```

If you open it, you will see that it imports the *main CSS (on page 3421)* and then adds selectors of its own.

Obtain the Currently Selected Element Using the Author API

Use Case

In **Author** mode, if an element is fully selected, you want to perform an action on it. If not, you want to perform an action on the node that is located at the cursor position.

Solution

When an element is fully selected by the user the selection start and end offsets are actually outside of the node's offset bounds. So using *AuthorDocumentController.getNodeAtOffset* will actually return the parent of the selected node. A special API is available that makes it easier for you to determine this situation: *WSAuthorEditorPageBase.getFullySelectedNode()*.

```
AuthorDocumentController controller = authorPageAccess.getDocumentController();
AuthorAccess authorAccess = authorPageAccess.getAuthorAccess();
int caretOffset = authorAccess.getEditorAccess().getCaretOffset();

    AuthorElement nodeAtCaret =
(AuthorElement) authorAccess.getEditorAccess().getFullySelectedNode();
```

```
    if (nodeAtCaret == null) {
     //We have no fully selected node. We can look at the cursor offset.
     nodeAtCaret = (AuthorElement)
authorAccess.getDocumentController().getNodeAtOffset(caretOffset);
    //Or we could look at the selection start and end, see which node is
the parent of each offset and get the closest common ancestor.
}
```

Open a Document from Another Application

Restriction:
This feature is currently only available for macOS users.

Use Case

You want to open a document from another application in Oxygen XML Editor.

Solution

The Oxygen XML Editor installation kit for macOS comes with a special protocol handler that can be used if you want to open remote resources in the application (for example, opening a file from a CMS). The protocol is **edit-in-oxygen** and you can use it from a command line like this:

```
open edit-in-oxygen:protocol://host/path/file.xml
```

For example, if you start the following from the command line:

```
open edit-in-oxygen:http://www.oxygenxml.com/index.html
```

Oxygen XML Editor will start and open the HTML content from the URL *http://www.oxygenxml.com/index.html*.

Tip:
You can also use anchors on the URL to point to specific lines or elements inside the open document: Opening a Document at a Specific Location Using a Command-Line Interface *(on page 393)*.

Run XSLT or XQuery Transformations

Use Case

You want to run XSL 2.0 / 3.0 transformations with Saxon EE using the *Oxygen SDK*.

Solution

The API class *ro.sync.exml.workspace.api.util.XMLUtilAccess* allows you to create an XSLT Transformer that implements the JAXP interface *javax.xml.transform.Transformer*. Then this type of transformer can be used to transform XML. Here's just an example of transforming when you have an *AuthorAccess* API available:

```
     InputSource is = new org.xml.sax.InputSource
(URLUtil.correct(new File("test/personal.xsl")).toString());
     xslSrc = new SAXSource(is);
     javax.xml.transform.Transformer transformer =
authorAccess.getXMLUtilAccess().createXSLTTransformer
(xslSrc, null, AuthorXMLUtilAccess.TRANSFORMER_SAXON_ENTERPRISE_EDITION);
     transformer.transform(new StreamSource(new File("test/personal.xml")),
new StreamResult(new File("test/personal.html")));
```

If you want to create the transformer from the *plugin* side, you can use this method instead: *ro.sync.exml.workspace.api.PluginWorkspace.getXMLUtilAccess()*.

Save a New Document with a Predefined File Name Pattern

Use Case

You want Oxygen XML Editor to automatically generate a file name comprising a UUID plus file extension using the SDK.

Solution

This could be done implementing a *plugin (on page 3422)* for Oxygen XML Editor using the Plugins SDK.

There is a type of *plugin* called *Workspace Access* that can be used to add a listener to be notified before an opened editor is saved. The implemented *plugin* would intercept the save events when a newly created document is untitled and display an alternative chooser dialog box, then save the topic with the proper name.

The Java code would look like this:

```
  private static class CustomEdListener extends WSEditorListener{
    private final WSEditor editor;
    private final StandalonePluginWorkspace
        pluginWorkspaceAccess;
    private boolean saving = false;
    public CustomEdListener
(StandalonePluginWorkspace pluginWorkspaceAccess, WSEditor editor) {
            this.pluginWorkspaceAccess = pluginWorkspaceAccess;
            this.editor = editor;
    }
    @Override
    public boolean editorAboutToBeSavedVeto(int operationType) {
      if(! saving &&
        editor.getEditorLocation().toString().contains("Untitled")) {
        File chosenDir = pluginWorkspaceAccess.chooseDirectory();
        if(chosenDir != null) {
          final File chosenFile =
```

```
new File(chosenDir, UUID.randomUUID().toString() + ".dita");
        SwingUtilities.invokeLater(new Runnable() {
            @Override
              public void run() {
              try {
                saving = true;
                editor.saveAs(new URL(chosenFile.toURI().toASCIIString()));
              } catch (MalformedURLException e) {
                e.printStackTrace();
              } finally {
                saving = false;
              }
            }
          });
        }

        //Reject the original save request.
        return false;
      }
      return true;
    }
  }

    @Override
    public void applicationStarted
(final StandalonePluginWorkspace pluginWorkspaceAccess) {
    pluginWorkspaceAccess.addEditorChangeListener(new WSEditorChangeListener() {
      @Override
      public void editorOpened(URL editorLocation) {
        final WSEditor editor = pluginWorkspaceAccess.getEditorAccess
(editorLocation, PluginWorkspace.MAIN_EDITING_AREA);
      if(editor !=
null && editor.getEditorLocation().toString().contains("Untitled")) {

        //Untitled editor
 editor.addEditorListener(new CustomEdListener(pluginWorkspaceAccess, editor));
        }
      }
     },
  PluginWorkspace.MAIN_EDITING_AREA);
.........................................
```

Split Paragraph on Enter (Instead of Showing Content Completion List)

Use Case

You want to split the paragraph on **Enter** instead of showing the content completion list.

Solution

Yes, it is possible by creating your own custom operation.

To obtain this behavior, follow this procedure:

1. Create a custom **Author** mode operation *(on page 2295)* that handles the split. You can use the `AuthorDocumentController.split` API to achieve this.
2. Create a JAR library that contains its compiled version.
3. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Document Types Association**, and select your *framework*.
4. Click **Edit** and in the **Document Type** configuration dialog box *(on page 147)*, go to the **Classpath** tab *(on page 152)* and add a reference to the JAR library for your custom operation.
5. Go to the **Author** tab, then go to the **Actions** subtab.
6. Click the **New** button and use the **Action** dialog box *(on page 155)* to create your own paragraph split action.
7. Make sure you assign **Enter** as the **Shortcut Key** and specify your custom operation in the **Operations** section.

Result: Now, when you press **Enter**, your Java operation will be invoked to split the paragraph instead of opening the *Content Completion Assistant*.

> **Tip:**
> The *Content Completion Assistant* can still be invoked by using the **Ctrl+Space** keyboard shortcut.

Use Custom Rendering Styles for Entity References, Comments, or PIs

Use Case

You want to display entity references in the **Author** mode without the distinct gray background and tag markers.

Solution

There is a built-in CSS stylesheet in the Oxygen XML Editor libraries that is used when styling content in the **Author** mode, no matter what CSS you use. This CSS has the following content:

```
@namespace oxy url('http://www.oxygenxml.com/extensions/author');
@namespace xi "http://www.w3.org/2001/XInclude";
@namespace xlink "http://www.w3.org/1999/xlink";
```

```
@namespace svg "http://www.w3.org/2000/svg";
@namespace mml "http://www.w3.org/1998/Math/MathML";

oxy|document {
    display:block !important;
}

oxy|cdata {
    display:morph !important;
    white-space:pre-wrap !important;
    border-width:0px !important;
    margin:0px !important;
    padding: 0px !important;
}

oxy|processing-instruction {
    display:block !important;
    color: rgb(139, 38, 201) !important;
    white-space:pre-wrap !important;
    border-width:0px !important;
    margin:0px !important;
    padding: 0px !important;
}

oxy|comment {
    display:morph !important;
    color: rgb(0, 100, 0) !important;
    background-color:rgb(255, 255, 210) !important;
    white-space:pre-wrap !important;
    border-width:0px !important;
    margin:0px !important;
    padding: 0px !important;
}

oxy|reference:before,
oxy|entity[href]:before{
  link: attr(href) !important;
  text-decoration: underline !important;
  color: navy !important;

  margin: 2px !important;
  padding: 0px !important;
```

```
}

oxy|reference:before {
  display: morph !important;
  content: url(../images/editContent.gif) !important;
}

oxy|entity[href]:before{
  display: morph !important;
  content: url(../images/editContent.gif) !important;
}

oxy|reference,
oxy|entity {
    editable:false !important;
    background-color: rgb(240, 240, 240) !important;
    margin:0px !important;
    padding: 0px !important;
}

oxy|reference {
    display:morph !important;
}

oxy|entity {
    display:morph !important;
}

oxy|entity[href] {
  border: 1px solid rgb(175, 175, 175) !important;
  padding: 0.2em !important;
}

xi|include {

    margin-bottom: 0.5em !important;
    padding: 2px !important;
}
xi|include:before,
xi|include:after{
    display:inline !important;
    background-color:inherit !important;
```

```
    color:#444444 !important;
    font-weight:bold !important;
}

xi|include:before {
    content:url(../images/link.gif) attr(href)  !important;
    link: attr(href) !important;
}
xi|include[xpointer]:before {
    content:url(../images/link.gif) attr(href) " " attr(xpointer) !important;
    link: oxy_concat(attr(href), "#", attr(xpointer)) !important;
}

xi|fallback {
    display:morph !important;
    margin: 2px !important;
    border: 1px solid #CB0039 !important;
}

xi|fallback:before {
    display:morph !important;
    content:"XInclude fallback: " !important;
    color:#CB0039 !important;
}

oxy|doctype {
    display:block !important;
    background-color: transparent !important;
    color:blue !important;
    border-width:0px !important;
    margin:0px !important;
    padding: 2px !important;
}

oxy|error {
    display:morph !important;
    editable:false !important;
    white-space:pre !important;
    color: rgb(178, 0, 0) !important;
    font-weight:bold !important;
}
```

```
*[xlink|href]:before {
    content:url(../images/link.gif);
    link: attr(xlink|href) !important;
}

/*No direct display of the MathML and SVG images.*/
svg|svg{
    display:inline !important;
    white-space: trim-when-ws-only;
}
svg|svg svg|*{
    display:none !important;
    white-space:normal;
}

mml|math{
    display:inline !important;
    white-space: trim-when-ws-only;
}
mml|math mml|*{
    display:none !important;
    white-space: normal;
}
```

In the CSS used for rendering the XML in **Author** mode, do the following:

1. Import the special **Author** mode namespace.
2. Use a special selector to customize the `entity` node.

Example:

```
@namespace oxy url('http://www.oxygenxml.com/extensions/author');
oxy|entity {
   background-color: inherit !important;
   margin:0px !important;
   padding: 0px !important;
    -oxy-display-tags:none;
}
```

You can overwrite styles in the predefined CSS to customize style comments, processing instructions, and *CData* sections. You can also customize the way `<xi:include>` elements are rendered.

19.

Add-ons

Oxygen XML Editor offers various default *add-ons (on page 3422)* that can be installed to provide additional functionality to Oxygen XML Editor. Some additional community submissions are also available, although community add-ons are not officially supported or endorsed. For a full list of *add-ons* that are officially supported for Oxygen XML Editor, see Oxygen XML Add-on Repositories.

This chapter contains information about the default add-ons that are available to install directly from Oxygen XML Editor.

To install one of the default add-ons, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select the add-on you want to install and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Collaboration

Git Client Add-on

An add-on is available that contributes a built-in Git client directly in Oxygen XML Editor. Once the add-on is installed, a **Git Staging** view is available that includes various actions that perform common Git commands, such as *push*, *pull*, *change branch*, *commit*, and more. It also includes a built-in tool for comparing and merging changes.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

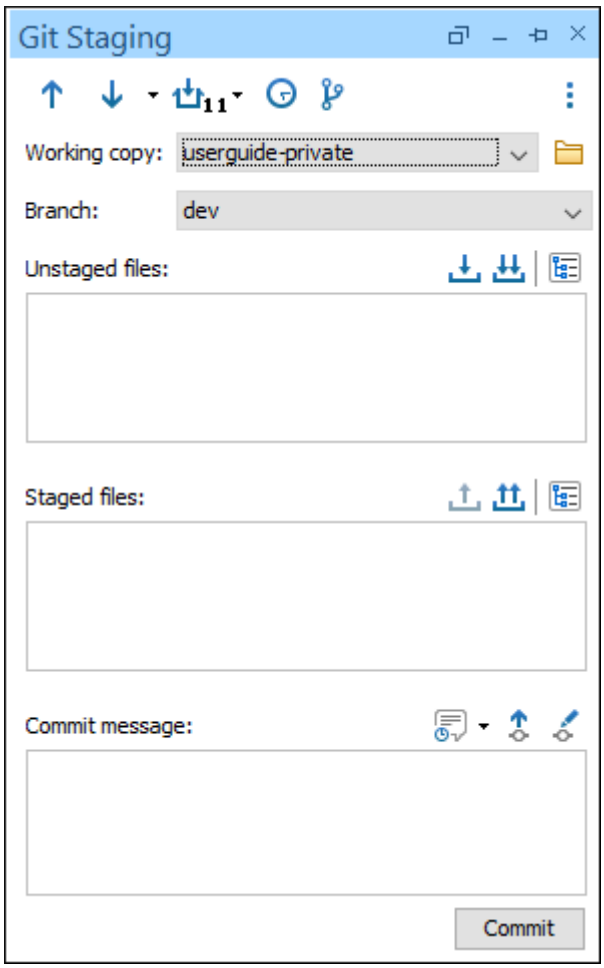
2. Select the **Git Client** add-on and click **Next**.
3. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
4. Restart the application.

Result: The **Git Staging** view is now available. To open the view, select **Git Staging** from the **Window > Show View** menu (or select **Git Client** from the **Tools** menu). This view acts as a Git client integrated directly in Oxygen XML Editor, and it provides support for committing changes to a Git repository, comparing and merging changes, resolving conflicts, and other Git commands. A **Git** menu is also contributed in the main menu bar that includes various Git actions.

Git Staging View Interface

Once the **Git Client** add-on is installed, the **Git Staging** view is available by selecting it from the **Window > Show View** menu (or select **Git Client** from the **Tools** menu). The **Git Staging** view is the main interface where most of the actions that trigger Git commands and other features can be accessed.

Figure 624. Git Staging View



The **Git Staging** view includes the following actions/features (most are also available in the **Git** menu):

Push

Pushes your local repository changes to the remote repository. The arrow icon has a small plus sign in the bottom-right corner when there are changes that have not yet been pushed to the repository.

Pull

Pulls the changes from the remote repository into your local repository.

Stash drop-down menu

Includes the following submenu items:

Stash changes

Creates a new stash from the working copy changed file.

List stashes

Opens a dialog box that lists the existing stashes and you can choose to apply or remove a stash.

Show current repository history

Opens the **Git History** view *(on page 2643)* at the bottom of the application.

Show Git Branch Manager view

Opens the **Git Branch Manager** view *(on page 2647)* on the right side of the application.

Ellipsis (three vertical dots) menu

Includes the following submenu items:

Clone new repository

Clones a repository into a new directory.

Push

Pushes your local repository changes to the remote repository.

Pull (merge)

Pulls the latest changes from the remote repository and combines them with your local unpublished changes by creating one new merge commit.

Pull (rebase)

Pulls the latest changes from the remote repository, rewrites their commits, and reapplies them on top of your local unpublished changes.

Show branches

Opens the **Git Branch Manager** view *(on page 2647)* on the right side of the application.

Show tags

Opens a dialog box that lists all the tags. You can delete tags, checkout a certain tag, or push a tag that is only present in the local branch to the remote.

Show history

Opens the **Git History** view *(on page 2643)* at the bottom of the application.

Submodule

Opens a combo box where you can select the desired submodule to open and work with.

Stash changes

Creates a new stash from the working copy changed file.

List changes

Opens a dialog box that lists the existing stashes and you can choose to apply or remove a stash.

Manage remote repositories

Opens a dialog box where you can add, edit, or delete existing remote repositories.

Track remote branch

Opens a dialog box where you can select a remote branch that the local branch will track for executing fetch, push, or pull commands.

Edit repository "config" file

Opens the configuration file for the repository in the main editor so that it can be edited.

Preferences

Opens the **Git Client** preferences page where you can configure some options that relate to the add-on.

Reset all credentials

Resets all credentials to the default values.

Unstaged files area

Any changed, unstaged files are listed in this box. The following actions are available at the top-right corner of the box:

 **Stage selected**

Moves the selected unstaged, changed files to the **Staged files** area.

 **Stage all**

Moves all unstaged, changed files to the **Staged files** area.

 **Switch to tree view**

Switches to a tree-like view.

Staged files area

All staged files are listed in this box. The following actions are available at the top-right corner of the box:

 **Unstage selected**

Moves the selected staged files to the **Unstaged files** area.

 **Unstage all**

Moves all staged files to the **Unstaged files** area.

 **Switch to tree view**

Switches to a tree-like view.

Commit message area

This box in this area is used to write a commit message. The following actions are available at the top-right corner of the box:

Choose a previously used comment

Allows you to re-use a commit message that you used in the past.

Automatically push changes to remote branch

When a commit is performed, the committed changes are also pushed to the remote repository.

Ammend last commit

Allows you to edit the selected commit. You can combine staged changes with the previous commit instead of creating an entirely new commit. It can also be used to simply edit the previous commit message without changing its snapshot. This action should not be performed on public commits (commits that were pushed to the remote repository).

Cloning a Repository

Click the **Clone new repository** button (it has a '+' sign as the icon) and provide the following:

- **Repository URL** - The URL of the remote repository to be cloned.
- **Checkout branch** - A specific branch of the repository that is being cloned. The default branch will be cloned if another one is not specified.
- **Destination path** - The local path where the repository will be cloned. When you enter a URL of a repository, it will be proposed to automatically save it in a folder with the same name.

After cloning a repository, it will automatically be set as the current working copy.

Making an Oxygen Project a Git Repository

When showing the **Git Staging** side-view after opening an Oxygen XML Editor project that is not already a Git repository, Oxygen XML Editor offers the possibility to make that project also a local Git repository. This is very useful, for example, for newly created projects. After creating the local repository, bind it to a remote repository. You will be asked to specify the URL of the corresponding remote repository on your first attempt to push or pull changes.

Authentication

The *Git Client* supports **HTTPS** and **SSH** connections to GitHub, GitLab, Bitbucket, and more. It also includes support for `ssh-agent` forwarding.

Note:
For SSH connections, you can use the SSH agent to use the SSH keys already stored on it. To enable support for SSH agent access, go to **Git(Menu) > Settings > Preferences > SSH Connections** (or **Git Staging View > Ellipsis menu > Preferences > SSH Connections**) and select the **Use SSH Agent** option.

To access the remote repository, you need to provide your authentication details (if not using unprotected SSH keys). If no such information is found in the add-on's settings, you will be prompted for them.

The *Git Client* allows you to authenticate over HTTPS by using either a basic authentication method (username + password) or a personal access token.

Notes:

- The authentication using personal access tokens has been tested with GitHub and GitLab.
- Bitbucket uses a concept similar to personal access tokens, named *app passwords*. An app password must be provided as the password for *Basic authentication*, along with the correct username.
- As of August 13, 2021, GitHub will no longer accept password-based authentication.

If you have the **two-factor authentication (2FA)** enabled for GitHub or GitLab, to authenticate over HTTPS, you must generate a personal access token for your profile, and back in the *Git Staging* view in Oxygen XML Editor, use the generated token value as the authentication password when asked for your credentials.

If, for example, you have been using a GitHub account but you decide to switch to another GitHub account, you would need to reset your credentials so that you will be prompted for new ones. This is because only one set of credentials for each Git platform/server is stored. To reset your credentials, go to the toolbar at the top of the **Git Staging** side-view, click the settings icon (a cogwheel), and select **Reset all credentials**.

Selecting a Working Copy

Click the **Browse** button to the right of the **Working copy** combo box to select a working copy from your file system. The selected folder must be a Git repository.

Switching Between Local Branches

To switch between local branches from the **Git Staging** view, use the **Branch** combo box. Local branches can also be changed using the **Git Branch Manager** *(on page 2647)*.

New branches can be created from the **Git Branch Manager** *(on page 2647)* or from the **History** table using the **Create branch** action in the contextual menu.

Stashing Files

A Git stash is a way of temporarily saving the changes you have made to your working copy so that you can continue to use other Git operations in the meantime, and you can then re-apply the stashed changes later.

On the toolbar, there is a **Stash** drop down menu with a **Stash changes** action for creating a new stash out of the working copy changed file and a **List stashes** action that presents a dialog box with the existing stashes. From, the **List stashes** dialog box, you can also choose to apply or remove a stash.

Creating Tags

Tagging is used to capture a specific point in history, for example to mark a release. A tag is like a branch that doesn't change. You can create tags from the **History view** *(on page 2643)* contextual menu. In the *Ellipsis (three vertical dots)* menu on the right side of the **Git Staging** view's toolbar, there is a **Show tags** action that lists all the tags. Both local and already pushed tags can be deleted from this dialog box. For tags present only in the local branch, you can choose to push them to the remote repository. The **Show tags** action is also available in the **Git** menu from the main menu bar.

Working with Submodules

When cloning a repository that contains submodules, all submodules are initialized and cloned as well. When pulling changes from the remote repository, the submodules are also updated. The update of the submodules when performing a pull operation depends on the **Update all submodules after pulling changes from the remote repository** option from **Options > Preferences > Plugins > Git Client** (the option is enabled by default).

When checking out a branch for a parent repository with submodules, the submodules are also checked out at the index in the parent repository to reflect the actual state of the repository at that particular time.

To open and work with a Git submodule, use the **Submodules** action from the *Ellipsis (three vertical dots)* menu (on the right side of the **Git Staging** view's toolbar) and select the desired submodule from the presented combo box. As an alternative, if the submodule is modified and is presented in the **Unstaged files** area *(on page 2645)*, the **Open** contextual menu action can be used to open it.

The tooltip of a modified submodule shown in the **Unstaged files** area *(on page 2645)* presents information about the currently and previously tracked commits.

Showing the Repository History

To show the history, invoke the **Show current repository history** action from the toolbar of the *Git Staging* panel (look for the clock icon) or go to **Window > Show view > Git History**. This opens the **Git History** view at the bottom of the application.

In the toolbar, you can choose which branches will have the history shown. You have the following options:

- **Current branch** - Shows the commits for the current branch, including unpushed local and unpulled remote commits.
- **Current local branch** - Shows the commits only for the current local branch, including unpushed local commits.
- **All branches** - Shows the commits for all branches (both local and remote), including unpushed local and unpulled remote commits.
- **All local branches** - Shows the commits only for local branches, including unpushed local commits.

For each commit in the history table, the following actions are available:

- **Create branch** - Used to create a new branch starting from the selected commit. The new branch is automatically checked out by default. To disable this behavior, deselect the **Checkout branch** option in the *Create branch* dialog box.

  > **Tip:**
  > To publish a new branch to the remote repository and start tracking that branch, you need to simply push the local branch using the dedicated action from the **Git Staging** side-view.

- **Create tag** - Used to create a new tag on the selected commit. You have the option to push the tag to the remote repository.
- **Checkout** - Used to checkout a branch at a specific commit (either in detached head form or by creating a new branch at that commit).
- **Revert commit** - Used to create a new commit that reverts all the changes from the selected commit.
- **Reset "[branch_name]" to this commit** - Used to undo changes by moving the HEAD of the current branch to the selected commit.

The **Git History** view presents all the affected resources for each commit in a list, in the bottom-right area. It includes a text filter field at the top that you can use to conduct searches (e.g. by Date, Author, or Commit ID). An included revision graph helps you to understand how commits connect with one another. For each resource, the following actions are available in the contextual menu:

- **Open** (available for added and modified resources) - This action opens the selected resource.
- **Open previous version** (available for deleted resources) - This action opens the version of the selected resource from before its deletion.
- **Open working copy version** (available for added and modified resources) - This action opens the working copy version of the selected resource. It also works if the resource has been renamed in between versions.
- **Reset file to this commit** (available for added and modified resources) - This action checks out the selected version of the resource, overwriting its current version. It does not work if the resource has been renamed or deleted in between versions.
- **Compare with previous version** (available for modified resources) - This action compares the selected version of the selected resource with the previous one using the **Compare Files** tool *(on page 484)*.
- **Compare with working copy version** (available for modified resources) - This action compares the selected version of the selected resource with the current one using the **Compare Files** tool *(on page 484)*.
- **Compare with each other** (available when selecting 2 versions of a single file) - This action compares the selected versions with each other using the **Compare Files** tool *(on page 484)*.

Blame

The contextual menu of each unstaged resource contains a **Show blame** action that opens the selected resource in the main editing area and colors the editor lines with different colors based on the revision

information. Selecting a line in the opened editor will highlight the corresponding entry from the history table in the **Git History** side-view.

This action is also available in the contextual menu of the current editor and of the Git resources from the **Project** side-view *(on page 413)*.

Unstaged Files Area

In the **Unstaged files** area, you will see all the modifications that have occurred in your working copy (files that have been modified, new files, and deleted files) and are not part of the next commit.

- Various actions are available in the contextual menu (**Open**, **Open in compare editor**, **Stage**, **Discard**, **Show history**, **Show blame**, and more).
- You can stage files (i.e. move them to the **Staged files** area *(on page 2645)*) using the actions from the toolbar found above the top-right corner of this area. You can choose between staging all the files, by clicking the **Stage all** button (double arrow icon), and staging specific files, by selecting them and clicking the **Stage selected** button (single arrow icon).
- You can switch between the list view and the tree view by clicking on the **Switch to tree/list view** button positioned to the right of the staging buttons.

Staged Files Area

In the **Staged files** area, you will see all the resources that are ready to be committed. The files from this area can be unstaged and sent back to the **Unstaged files** area *(on page 2645)*. This area has actions similar to those from the **Unstaged files** area *(on page 2645)*, with the exception of the **Show history** and **Show blame** actions that are not available here.

Comparing Changes and Conflict Resolution

At any time, if you want to see the differences between the last commit and your current modifications, you can double-click a file from either the **Unstaged files** area *(on page 2645)* or **Staged files** area *(on page 2645)*, and the **Compare Files** *(on page 484)* window will appear and highlight the changes.

If the file has a conflict (has been modified both by you and another), **Oxygen's 3-Way file comparison** feature *(on page 487)* will show a comparison between the local change, the remote change, and the original base revision.

Committing

After staging the files, on the bottom of the view you can provide a commit message and commit them to your local repository. For convenience, you can also select a previously provided message.

In the toolbar above the **Commit message** text area, there are a few toggle buttons that affect your commit if they are enabled:

- **Amend last commit** - Enabling this option is a convenient way to modify the most recent commit. It lets you combine staged changes with the previous commit instead of creating an entirely new commit. It can also be used to simply edit the previous commit message without changing its snapshot. This action should not be performed on public commits (commits that were pushed to the remote repository).
- **Automatically push changes to remote when committing** - If this option is enabled, when a commit is performed, the committed changes are also pushed to the remote repository.

Push/Pull (with Merge or Rebase)

To push your local repository changes to the remote repository, use the **Push** button from the view's toolbar (up arrow).

To bring the changes from the remote repository into your local repository, use one of the actions from the **Pull** drop-down menu located on the toolbar (). You can choose between **Pull (merge)** and **Pull (rebase)**. The invoked action is promoted as the current action of the toolbar button.

Note:
When pushing a local branch that does not have a corresponding remote branch, a remote branch will automatically be created with the same name as the local branch.

File Conflict Solving Workflow

After editing a file, committing it to the local repository, and trying to push it to the remote repository, if a warning appears about not being up to date with the repository, follow these steps:

1. Pull the data from the repository using one of the *Pull* actions.
2. In the **Unstaged files** area *(on page 2645)*, select each conflicted file and resolve the conflicts. You can do this, for example, by opening the conflicted files in the compare editor, either by double-clicking on them or by using the contextual menu action, and then choose what changes you want to keep and discard, and save the document. You can also use the **Resolve using Mine**, **Resolve using Theirs**, or **Mark as resolved** actions from the contextual menu of a resource.
3. If you choose to use the compare editor, after you close it, the file will be staged automatically and moved to the **Staged files** area *(on page 2645)*.

At this point, the next actions depend on which *Pull* action was chosen:

- **Pull (merge)**:
    1. When all the conflicts are resolved and no more files are left in the **Unstaged files** area *(on page 2645)*, the changes can be committed.
    2. Enter a message and commit. You will now have new changes to push.
    3. Push the changes to the remote repository.

> **Note:**
> You can abort the merge by clicking the **Abort merge** button. This will revert the repository to its previous state prior to the pull attempt.

- **Pull (rebase)**:
  1. When all the conflicts are resolved, click the **Continue rebase** button.
  2. Push any outgoing changes.

> **Note:**
> You can abort the rebase by clicking the **Abort rebase** button. This will revert the repository to its previous state prior to the pull request.

Working with Large Files in Git

Git repositories are designed to track changes to text-based files, such as source code, and are optimized for small file sizes. Large binary files (such as image or video files) can slow down the Git repository and make version control difficult. Git's *Large File Storage (LFS)* provides a solution to this problem by efficiently storing and managing large files outside of the repository.

To start using LFS, follow the instructions at https://git-lfs.com/. Once you have installed LFS and defined the tracked large files in your repository, large files will be automatically detected and handled properly.

> **Warning:**
> If you are using a proxy, you need to set the HTTPS_PROXY environment variable for git operations that involve LFS for it to work correctly.

Setting the HTTPS_PROXY environment variable on Windows from the command line

```
set HTTPS_PROXY=http://my.proxy.com:5000
```

The Project View and the Current Editor

For resources from Git repositories, this add-on also contributes a variety of actions in the contextual menus of the **Project** side-view *(on page 413)* and the current editor (**Text** and **Author** modes). These actions include: **Show history**, **Show blame**, **Git Diff** (only in the *Project* view), and **Commit** (only in the *Project* view).

Git Branch Manager

To show all the local and remote branches, click the **Show Git Branch Manager** button on the toolbar of the *Git Staging* panel (look for the branches icon) or select **Git Branch Manager** from **Window > Show view**. By default, the *Git Branch Manager* is presented to the right of the editing area.

The *Git Branch Manager* side-view displays all the branches as a tree. The tree can be filtered using the text field at the top of the panel and you can reload the information by using the **Refresh** action. When hovering the

cursor over a branch name, a tooltip is displayed that provides information about the last commit performed on that branch (such as the author and the date of the commit).

The following actions are available in the contextual menu for each local branch:

- **Checkout** - Checks out the selected branch and switches the local repository to the selected branch.
- **Create branch** - Creates a new branch using the selected branch as the starting point. The new branch is automatically checked out by default. To disable this behavior, deselect the **Checkout branch** option in the *Create branch* dialog box.

  > **Tip:**
  > To publish a new branch to the remote repository and start tracking that branch, you need to simply push the local branch using the dedicated action from the **Git Staging** side-view.

- **Merge "SELECTED_BRANCH" into "CURRENT_BRANCH"** - Merges all the changes from *SELECTED_BRANCH* into *CURRENT_BRANCH*.
- **Squash merge "SELECTED_BRANCH" into "CURRENT_BRANCH"** - Merges all the changes made on the *SELECTED_BRANCH* since it diverged from the *CURRENT_BRANCH*, on top of the *CURRENT_BRANCH*, and it records the results in a new commit.
- **Delete** - Deletes the selected branch.

For the remote branches, the **Checkout branch** action checks out the selected branch and creates a local branch from the selected remote branch.

Preferences

The *Git Client* add-on contributes a preferences page to Oxygen XML Editor. To access it, go to **Options > Preferences > Plugins > Git Client** or **Git(Menu) > Settings > Preferences** or click the **Ellipsis menu** button from the toolbar of the **Git Staging** view and select **Preferences**. This preferences page includes the following options:

- **When detecting a Git repository inside a newly opened project** - This determines what happens to the current working copy when a project that contains a Git repository is opened in the **Project** side-view *(on page 413)*. You can choose between:
  - **Always switch to the new working copy**
  - **Never switch to the new working copy**
  - **Always ask** (default value)
- **Notify me about new commits in the remote repository** - When this option is selected, Oxygen XML Editor will show notification messages when it detects that new commits have been pushed to the remote repository. By default, this option is not selected.

- **Update all submodules after pulling changes from the remote repository** - If this option is selected, when a repository is updated using the *Pull* operation, all sub-modules are updated as well. This option is selected by default.
- **Detect and open Oxygen projects (.xpr) from opened working copies** - If this option is selected (by default, it is not selected) and a working copy that contains one or more project files (`.xpr`) is opened:
  - If one `.xpr` file is found, it will be opened automatically.
  - If more than one `.xpr` files are found and none of them are opened, a dialog box will appear where the `.xpr` can be selected.
- **Validate each file before commiting** - When this option is selected, each file to be committed will be validated individually. If validation problems are detected, the commit operation will be stopped and a dialog box will appear informing you that the problems can be viewed in the "Results" area (in the "Git pre-commit validation" tab). If the **Reject commit when validation problems occur** option is selected (the default state), the dialog box will include a **Commit anyway** button that allows the commit operation to be completed even if validation issues have been found.
- **Validate all files from the project's "Main Files" folder before pushing** - When this option is selected, the files in the "Main Files" folder will be validated.

  The following are required for this option to function properly:
  - **Main Files** support must be enabled *(on page 429)* and the files must be properly inserted in the "Main Files" folder.
  - It is mandatory that a validation scenario be configured because the validation will be based on it.
  - The current repository must be the same as the project loaded in the **Project View** and there must be no uncommitted changes (if detected, a dialog box will appear offering the option to make a stash be applied after the project validation).

  If validation problems are detected, the push operation will be stopped and a dialog box will appear informing you that the problems can be viewed in the "Results" area (in the "Git pre-push validation" tab). If the **Reject push when validation problems occur** option is selected (the default state), the dialog box will include a **Push anyway** button that allows the push operation to be completed even if validation issues are detected.
- **Global Options/Project Options** - If you select **Project Options**, the settings are stored in the project file (`.xpr`) that can easily be shared with other users *(on page 322)*.

Under the preferences page, there is the "SSH Connections" page, which includes the following options:

- **Use SSH agent** - when this option is selected, the selected SSH agent support is used to benefit from the SSH keys already stored in it. On **Linux**, **OS X**, and **BSD**, the only agent communication mechanism supported is the usual communication via a Unix domain socket. On Windows you can choose between:
  - **Pageant**
  - **Win 32 Open SSH**(default value)

Editor Variables

The *Git Client* contributes the following editor variables:

- **${git(working_copy_name)}** - The name of the working copy directory.
- **${git(working_copy_path)}** - The absolute file path of the working copy directory.
- **${git(working_copy_url)}** - The location of the working copy directory as a URL.
- **${git(short_branch_name)}** - The short name of the current branch (e.g. `dev`).
- **${git(full_branch_name)}** - The full name of the current branch (e.g. `refs/heads/dev`).

Project Validation

Validating Each File Before a Commit

To enable automatic validation of each file before a commit, select the **Validate each file before committing** option *(on page 2649)* in the **Git Client** preferences page (**Git > Settings > Preferences**, or **Options > Preferences > Plugins > Git Client**, or click the **Settings** button from the toolbar of the **Git Staging** view and select **Preferences**).

If validation problems are detected, the commit operation will be stopped and a dialog box will appear informing you that the problems can be viewed in the "Results" area (in the "Git pre-commit validation" tab). If the **Reject commit when validation problems occur** option is selected, the dialog box will include a **Commit anyway** button that allows the commit operation to be completed even if validation issues have been found.

Validating Before a Push Operation

To enable automatic validation of the files from the "Main Files" folder, select the **Validate all files from the project's "Main Files" folder before pushing** option *(on page 2649)* in the **Git Client** preferences page (**Git > Settings > Preferences**, or **Options > Preferences > Plugins > Git Client**, or click the **Settings** button from the toolbar of the **Git Staging** view and select **Preferences**).

For this option to function properly, **Main Files** support must be enabled *(on page 429)* and the files must be properly inserted in the "Main Files" folder. It is also mandatory that a validation scenario be configured because the validation will be based on it. The current repository must be the same as the project loaded in

the **Project View** and there must be no uncommitted changes (if detected, a dialog box will appear offering the option to make a stash be applied after the project validation).

If validation problems are detected, the push operation will be stopped and a dialog box will appear informing you that the problems can be viewed in the "Results" area (in the "Git pre-push validation" tab). If the **Reject push when validation problems occur** option is selected, the dialog box will include a **Push anyway** button that allows the push operation to be completed even if validation issues are detected.

Content Fusion Connector Add-on

An **Oxygen Content Fusion Connector** add-on is available that can be installed to integrate **Oxygen Content Fusion** with Oxygen XML Editor. **Content Fusion** is a flexible, intuitive collaboration platform designed to adapt to virtually any type of workflow that a collaborative team may use for their documentation review process.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the **Oxygen Content Fusion Connector** add-on in **Oxygen XML Editor** or **Oxygen XML Author**, follow these steps:

1. Go to **Window > Show View** and select **Content Fusion Task Manager**.
2. If it has not already been installed, a message will appear asking you if you want to install the add-on.
3. To continue, click **Install** and follow the on-screen instructions.

   Note:
   If you don't see the add-on because Oxygen XML Editor is unable to connect to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

4. Restart Oxygen XML Editor.

Result: **Content Fusion Task Manager** is now available in the **Window > Show View** menu. Selecting this button/action opens the **Content Fusion Task Manager** view.

To fully take advantage of all of the benefits and features, your organization will need an **Oxygen Content Fusion Enterprise Server**. This solution allows you to host, setup, and configure your own server and control your data. With this model, you are also able to upload custom frameworks and plugins, and to configure various settings. It is possible to evaluate **Content Fusion** free of charge, for a limited time. For more information, see the **Oxygen Content Fusion** website.

For more information about using **Content Fusion** in Oxygen XML Editor, see the **Oxygen Content Fusion User Guide**.

Integrating Oxygen Feedback with Oxygen XML Editor/Author

It is possible to integrate **Oxygen Feedback** with *Oxygen XML Editor/Author* so that your documentation team can see all the comments added in your WebHelp output. This means they can react to user feedback by making corrections and updating the source content without leaving the application. This is made possible by an add-on that when installed in **Oxygen XML Editor/Author**, a **Feedback Comments Manager** view becomes available.

Attention:
The **Feedback Comments Manager** view only functions in **Oxygen XML Editor** or **Oxygen XML Author**. It does not work in the **Oxygen XML Developer** edition.

To see a demonstration of **Oxygen Feedback** being integrated with *Oxygen XML Editor/Author*, watch our Webinar: **DITA Publishing and Feedback with Oxygen Tools**.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install this add-on in *Oxygen XML Editor/Author*, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select **Oxygen Feedback Connector** add-on and click **Next**.

4. Select the **I accept all terms of the end user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **Feedback Comments Manager** view is now available. By default, it is displayed to the right of the main editing panel. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu. You can also use the **Show Feedback Comments Manager** from the contextual menu in the **DITA Maps Manager**.

Connecting the Feedback Comments Manager View

If this is your first time using it, you need to configure a mapping between *Oxygen XML Editor/Author* and your Feedback site configuration(s). If you have already configured a mapping, you just need to connect the **Feedback Comments Manager** to your Feedback account.

To connect, follow this procedure:

1. Select **Connect** from the user drop-down menu at the top-right corner of the **Feedback Comments Manager**.

   Step Result: You are directed to the *administration login page* in your default browser.
2. Log in with your credentials, click **Authorize** in the resulting page, and go back to *Oxygen XML Editor/Author*.
3. If this is your first time using the **Feedback Comments Manager**, you need to configure a mapping:
   a. Select **Preferences** from the user drop-down menu at the top-right corner of the **Feedback Comments Manager**.

      Step Result: You are directed to the **Oxygen Feedback Connector** preferences page (you can also reach this page by going to **Options > Preferences > Plugins > Oxygen Feedback Connector**).

   b. Click the **New** button at the bottom of the mappings table.

      Step Result: This opens the **New Oxygen Feedback Mapping** dialog box where you can configure the mapping.

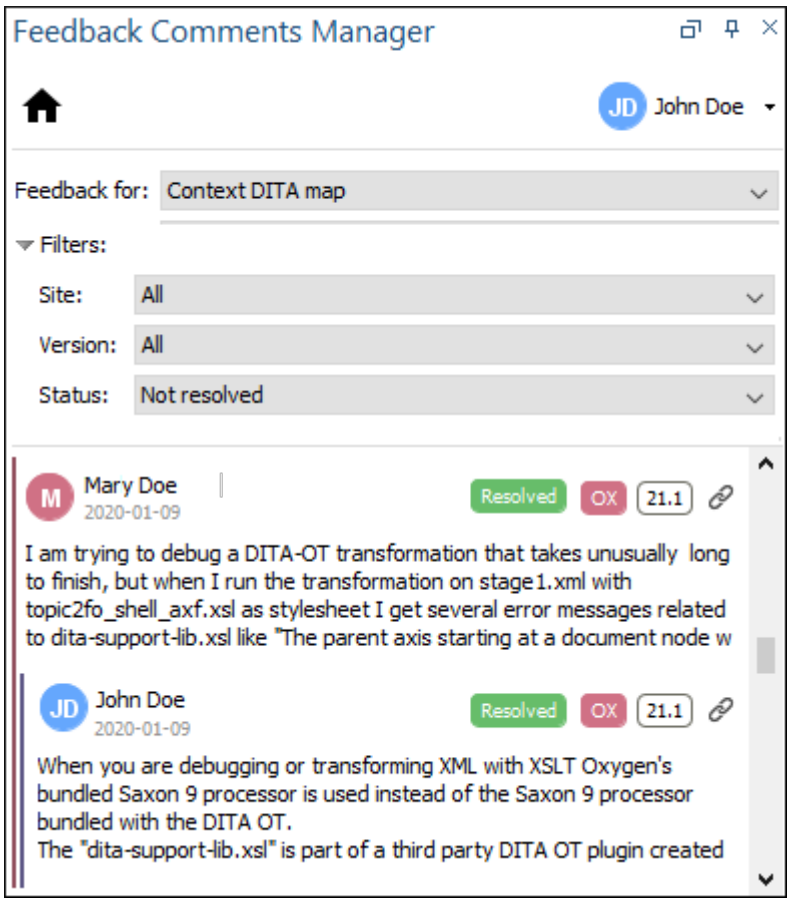
   c. In the **Context DITA map location** field, click the browsing button and specify the URL of your context DITA map. This is the path to the root DITA map used to publish your output.
   d. For the **Published site base URL** field, *Oxygen XML Editor/Author* automatically detects all the base URLs for the site configurations that you have the role of *Moderator*, *Admin*, or *Owner*. You can type the base URL or select it from the drop-down menu.
   e. Click **OK** in both dialog boxes.

Result: The comments that exist in the published WebHelp output for the site configurations attached to the current user's organization (based on the configured mapping) will be loaded in the **Feedback Comments Manager** view.

Using the Feedback Comments Manager View

If the view is not already open in *Oxygen XML Editor/Author*, go to **Window > Show View > Feedback Comments Manager**. You can also use the **Show Feedback Comments Manager** from the contextual menu in the **DITA Maps Manager**.

Figure 625. Feedback Comments Manager View



The **Feedback Comments Manager** view contains the following actions and components:

Home button

Use this button to open the **Oxygen Feedback** administration interface in your default browser.

User Name drop-down menu

Once connected and authorized, your user name will appear in the upper right corner of the view. The drop-down menu offers the following actions:

Refresh

Forces a refresh to synchronize the information in the view and reloads the first 20 items.

Preferences

Opens the **Oxygen Feedback Connector** preferences page where you can configure a mapping between *Oxygen XML Editor/Author* and your Feedback site configuration(s).

Help

Opens the **Oxygen Feedback** user guide in your default browser.

Connect/Disconnect

Signs you in or out of your **Oxygen Feedback** account.

Feedback for

You can choose which display mode to use for retrieving comments. The options are:

- **Context DITA map** - If there are base URLs mapped to the current context map, comments from all versions defined by the given base URLs will be loaded.
- **Current editor** - Only comments added in the output for the current topic will be loaded. This mode will retrieve comments from web pages generated from any DITA source file (`.dita` file extension) as well as any source file with a file extension of `xml`, `html`, or `md`.

Filters

You can apply filters for **Site**, **Version**, and **Status**:

Site

You can choose to show **All** site configurations that you are assigned as *Moderator*, *Admin*, or *Owner* or you can choose a specific site configuration.

Version

You can choose show **All** versions for the site configurations that you are assigned as *Moderator*, *Admin*, or *Owner* or you can choose a specific version for the specified site configuration. If the **Site** filter is set to *All*, this drop-down includes the name for all the versions available for the currently detected sites. If there are multiple versions with the same name, the name will be shown only once, but the filtering will detect all the versions with the selected name.

Status

You can choose between:

- **Not resolved (Pending, Open, Reopened)** - Displays comments that are in a state of *Pending*, *Open*, or *Reopened*.
- **Pending** - Only displays comments that are in a *Pending* state.
- **Open** - Only displays comments that are in an *Open* state.
- **Reopened** - Only displays comments that are in an *Reopened* state.
- **Resolved** - Only displays comments that are in a *Resolved* state.
- **All** - Displays all comments.

> **Note:**
> The filters are persistent between sessions. If the comments are retrieved for the **Context DITA map**, they are saved in options associated with the context map. Otherwise, they are associated to a ditamap that is determined from the one that is set in the mapping preferences.

Comments Area

> **Note:**
> Comments are only retrieved for site configurations that you have the role of *Moderator*, *Admin*, or *Owner*.

In the comments area, each comment is displayed as its own box and they are grouped by the topic title or path of the web page where the comments were added and then sorted by date (most recent first). If a DITA topic from context map (or the current topic) can be computed from the web page where a comment is added, you can double-click anywhere in the comment box to open the topic in the main editor. You can also click the group name (the topic title or path) to open the particular topic in the WebHelp output, in your default browser.

At the bottom-right corner of the comment box for each first-level comment (a comment that is not a reply), there is a link to **Resolve** or **Reopen** the comment. The **Resolve** action is only available for first-level comments (not replies) and it marks the comment as *Resolved*. The **Reopen** action is only available for resolved comments and it marks the comment as *Reopened*.

> **Note:**
> If a new reply is added to a thread that is marked as *Resolved*, the thread is automatically marked as *Reopened*.

Each comment box also includes the commenter's name and avatar, the time the comment was added, the state of the comment (e.g. *Open*, *Rejected*, *Deleted*, *Resolved*, *Reopened*), the initials of the site configuration, the version number, a link to open the WebHelp topic in your browser (the most specific URL for a version is used), and the content of the comment (up to 4 lines). If you hover over a status badge for comments whose status is *Rejected*, *Deleted*, or *Resolved*, you can see the user name who changed the status and the time it was changed.

If there are more than 20 top-level comments, the comments are retrieved in chunks of 20 (replies are not limited) and there is a **Load more comments** button at the bottom that will retrieve the next chunk of top-level comments.

Contextual Menu

If you right-click anywhere in a comment box, the contextual menu offers the following actions:

Open topic

If the **Feedback for** option is set to *Context DITA Map* and a parent file (from the current DITA map hierarchy) could be determined, selecting this option opens the parent document in the main editor. If the **Open topic** action is executed on a *block-level comment*, the parent document is opened and the element that the block-level comment is attached to is highlighted in **Author** mode (or the cursor is placed at the beginning of the element in **Text** mode).

Copy content (Ctrl + C)

Copies the content of the comment to the system clipboard.

Show comment

Opens a dialog box with the entire comment displayed. You can copy selected content from the comment to the system clipboard by clicking the **Copy** button at the bottom of the dialog box. If not content is selected, it copies the entire content of the comment.

Migration/Conversions

Batch Documents Converter Add-on

Oxygen XML Editor offers an add-on that contributes actions in the following submenus:

- **Batch Documents Converter** submenu located in the **Tools** menu and the contextual menu of resources in the **Project** view.
- **Additional conversions** submenu located in **File > Import/Convert**.
- **Import** submenu located in the **Append child**, **Insert Before**, and **Insert After** submenus from the contextual menu of the **DITA Maps Manager** view when the opened DITA map is a local file.

The first time you invoke any of these actions, Oxygen XML Editor will ask you if you want to install it and offer a wizard to help with the installation process.

Once installed, you need to restart Oxygen XML Editor and those same actions will then contain the list of available conversions. Selecting an action from the submenu will open a dialog box where you can configure the options for the corresponding conversion. You can batch convert between the following formats:

- HTML to XHTML
- HTML to DITA
- HTML to DocBook4
- HTML to DocBook5
- Markdown to XHTML
- Markdown to DITA
- Markdown to DocBook4
- Markdown to DocBook5
- Word (`.doc` or `.docx`) to XHTML
- Word (`.doc` or `.docx`) to DITA

- Word (`.doc` or `.docx`) to DocBook4
- Word (`.doc` or `.docx`) to DocBook5
- Excel to DITA
- Confluence to DITA
- DocBook to DITA
- OpenAPI to DITA
- JSON to XML
- XML to JSON
- JSON to YAML
- YAML to JSON
- YAML to XML
- XML to YAML
- XSD to JSON Schema (version 2020-12)

When actions are invoked from the contextual menu of the **DITA Maps Manager** view, the resulting documents from the conversion are automatically inserted in the map as follows:

- Actions from **Append child** inserts map nodes as children of the currently selected node.
- Actions from **Insert Before** inserts map nodes as siblings of the currently selected node, above the current node in the map.
- Actions from **Insert After** inserts map nodes as siblings of the currently selected node, below the current node in the map.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the **Batch Documents Converter** add-on:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **Batch Documents Converter** add-on and click **Next**.

4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: A **Batch Documents Converter** submenu will now be available in the **Tools** menu and in the contextual menu. This submenu will contain a list of the various types of available conversions. Selecting one of the types of conversions will open a dialog box where you can configure options for the conversion.

Configuration

Options for configuring the conversions can be found in the preferences page of the add-on (**Options > Preferences > Plugins > Batch Documents Converter**) or in the conversion dialog box.

Conversions from Word (Word Styles Mapping)

The conversions from MS Word work best if you only use the MS Word styles to semantically mark up your document. It is important that sections from the Word document are well defined using the heading styles.

Use the **Word styles mapping** option from the **Batch Documents Converter** preferences page to configure any of the types of Word conversions (Word to HTML, Word to DITA, Word to DocBook4, and Word to DocBook5) by setting a mapping between Word elements and styles to the corresponding HTML element.

If the Word document contains paragraphs formatted with custom styles that are not based on default styles, they have to be set in the Word styles mapping configuration. Those that are not set will be converted into simple paragraphs.

The styles mapping configuration is inherited between styles. If you use a custom style that is based on a default style, the default style mapping configuration will be inherited and also used for the custom style. The mapping from the base style is not inherited if the custom style has a mapping defined in the Word styles mapping configuration.

To define a mapping in the **Word Styles Mapping** table, you can use the already defined default configuration. For example, if you use a custom Word style named `Document Title` that is not based on a default style, you can map this to the HTML "h1" element:

Word element	Word style	HTML elements
p	Document Title	h1:fresh

The resulting 'h1' element will be transformed into the corresponding element when converting to DITA, DocBook 4, and DocBook 5.

The **Word styles mapping** table contains the following columns:

Word element

This column allows one of the following Word elements:

- **p** - Word paragraph
- **r** - Word run
- **b** - bold text
- **i** - italicized text
- **u** - underlined text
- **strike** - strikethrough text
- **table** - table
- **p:unorderd-list(x)** - unordered list (where 'x' is the nesting level of the list)
- **p:orderd-list(x)** - ordered list (where 'x' is the nesting level of the list)

Word style

This column can be used to map a paragraph, run, or table with a specific style (referenced by name).

Styles can also be referenced by style ID. This is the ID used internally in the `.docx` file. To map a paragraph or run with a specific style ID, append a dot followed by the style ID in the **Word element** column (for example: `p.Heading1`).

HTML elements

This column can be used to map the resulting HTML elements. It allows a single element or multiple nested elements.

The nested elements can be declared by using the '>' character (for example: `ul > li`).

The `class` attribute can be specified on the resulting HTML elements by appending a dot followed by the class value, after the element (for example: `p.myClass`).

When converting Word to DITA, these `class` attributes are automatically converted to `outputclass` attributes. This may be useful if you want to apply extra processing on the resulting DITA document using a custom XLS stylesheet.

The `:fresh` syntax can be used to create new elements. If it is not used, the converter will try to reuse the element and close it only when it is necessary.

For example, if the following configuration is set:

p	Heading 1	h1

When the converter finds consecutive Word paragraphs with the style named `Heading 1`, these will be converted into a single `h1` element that contains the text appended from all of the Word paragraphs.

If `h1:fresh` is set in the last column, the converter will create separate `h1` elements.

The `:separator('separator_string')` syntax can be used to specify a separator between paragraphs that are merged when `:fresh` syntax is not specified.

For example, if the following configuration is set:

p	Code Block	pre:separator('\n')

when the converter finds multiple consecutive paragraphs styled with the `Code Block` style, it will merge them into a single `<pre>` HTML element and the "\n" (new line) separator will be used between merged text.

To ignore elements, the '!' character can be added in the **HTML elements** column.

The **Export** button can be used to export the word styles configuration to an XML file. This exported file can be used to configure the MS Word Dynamic Conversion *(on page 3310)* from Oxygen XML Editor by copying the file in the DITA-OT plugin directory: `[OXYGEN_INSTALL_DIR]/frameworks/dita/DITA-OT/plugins/com.oxygenxml.dynamic.resources.converter`.

The **Import** button allows you to import the word styles configuration from an exported XML file.

Note:
The **Word styles mapping** configuration is applied only for the newer version of MS Word files formatted in the Microsoft Office Open XML (DOCX) format.

Maximum Heading Level for Creating Topics

The **Maximum heading level for creating topics** option from the **Batch Documents Converter** preferences page allows you to set a maximum heading level that the converter will process as DITA topics. The headings with a higher level will be converted to `section` elements.

When the output is a DITA topic, this option sets the maximum heading level that will be converted as a nested topic in the document.

When the output is a DITA map, this option sets the maximum heading level that will be extracted as a DITA topic file and referenced in the DITA map hierarchy.

Note:
This option only applies to the HTML to DITA and Word to DITA conversions.

Word to DITA

The **Create DITA maps from Word documents containing multiple headings** option from the conversion dialog box allows you to decide whether the output will be a DITA map or a DITA topic. When this option is selected, the sections from your Word document marked by titles or headings will be separated into individual DITA topics and referenced in a DITA map. If the word document does not contain multiple sections, the output will be a single topic. When this

option is not selected, the output will be a topic with nested topics and sections according to the number of titles and headings from the Word document.

> **Note:**
> Mathematical equations in Word documents should be automatically converted to MathML equations if they are in Office Math Markup Language (OMML) format. If the mathematical equations are in Microsoft Equation Editor format, they first need to be converted to the newer OMML format. See: https://support.microsoft.com/en-us/office/editing-equations-created-using-microsoft-equation-editor-08a44b8c-ae15-41a7-bc15-7239890c0cec.

Markdown to DITA

The **Create DITA maps from Markdown documents containing multiple headings** option from the conversion dialog box allows you to decide whether the output will be a DITA map or a DITA topic. When this option is selected, all headings from your Markdown document will be separated into individual DITA topics and referenced in a DITA map. If the Markdown document does not contain multiple headings, the output will be a single topic. When this option is not selected, the output will be a topic with nested topics or sections according to the number of headings from the document.

The **Create short description elements** option from the conversion dialog box allows you to decide whether or not the `shortdesc` elements are created in the output DITA document. When this option is selected, the first paragraph before the headings from the Markdown document will be converted into DITA short description elements. When this option is not selected, the output will not contain the short description element.

HTML to DITA

The **Create DITA maps from HTML documents containing multiple headings** option from the conversion dialog box allows you to decide whether the output will be a DITA map or a DITA topic. When this option is selected, the headings from your HTML document will be separated into individual DITA topics and referenced in a DITA map. If the HTML document does not contain multiple sections, the output will be a single topic. When this option is not selected, the output will be a topic with nested topics or sections according to the number of headings from the document.

The **Ignore HTML 'div' elements** option from the conversion dialog box allows you to decide whether or not the `<div>` elements will be ignored. When this option is selected, all `<div>` elements will be ignored. When this option is not selected, only `<div>` elements that include the `@class` or `@id` attribute will be handled by the converter.

Confluence to DITA

The **Confluence to DITA** conversion processes the HTML content generated by the Atlassian® Confluence (see https://www.atlassian.com/software/confluence) export process. To export

Confluence content to HTML, log in to your Atlassian® Confluence account and navigate to the specific space that you want to export. Then go to **Space Settings > Export space** and choose to export it as HTML. The resulting `index.html` file must be provided in the **Input files** list from the conversion dialog box.

DocBook to DITA

The **Create DITA maps from DocBook documents containing multiple sections** option from the conversion dialog box allows you to decide whether the output will be a DITA map or a DITA topic. When this option is selected, the sections from your DocBook document will be converted into individual DITA topics and referenced in a DITA map. When this option is not selected, the output will be a single topic with nested topics.

OpenAPI to DITA

The **OpenAPI to DITA** conversion can be used to convert JSON or YAML files that use and conform to the OpenAPI specification (versions 2.0, 3.0, or 3.1) into DITA documents. The **Create DITA maps from OpenAPI documents** option from the conversion dialog box allows you to decide whether the output will be a DITA map or a DITA topic. When this option is selected, the converter will create separate DITA topics for the introduction (including OAS 'Info', 'Server', 'Security Requirement' and 'External Documentation' objects), 'Tag', 'Operation', 'Callback', and 'Components' objects. These topics will be referenced in a DITA map. When this option is not selected, the output will be a single topic with nested topics.

Word to DITA Conversion Notes

The following are some notes about the Word to DITA conversion:

- Paragraphs styled with default Word heading styles (or with custom styles based on default Word heading styles) are handled as topics or sections in the converted DITA output.
- You can choose whether the converted output is a DITA map with referenced topics or a single DITA topic. See the Create DITA maps from Word documents containing multiple headings *(on page 2661)* option.
- You can choose the level of headings that are converted as topics or sections. See the Maximum Heading Level for Creating Topics *(on page 2661)* option.
- You can customize the conversion by adding mappings from your own Word styles to HTML elements. The configured HTML element is converted to the proper DITA element. The `@class` attribute is transformed to the DITA `@outputclass` attribute. See the Conversions from Word (Word Styles Mapping) *(on page 2659)* section.
- Ordered and unordered lists are converted to DITA and the list level is preserved.
- Bold, italic, underline, strikethrough, superscript, and subscript styles are converted to the corresponding DITA elements.
- The formatting of table properties (such as borders) is currently ignored, but the formatting of the text inside the table is treated the same as in the rest of the document. Only the header row formatting is taken into account when converting tables to DITA.
- Footnotes and endnotes are converted.

- Images embedded in Word documents are saved to separate files and referenced in the generated DITA topics.
- Links (cross-references and external links) are converted.
- Line breaks and taken into account.
- Mathematical equations in Word documents are automatically converted to MathML equations if they are in **Office Math Markup Language** (OMML) format. If the mathematical equations are in **Microsoft Equation Editor** format, they first need to be converted to the newer **OMML** format.
- Symbols are converted.
- Index entries are converted.
- The Table of Contents is ignored in the DITA result.

Resources

For more information about the Batch Converter add-on, as well as details regarding other popular add-ons that extend the functionality of Oxygen XML Editor, see the following resources:

DITA Editing

DITA Prolog Updater Add-on

Oxygen XML Editor offers an add-on that contributes a preferences page (**Options > Preferences > Plugins > DITA Prolog Updater**) that includes various options for updating the *prolog* section of a DITA topic or map.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

Note:
If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **DITA Prolog Updater** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **DITA Prolog Updater** preferences page will now be available in **Options > Preferences > Plugins**.

DITA Prolog Updater Preferences Page

The contributed preferences page (**Options > Preferences > Plugins**) includes the following general options:

Author

Specifies the name of the author. By default, it is the system user name.

Date format

Specifies the format of the date that will be added in the prolog section. If the date format entered is invalid, the *yyy/MM/dd* format is used by default.

Limit the number of revised dates to

Specifies the number of revisions that will be kept. Anytime a `<revised>` element is added in the prolog section and the specified limit has been reached, the oldest `<revised>` element is deleted.

Custom *type* attribute value for the original author

Specifies a custom value for the *type* attribute of the `<author>` element that is inserted to emphasize the primary or original author of the content. When is not set, the *creator* value is used.

Custom *type* attribute value for an additional author

Specifies a custom value for the *type* attribute of the `<author>` element that is inserted to emphasize an additional author who is not the primary/original author. When is not set, the *contributor* value is used.

These options are followed by the following options that can be set for DITA topics or maps (or both):

Enable automatic prolog update on save

When this option is selected, the prolog is updated anytime the document is saved.

Set original author

When this option is selected, the primary or original author is set in the prolog when the document is saved. This option is only applicable for new documents.

Set created date

When this option is selected, a *created date* is added to the prolog when the document is saved. This option is only applicable for new documents.

Update additional authors

When this option is selected, an additional author is set in the prolog when the document is saved. This option is only applicable for already existing documents.

Update revised dates

When this option is selected, a *revised date* is added to the prolog when the document is saved. This option is only applicable for already existing documents.

For more information, see the details for this **DITA Prolog Updater** add-on in GitHub.

DITA References View Add-on

Oxygen XML Editor offers an add-on that contributes a **DITA References** side view that shows all outgoing and incoming references for the current DITA topic. Once the add-on is installed, the view is available in both **Text** and **Author** modes.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **DITA References View** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: Once installed, you need to restart Oxygen XML Editor and the **DITA References** view becomes available. To open the view, select  **DITA References** in the **Window > Show View** menu.

Outgoing References

The types of outgoing references that are presented in this view include:

- Image references (referenced with an `@href` or `@keyref` attribute)
- References to other media resources (DITA objects pointing to video, audio, or embeddable frames)
- Cross references (referenced in an `<xref>` element with an `@href` or `@keyref` attribute)
- Key references (referenced with a `@keyref` attribute)
- Content references (referenced with a `@conref` or `@conkeyref` attribute)
- Related links (referenced with an `@href` or `@keyref` attribute)
- Related links defined in relationship tables

This side-view is synchronized with the main editor to make it easy to locate a reference in the current document. It also includes contextual menu actions for opening the target of an outgoing reference or showing its definition location. You can also double-click a reference to open its target.

Incoming References

The **Incoming** references tab shows all references to the current opened DITA topic.

- The references are presented by taking both the **Main Files** support and the current context map configured in the **DITA Maps Manager** view into account.
- The references are grouped into three categories: **Map**, **Cross**, and **Content**.
- To open the target of a reference, you can double-click the references, or press **Enter** with the cursor located on the reference, or right-click the reference and choose **Open reference**.
- To copy the location of the target of the reference, select the reference and press **Ctrl + C** (**Cmd + C** on Mac).
- If a referenced topic is expanded, references to that topic are also displayed.
- While editing a document, if changes appear that might influence how the references were computed, the **Refresh** button can be used to re-compute the references graph and show an updated list of incoming references.

For more information, see the details for the **DITA Outgoing References View** add-on in GitHub.

Resources

For more information about the DITA References add-on, as well as details regarding other popular add-ons that extend the functionality of Oxygen XML Editor, watch the following webinars/presentations:

- Webinar: Add-ons You Can Use for Technical Writing
- Webinar: Extending the Functionality of Oxygen Using Add-ons

Terminology

Terminology Checker Add-on

Oxygen XML Editor offers an add-on that provides support for checking terminology. Once the add-on is installed, you can create a terminology file with a set of rules for each term (or sequence of characters) you want flagged. After referencing the custom file, Oxygen XML Editor will automatically highlight matched terms in the **Author** visual editing mode and offer some contextual menu actions.

Tip:
The terminology checker works for any document opened in the **Author** visual editing mode, including XML file types, and JSON and HTML5 document types.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **Terminology Checker** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Creating Custom Rules for the Terminology Checker

To create your own custom rules for the terminology checker, follow this procedure:

1. Create a terminology file. There is a template available to help you get started in the **New Document** wizard *(on page 377)*. Click the **New** button on the toolbar or select **File > New** and search for the *Terminology File* template. Here is an example of the structure for this type of file:

```
<incorrect-terms lang="en">
    <incorrect-term ignorecase="true">
        <match>Oxygen</match>
        <suggestion></suggestion>
        <message>Product name should be inside a tag.</message>
    </incorrect-term>
</incorrect-terms>
```

2. Save the newly created terminology rules XML file either in a new subfolder named `oxygen-term-checker` located in the current project folder (the current project opened in the application **Project** view), or in a custom folder.
3. If you saved the terminology file in a custom folder path, go to the **Options > Preferences > Plugins > Terminology Checker** preferences page and set the **Additional Terminology folder** path to point to that folder.
4. Click **OK** several times to apply the changes and close the preferences dialog box.

Result: If any of the terms (or sequence of characters) that are defined in the terminology file are detected in any open file, Oxygen XML Editor highlights the matches in the **Author** visual editing mode.

Note:
If you have a folder named `oxygen-term-checker` in the current project that is open in the **Project** view, all the files in that folder will also be loaded by the terminology checker.

Structure of Terminology Rules File

The following elements can be used in the terminology rules XML file:

`<incorrect-terms>`

This is the root element of the XML rules file.

You can specify the `@lang` attribute on the `<incorrect-terms>` root element. When set, the terms defined in this terminology file are applied when the closest `@xml:lang` attribute of the checked node matches the value specified. Not setting this attribute means that the incorrect terms are applied for all nodes.

If the `@xml:lang` attribute is not defined in your document, the language specified in the Spell Check preferences *(on page 238)* is used.

Note:
If the value of the document's `@xml:lang` attribute is not a superset of the value of the `@lang` attribute for the `<incorrect-terms>` element, there will not be a match.

Table 53. Language Matching Matrix

`@lang` value for `<incorrect-terms>` element	`@xml:lang` value	
	en	**en_US**
en	match	match
en_US	not matched	match

You can specify the `@phase` attribute on the `<incorrect-terms>` root element. The value of this attribute is inherited by `<incorrect-term>` children nodes. Not setting this attribute means the default phase is used.

The allowed values are:

- **always** - Incorrect terms are always presented (default value).
- **editing** - Incorrect terms are shown when the document is opened in the **Author** mode.
- **validation** - Incorrect terms are shown when the document is checked from a validation scenario.

For example, set this attribute if you want to apply the most important rules when validating with the *Validate and Check for Completeness* action, while still keeping them applied in the editing window.

`<incorrect-term>`

Defines ways to match and correct an incorrect term. The `<incorrect-term>` element must include a `<match>` element.

The `@ignorecase` attribute specifies whether or not the match is case-sensitive.

The `@severity` attribute can be set to one of the following values: `info`, `warning`, or `error`. Example:

```
<incorrect-term severity="error">
    <match>he</match>
    <message>Pronouns should be avoided.</message>
</incorrect-term>
```

An experimental `@part-of-speech` attribute can be set on the `<incorrect-term>` element with the value set to a part of speech tag (for example: `adjective`, `verb`, etc.) If set, when scanning for terminology problems, the problem is presented only if the term's part of speech matches the one specified. The processor used to identify the part of speech is *Apache OpenNLP* and this feature is supported only for the English language.

Note:
The results may not be 100% accurate, so you should double-check them.

`<match>`

Specify the text fragment to match.

You can specify the `@type` attribute on the `<match>` element, with the values `character`, `whole-word`, or `regular-expression`. The default value is `whole-word`, unless the matched term contains Japanese, Chinese, or Korean characters because Asian languages often do not use spaces to separate words. Example:

```
    <incorrect-term>
        <match type="character">ing</match>
        <message>Progressive tense should not be allowed</message>
    </incorrect-term>
```

`<suggestion>`

The `<suggestion>` element can be left blank or there can be one or more of them inside the `<incorrect-term>` element. It supports regular expressions grouping.

If you want to replace the match with an XML fragment, you can set the `@format` attribute on the `<suggestion>` element with the value `xml`. For example:

```
   <incorrect-term ignorecase="true">
        <match type="whole-word">Oxygen XML Editor</match>
        <suggestion format="xml">&lt;ph keyref=&quot;oxygen&quot;/></suggestion>
        <message>Replace all occurrences of product with key reference.</message>
    </incorrect-term>
```

`<message>`

The `<message>` element is optional. If present, its content is displayed in a tooltip when you hover over a highlight. It supports regular expressions grouping.

`<link>`

The `<link>` element is optional. If present, it provides the source for this rule. Example:

```
<incorrect-term ignorecase="true">
  <match type="whole-word">Oxygen XML Editor</match>
  <suggestion format="xml">&lt;ph keyref=&quot;oxygen&quot;/></suggestion>
  <link>https://www.oxygenxml.com/doc/ug-editor/topics/terminology-checker.html</link>
</incorrect-term>
```

`<xpath-context>`

The `<xpath-context>` element can be used to define simple XPath expressions that match specific elements.

You can specify `@include` and `@exclude` attributes. The elements covered by this simplified XPath will be checked for matches (or the exclusion of a match). A list of comma-separated XPath values can be used. Example:

```
<xpath-context include="p, div, codeblock">
```

The following are examples of how simplified XPath expressions might look like:

- `elementName`
- `//elementName`
- `/elementName1/elementName2/elementName3`
- `//xs:localName`

> **Note:**
> The namespace prefixes (such as `xs`) are treated as part of the element name without taking its binding to a namespace into account.

You can use one or more of the following attribute conditions:

> **Attention:**
> Default attribute values are not taken into account.

- `element[@attr]` - Matches all instances of the specified element when it includes the specified attribute.
- `element[not(@attr)]` - Matches all instances of the specified element when it does not include the specified attribute.
- `element[@attr = 'value']` - Matches all instances of the specified element when it includes the specified attribute with the given value.
- `element[@attr != 'value']` - Matches all instances of the specified element when it includes the specified attribute and its value is different than the one given.

Using Vale Rules with the Terminology Checker

The **Terminology Checker** has partial support for applying custom *Vale* rules.

Supported Vale scopes: **heading**, **table.header**, **table.cell**, **list**, **paragraph**, **code**, **strong**, **emphasis**, **sentence**.

Supported Vale extension points: **Existence**, **Substitution**, **Occurrence**, **Repetition**, **Conditional**.

Result: If any of the terms (or sequence of characters) that are defined in the terminology file are detected in any open file, Oxygen XML Editor highlights the matches in the **Author** visual editing mode.

> **Note:**
> If you have a folder named `oxygen-term-checker` in the current project that is open in the **Project** view, all the files in that folder will also be loaded by the terminology checker. As an example, the Oxygen XML Editor user guide has a folder with some of the Microsoft style guide rules: https://github.com/oxygenxml/userguide/tree/master/DITA/oxygen-term-checker. Once the user guide

project is open in the Oxygen XML Editor **Project** view, the add-on will start using those rules to check the content.

Resources: You can find already created Vale rules that implement various checks on the following websites:

- Vale rules that aim to replicate *Grammarly* checks: https://github.com/testthedocs/Openly/tree/master/Openly.
- Vale rules that aim to automate the *Microsoft* style guide:https://github.com/errata-ai/Microsoft/tree/master/Microsoft.
- Vale rules that aim to automate the *Google* style guide: https://github.com/errata-ai/Google/tree/master/Google.

Working with the Terminology Checker

The **Terminology Checker** side view shows all problems found in the document. You can right-click each problem to apply possible fixes or to find out more details about it. The tooltip for each problem displays a custom message and more information (e.g. for *Vale* rules, it also displays the name of the Vale rule file that defines the rule). You can filter problems based on their severity, match, and message and the toolbar has actions to navigate between problems or to open the **Terminology Checker** preferences page.

You can also right-click problems highlighted in the **Author** visual editing mode to access the following contextual menu actions:

- **Replace with "..."** - Replaces the currently highlighted match with the content inside the `<suggestion>` element.
- **Replace all with "..."** - Replaces all instances of the highlighted match found in the current document with the content inside the `<suggestion>` element.
- **Correct all matching highlights** - Replaces all highlighted matches (all matched terms) within the document with the content inside the first `<suggestion>` element from the terminology file.

The terminology checking can be disabled by clicking the  **Show/Hide Terminology Highlights** toolbar button.

Other Notes:

- The checker automatically skips deleted content with tracked changes and space-preserved elements (e.g. codeblocks).
- When replacements are performed, the capitalization is preserved.
- In the Oxygen XML Editor **Options > Preferences > Plugins > Terminology Checker** page, you can define the highlight colors to be used for each issue depending on its severity. You can also reference a folder that contains the terminology rules. This folder can contain other

folders with terminology files or just the terminology files. The option that controls automatic capitalization can also be found in this preferences page.
- If you select **Project Options** (in the **Terminology Checker** preferences page), the settings are stored in the project file (`.xpr`) that can be shared with other users *(on page 322)*.

Terminology Checker Preferences

The **Options > Preferences > Plugins > Terminology Checker** preferences page contains various settings for configuring tool. The preferences page can be saved at project level to share these settings, as is common for a group of users who use the same project configuration.

Highlight background

You can specify various colors to influence the background colors for terminology highlights that are added in the **Author** visual editing mode.

Highlight decoration

You can specify various colors to influence the highlight decoration styles for terminology highlights that are added in the **Author** visual editing mode.

Editing

Preserve case when performing replacements

Controls whether or not the original letter casing is automatically preserved when replacing words. The option is selected by default.

Report unsupported Vale rules as errors

If selected (default), errors that are related to Vale terms (such as unsupported extension points or invalid properties) are reported. If not selected, unsupported Vale rules are ignored (although an error is still reported if the file is invalid).

Learned terms

Default project terminology folder

Displays the default location where all the terminology rule files (XML or Vale) are stored. By default, the rule files located in the `oxygen-term-checker` subfolder of the current project folder (the current project loaded in the **Project** view) are automatically loaded and used.

Additional terminology folder

You can use this option to specify an additional terminology folder where XML and Vale rule files are located. You can use editor variables such as `${pd}/terms` to specify the path to the terminology folder.

Checking Multiple Resources

Once installed, the terminology checker add-on can be used to batch-check multiple files:

- Right-click on the root of the DITA map opened in the **DITA Maps Manager** view and choose **Check terminology**.
- Right-click a folder in the **Project** view and choose **Check terminology**.
- Create a new validation scenario or edit an existing validation scenario, and add a new validation stage. For the **File type** field, choose **XML Document** and for the **Validation engine** field, choose **Terminology checker**. The validation scenario can be used in multiple ways:
  - In the **Project** view, you can right-click a folder and validate using a specific validation scenario.
  - In the **DITA Maps Manager** view, you can use the **Validate and Check for Completeness** toolbar action and choose to **Batch validate referenced DITA resources**. This will apply the associated validation scenario for each topic or map referenced in the context of the main DITA map.

Terminology Files Contributed from Other Oxygen Add-ons

Any **Oxygen** add-on can contribute terminology files that will be used by the Terminology Checker. The contributed terminology files will be loaded and used if the contributor add-on is enabled.

The following pre-conditions must be fulfilled:

1. The contributor add-on's `plugin.xml` descriptor file should reference the rules folder in the `plugin.xml` as a `librariesFolder` with a `global` scope:

```
<plugin
    id="unique.identifier.name"
    name="My Style Guide"
    description="Style Guide"
    version="1.0"
    vendor="Vendor Name"
    class="ro.sync.exml.plugin.Plugin"
    classLoaderType="preferReferencedResources">
    <runtime>
        <librariesFolder name="Rules_Folder" scope="global"/>
    </runtime>
</plugin>
```

2. The contributor add-on should have a marker file named `oxy-terms-auto-detect` inside the rules folder. The terminology files can be added in the rules folder or organized in subfolders (the Terminology Checker scans the subfolders to identify the terminology files). Inside the `oxy-terms-auto-detect` file, there should be a textual description of the terminology file contents, which is used when presenting add-on contributed terms in the Terminology Checker preferences page (**Options > Preferences > Plugins > Terminology Checker**).

ASD Simplified Technical English Specification (ASD-STE100) Rules

An extra add-on is available that contributes *ASD Simplified Technical English Specification* rules to the **Terminology Checker**. It contains technical rules based on ASD-STE100 (http://www.asd-ste100.org), but note that these rules are not endorsed by ASD-STE100.

To install these rules, use the manual add-on install procedure *(on page 2668)* and select **ASD Simplified Technical English Specification (ASD-STE100) Writing Style Guide Rules (experimental)** for the add-on to install.

MS Writing Style Guide Vale Rules

An extra add-on is available that contributes a set of rules based on the *Microsoft Writing Style Guide* to the **Terminology Checker**. It contains a Vale-compatible (https://vale.sh) implementation of the MS Writing Style Guide (https://learn.microsoft.com/en-us/style-guide/welcome/) as provided by the *errata-ai* open-source project (https://github.com/errata-ai/Microsoft). Note that this project is neither maintained nor endorsed by *Microsoft*.

To install these rules, use the manual add-on install procedure *(on page 2668)* and select **MS Writing Style Guide Vale Rules** for the add-on to install.

Resources

For more information about the Terminology Checker add-on, along with details regarding other popular add-ons that extend the functionality of Oxygen XML Editor, watch the following webinar:

- Webinar: Add-ons You Can Use for Technical Writing

Vale Linter for Markdown and HTML Validation Add-on

The Vale Validation add-on runs the Vale linter over the currently edited file and presents the validation errors in the results area at the bottom of the application. A *Linter* is a tool that automatically verifies specific rules against your code or documentation. This is useful for enforcing a style guide or for catching commonly mistaken branding issues.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install this add-on, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

> **Note:**
> If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **Vale Linter for Markdown and HTML Validation** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Setup the Oxygen Vale Validation

To set up the Vale validation, follow this procedure:

1. Download and unzip the proper Vale executable for your OS. On Linux and macOS, you must give executable permission to the Vale executable. You can do this by opening a console in the Vale directory and running:

   ```
   chmod u+x vale
   ```

2. Go to **Options > Preferences > Plugins > Oxygen Vale Validation** and specify the path to the previously downloaded Vale executable.
3. In the same preferences page, you can also specify a path to a Vale configuration file (`.vale.ini`). Vale automatically detects this file by looking 6 levels up in the current file's ancestor directories, but you can also impose one.

Vale Styles

Vale uses collections of individual YAML files (or "rules") to enforce particular writing constructs. These collections are referred to as *styles* and are organized in a nested folder structure at a user-specified location. The `.vale.ini` file is where you will control most of Vale's behavior, including which files to lint and how to lint them. Vale automatically detects `.vale.ini`, but you can also specify the path to `.vale.ini` from the plugin's preferences page (**Options > Preferences > Plugins > Oxygen Vale Validation**).

Third-party Styles

Vale has a growing selection of pre-made styles available for download from its style library.

Validation

After setting up the Vale executable, creating or downloading Vale styles, and specifying the path to `.vale.ini`, the add-on will intercept the and Manual Validation and contribute errors and warning obtained by running Vale validation over the current file. The errors and warnings are highlighted in the editor.

Note:
Although Vale supports multiple file formats, the Vale Validation add-on currently only supports Markdown (*.md files) and HTML files.

Translation

Fluenta DITA Translation Add-on

Introduction

Fluenta is a tool designed to simplify the translation of DITA projects. It parses a DITA map, resolves the references to all topics and subtopics, and prepares a unified XLIFF file that you can send to your *Language Service Provider*. The **Fluenta DITA Translation** add-on allows you to manage the Fluenta translation workflow directly from within Oxygen XML Editor.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

2. Select the **Fluenta Dita Translation** add-on and click **Next**.
3. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
4. Restart the application.

Result: A **Fluenta**submenu is now available in the DITA Maps Manager's *(on page 3073)* contextual menu.

Translation Workflow

A translation workflow based on Fluenta has the following steps:

1. Create a Fluenta project *(on page 2679)*. A project contains metadata associated with a DITA map (for example, the languages that the project is translated into). This is a one-time action.
2. At various milestones (for example, when a new version is released), you generate XLIFF files *(on page 2680)* for each language you translate to.
3. You send the XLIFF file to the translation service provider.
4. Once the XLIFF returns from translation, you import the XLIFF file *(on page 2680)*. A translated version of your map and topics will be generated at the selected location from the XLIFF file.

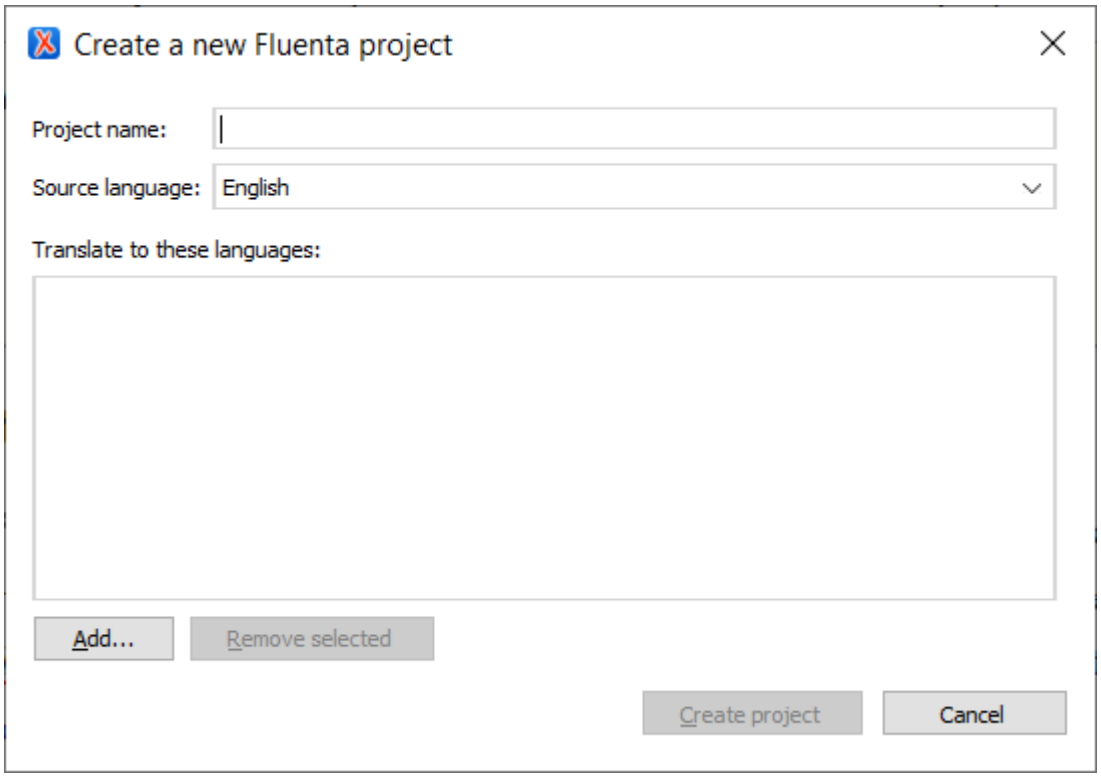
Creating a Fluenta Project

The first step in the workflow is to create a Fluenta project:

1. Open the main DITA map in the DITA Maps Manager *(on page 3073)*.
2. Right-click the map and select **Fluenta > Create project**.

   Note:
   This action is visible only if there is no project detected for the open DITA map.

3. In the resulting dialog box, you need to provide a name for the project and the languages that the project will be translated into.



Result: A translation memory *(on page 2682)* with the same name as the project will automatically be created. Also, only one project can be created for a DITA map file. Once created, you will be able to edit it to change certain information.

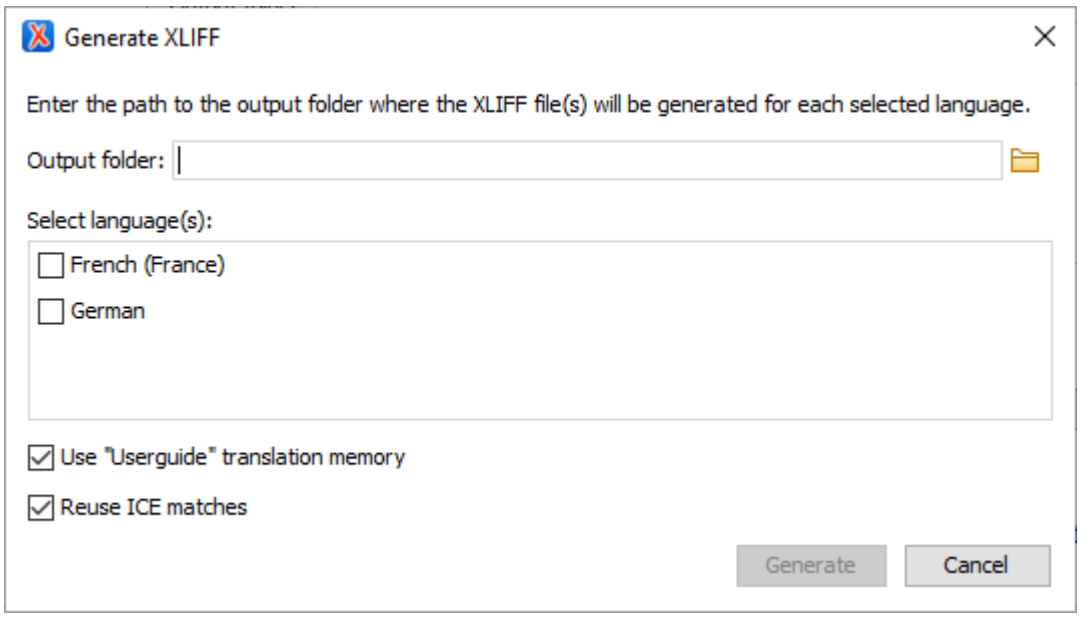
Generating XLIFF Files

When you are ready to send the project to translators, you can generate an XLIFF file like this:

1. Open the main DITA map in the DITA Maps Manager *(on page 3073)*.
2. Right-click the map and select **Fluenta > Generate XLIFF**.

   > **Note:**
   > This action is visible only if there is a Fluenta project *(on page 2679)* associated with the current DITA map and the XLIFF files will be generated for this project.

3. In the resulting dialog box, select the output folder where the XLIFF file(s) will be generated and the languages that you want to send to translation.



4. Selecting the **Use translation memory** option will use the translation memory associated with the project to recover translations for the segments not yet translated. Selecting the **Reuse ICE matches** option will compare current content with the content translated in the past and reuse all existing translations.

Result: An XLIFF file will be generated in the output folder for each selected language.

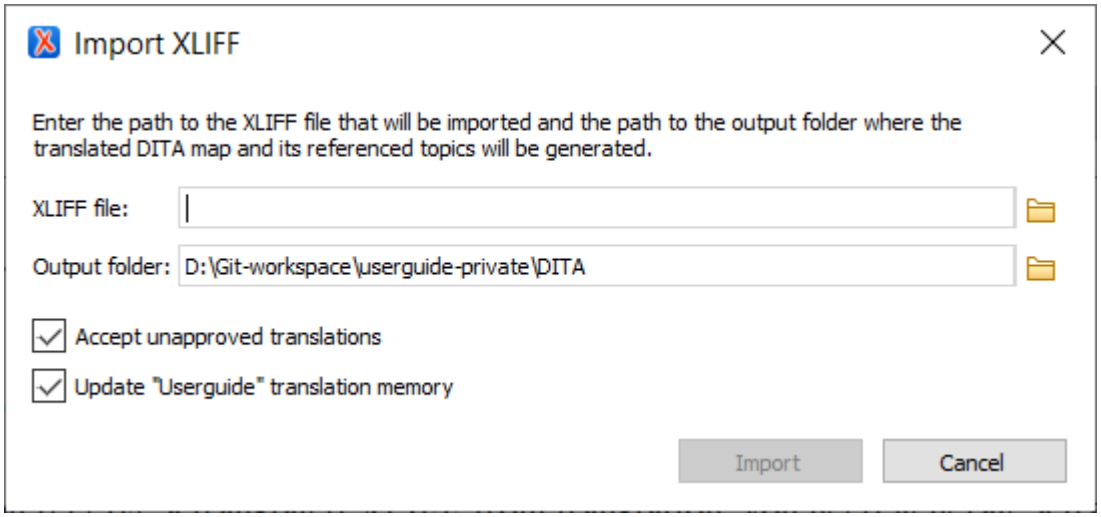
Importing XLIFF

Once you receive a translated XLIFF from translation, you need to generate a translated version of your project:

1. Open the main DITA map in the DITA Maps Manager *(on page 3073)*.
2. Right-click the map and select **Fluenta > Import XLIFF**.

Note:
This action is visible only if there is a Fluenta project *(on page 2679)* associated with the current DITA map and the XLIFF file will be imported for this project.

3. In the resulting dialog box, browse for the XLIFF file:



4. Selecting the **Accept unapproved translations** option will use translations that are not marked as approved in the XLIFF file being imported. Selecting the **Update "{MemoryName}" translation memory** option will store the imported translations in the project translations memory.

Result: A translated version of the project content will be created in the indicated output folder.

CAUTION:
If your images are not in SVG format, you will have to copy them to the newly generated project.

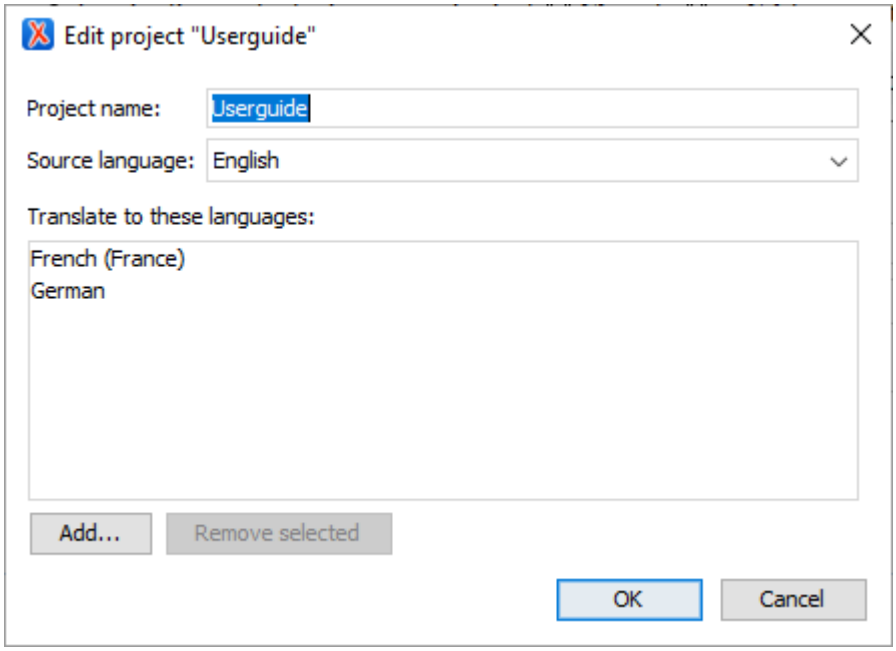
Editing a Fluenta Project

Sometimes after creating a project, certain information needs to be edited. The steps are similar to those for creating a new project:

1. Open the main DITA map in the DITA Maps Manager *(on page 3073)*.
2. Right-click the map and select **Fluenta > Edit project "{ProjectName}"**.

Note:
This action is visible only if there is a Fluenta project *(on page 2679)* associated with the current DITA map and this project will be edited.

3. In the resulting dialog box, you need to replace the project information you want updated.

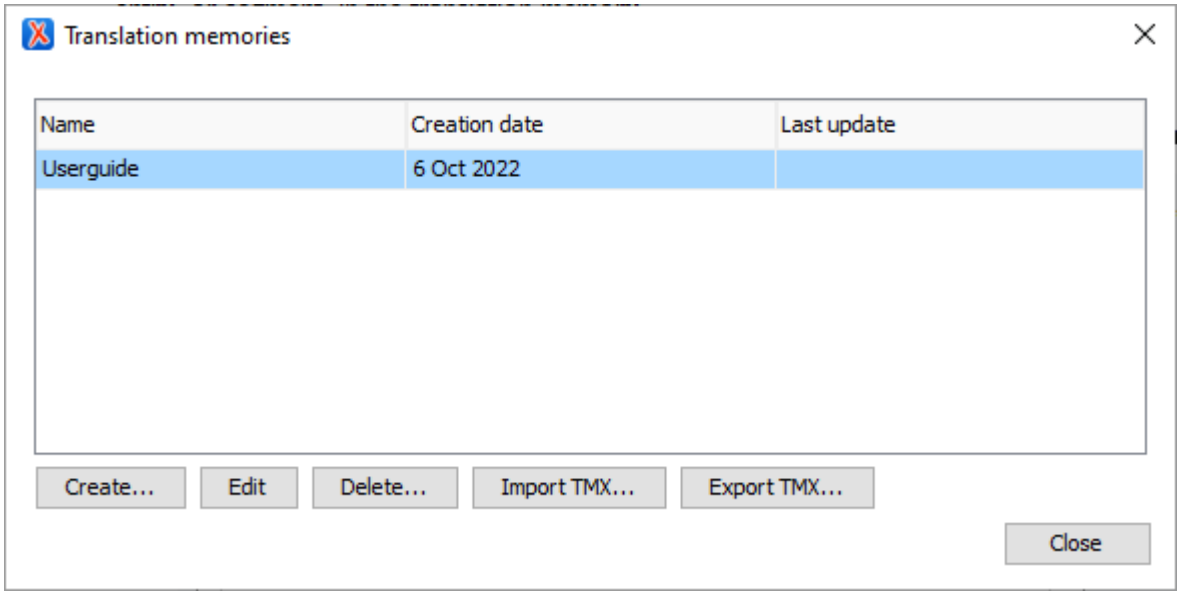


Important:
It is not recommended to edit the name of a project or its source language because they may become inconsistent with the associated translation memory.

Managing Translation Memories

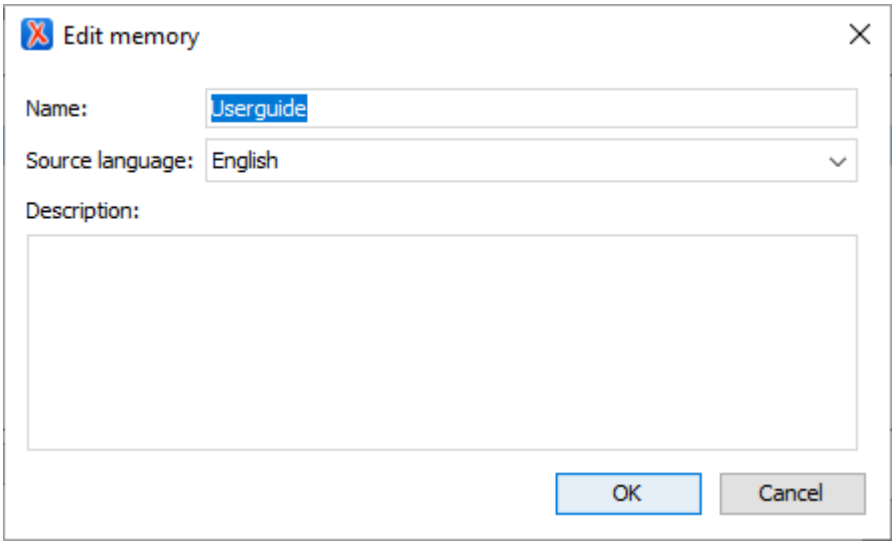
A translation memory is a database that stores sentences, paragraphs, or segments of text that have previously been translated. The original language (sometimes referred to as the "source") and its translation (also referred to as the "target") are both included in each entry or segment in the translation memory.

1. Open the main DITA map in the DITA Maps Manager *(on page 3073)*.
2. Invoke the contextual menu and select **Fluenta > Manage translation memories**.
3. In the resulting dialog box, you will see a table with all the translation memories defined in Fluenta.



4. In this dialog box, you can perform the following operations:
   - **Create** - This action will open a dialog box for creating a new translation memory.

   - **Edit** - This action will open a dialog box for editing the selected translation memory from the translation memories table.



- **Delete** - Deletes the selected translation memory. If a translation memory is associated with a project, it cannot be deleted.
- **Import TMX** - Populates the content of the translation memory with content from a specified import file.

  Note:
  One or more files can be imported into a translation memory.

- **Export TMX** - Exports the selected translation memory to TMX format to view its content and use at a latter time.

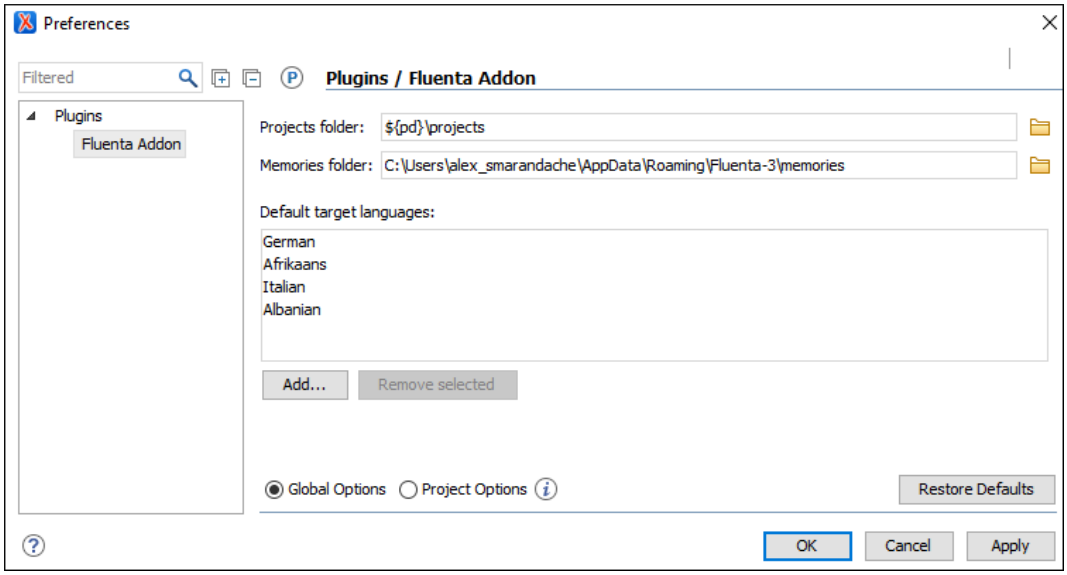
Preferences

Various options can be configured in the preferences page, both at the global level and at the project level.

1. Open the main DITA map in the DITA Maps Manager *(on page 3073)*.
2. Right-click and select **Fluenta > Preferences**.

   Result: In the resulting dialog box, you will see the **Fluenta Addon** preferences page:

Figure 626. Fluenta Addon Preferences Page



3. Configure options as needed. You can set the folders where projects and translation memories will be saved. Both absolute paths and paths that contain editor variables can be used. Also, you can set some target languages that will be pre-filled when a Fluenta project is created.

Translator Helper Add-on

Oxygen XML Editor offers an add-on that provides support for helping translators. Once the add-on is installed, you can use Google Translate to create a preliminary translation for your XML content that can later be manually improved. The add-on is also useful for showing potential customers how a DITA project will look like after it is translated into their native language. After the add-on is installed, a **Translator Helper** view is available from the **Window > Show View** menu.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field.

   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **Translator Helper** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart Oxygen XML Editor.

Result: The **Translator Helper** view now be available and can be selected from the **Window > Show View** menu.

Features:

- You can translate content to various languages using *Google Translate* or *DeepL Translator*:
  1. In Oxygen XML Editor, select the content you want to translate in **Author** mode. You can also select the entire contents of the document.
  2. Right-click, select **Translate**, and choose the target translator and language.
  3. Copy the translated content from the resulting web page (the easiest way to do this is to use the **Copy translation** button for *Google Translate* or the **Copy to clipboard** button for *DeepL Translator*).
  4. Go back to Oxygen XML Editor. If your original selection included multiple inline elements (or entire block elements or the entire document), a dialog box will be displayed. Click the **Replace** button to replace the selection with the copied translated content. If you leave the **Show original content side-by-side** option selected, the original untranslated content will be displayed in the **Translator Helper** side view.
- You can choose to display your original content in a **Translator Helper** side view so that you can see the original untranslated content side-by-side with the content that you are editing/translating. To open this side view, right-click anywhere in the **Author** mode editor pane and select the **Original Content Side By Side** action (or select **Window > Show View > Translator Helper**).

DITA Translation Package Builder Add-on

Oxygen XML Editor offers an add-on that contributes contextual menu actions that help you build a translation package for DITA files that can be sent to translators. You can also extract the changed files back into your project once you receive the package back from the translators.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.
3. Select the **DITA Translation Package Builder** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: A **Translation Package Builder** submenu will now be available in the contextual menu of the **DITA Maps Manager**. This submenu includes actions to generate a ZIP package of modified files that can be sent to translators, as well as an action to extract translated files back into your DITA project.

For more information, see the details for this **Translation Package Builder** add-on in GitHub.

Using the Translation Package Builder

Once the add-on is installed, a sub-menu named **Translation Package Builder** is available in contextual menu of the **DITA Maps Manager** with the following actions:

- **Generate Milestone** - Use this action first. It generates a unique hash for each documentation resource. This information is used by the second action (**Create Modified Files Package**) to detect which files have been modified. A milestone file should be generated after you install this add-on and then again after each package is sent to translators.

- **Create Modified Files Package** - This action detects which files have been changed since the last generated milestone. These files are packed inside a ZIP file that can be sent to translators. After doing this, you can also generate a new milestone so that the next package will only contain new changes.
- **Apply Package** - When the translated files arrive from the translator, you should open the DITA map that corresponds to the received language (e.g. open `dita-map-french.ditamap` if the package contains the french translation). Invoking this action will extract the changed files inside the map's directory.

Productivity

Oxygen AI Positron Assistant

The **Oxygen AI Positron Assistant** add-on uses the advanced **Oxygen AI Positron** service to support technical documentation writers throughout their content creation process.

https://www.youtube.com/embed/Do_KWYZfCFg?si=2Mrm7Bh1pmPvehqV

Overview

In a simplified form, technical documentation is often done in two stages: analysis and implementation. In the analysis stage, technical writers could use various resources such as web searches, ChatGPT, or discussions with colleagues or engineers to further understand the subject that needs to be documented. In the second stage, technical writers would use tools such as Oxygen XML Editor to write the actual content.

The **Oxygen AI Positron Assistant** add-on provides various ways to use AI services (such as ChatGPT) to help writers while editing or reviewing the technical documentation. For example, it can be used to receive hints about what to write next, improve the readability of content, or re-structure the content in various ways.

Note:
Content received from the **OpenAI ChatGPT** model may be inaccurate or contain misleading information, so it needs to be thoroughly reviewed and revised accordingly.

Terms:
The terms of use for the service can be found here.

AI Positron Assistant Samples Playground.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install this add-on, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

2. Select the **Oxygen AI Positron Assistant** add-on and click **Next**.

   > **Important:**
   > There are two different iterations of the add-on and you can only have one or the other installed at once:
   > - **Oxygen AI Positron Assistant** - The regular version of the add-on.
   > - **Oxygen AI Positron Assistant (Enterprise)** - This Enterprise version is for those who want to connect to their own OpenAI or MS Azure OpenAI account.

3. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
4. Restart the application.

Result: The **AI Positron Assistant** side view is now available.

Connecting to the Oxygen AI Positron Service

You can use the **AI Positron Assistant** side view to easily configure login details and connect to the `Oxygen Positron Service` in the web browser.

To initiate the connection process, use the **Connect** button in the **AI Positron Assistant** view (or from the user drop-down menu at the top-right corner of the view).

Note:
By default, the `Oxygen Positron Service` uses the OpenAI ChatGPT server version `3.5` API to propose document generation and change suggestions. The used model can be changed to a more advanced model (for example, GPT 4) in the AI Service Configuration Preferences Page *(on page 2698)*.

AI Server Requests and Credits

Each user has a limit to the number of requests that are sent to the AI server each month and this is managed through the use of credits.

Important:
To use your own company-specific AI service, the specific Oxygen AI Positron Assistant Enterprise *(on page 2702)* add-on needs to be installed instead of the one listed above.

Accessing AI-Powered Actions

Once you log in to the server, a variety of AI actions are available in:

- The **Actions** drop-down menu at the top of the **AI Positron Assistant** side view *(on page 2692)*.
- The main chat panel when a conversation has not yet started.
- The **AI Positron Assistant** submenu that is available in the contextual menu when right-clicking in the main editor.
- The **AI** main menu at the top of the application.

In addition, when moving the cursor within the document, a *quick assist* bulb (💡) appears in the navigation vertical stripe bar. Clicking the bulb opens a popup with actions such as **Correct Grammar**, **Improve Readability**, or **Use Active Voice** that are invoked in the context of the closest paragraph that contains the cursor.

The progress and results of triggering an action are displayed in the **main chat** pane *(on page 2692)*.

Built-in AI Actions

Accessibility

- **Generate Image Alternate Text** - Generates an alternate text for a DITA XML image that is selected in the main editing area in the Author visual editing mode.

Content Generation

- **Generate Documentation Draft** - Generates a documentation draft of a DITA XML topic based on a configuration file that fine tunes the generation process by specifying the context, audience, summary, instructions, images, and a similar topic to help the AI generate the draft content.

- **New DITA Topic** - Generates a DITA XML topic based on a text description entered in a popup dialog box.
- **Update Content Based on Images** - Updates the content of a DITA XML topic based on the images that it references.
- **Continue Writing** - Generates additional text based on the content preceding the cursor position.
- **Short Description** - Generates a short description (inside a `<shortdesc>` element) based on a summary of the selected text (or the entire document if there is no selection). You can configure the style and the approximate number of sentences to be generated.
- **Index Terms** - Generates a `<keywords>` element that contains index terms obtained from the selected text (or the entire document if there is no selection).
- **Follow Instructions (available for XSLT, Schematron, XSD, CSS, XQuery, JSON, and JSON Schema)** - Replaces the selected instructions with content generated based on them.

Development

- **Explain Code (available for XSLT, Schematron, XSD, CSS, XQuery, JSON, and JSON Schema)** - Generates an explanation of the code found in the current selection or the code at the current cursor location (or the whole document).
- **Chat About Code (available for XSLT, Schematron, XSD, CSS, XQuery, JSON, and JSON Schema)** - Creates a new chat to start a discussion with the AI regarding the code found in the current selection or the code at the current cursor location (or the whole document).
- **Document Code (available for XSLT, XSD, and Schematron)** - Generates the documentation for the selected content, current node, or entire document. It inserts the documentation as an XML comment before the documented code.
- **Generate Code (available for XSLT, Schematron, XSD, CSS, XQuery, JSON, and JSON Schema)** - Generates the code for the current editor type (text/xsl, text/xquery, text/css, text/json, text/xsd, text/sch) based on the instruction specified in the selected text from the editor or in the comment preceding the cursor location.

Rewrite

- **Correct Grammar** - Generates a suggestion for correcting the grammar and spelling within the selected content.
- **Improve Readability** - Modifies the selected content to improve readability and fix grammar/spelling errors. If you hover the mouse prompt over this button, a **Settings** button becomes available in the top-right corner. Clicking the **Settings** button opens a pop-up window where you can choose the writing level of the content to be generated. You can choose between: **5th grade (Very Easy)**, **8th grade (Plain English)**, and **College (Advanced)**.

- **Use Active Voice** - Generates a suggestion for replacing the selected content with content that has been converted from passive to active voice.
- **Itemize** - Generates a suggestion for converting the selected content into a list of items.
- **Join Items** - Generates a suggestion for converting the selected list of items into a paragraph.

Overview

- **Answer Questions** - Generates answers to questions that the AI finds within the selected content (or the entire document if there is no selection).
- **Generate Questions** - Generates a list of five questions that are answered within the selected content (or the entire document if there is no selection).
- **Summarize** - Generates a summary of the selected content (or the entire document if there is no selection).
- **Readability** - Generates suggestions for changing the selected content (or the entire document if there is no selection) to improve its general readability.

Translation

- **English**, **French**, **German**, **Japanese** - These actions translate the selected text to the target language, while preserving the original XML markup.
- **Other...** - This action behaves like the previous ones, but it allows you to provide the target language. You can either choose from the predefined values or type another one.

Marketing

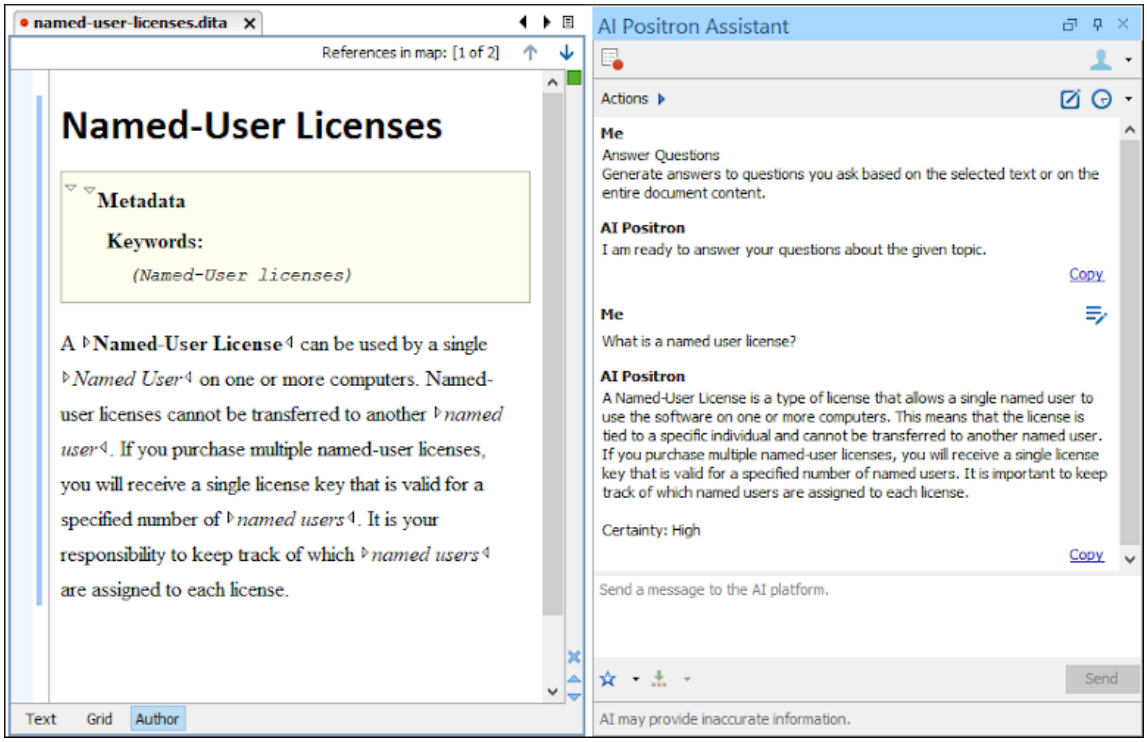
- **Release Notes** - Creates release notes based on a set of features or issue ticket numbers with optional descriptions.
- **Marketing Post** - Creates a marketing post based on a list of ideas or release notes.
- **Improve SEO** - Rewrites the content to enhance search engine optimization.
- **Pain-Agitate-Solution** - Rewrites the content using a marketing style based on the *Pain-Agitate-Solution* framework.
- **Features-Advantages-Benefits** - Rewrites the content using a marketing style based on the *Features-Advantages-Benefits* framework.

Tip:
Custom actions can be configured in the AI Positron Assistant preferences page *(on page 2697)*.

AI Positron Assistant View

The add-on provides access to the **AI Positron Assistant** side-view. If the view is not displayed, it can be opened by selecting it from **Window > Show View**.

Figure 627. AI Positron Assistant View



The **Actions** drop-down menu at the top of the **AI Positron Assistant** view contains the available AI-powered actions that can be used to generate and refine content *(on page 2690)*. Simply select the action to trigger it. You can hover the mouse cursor over an action to see a description of what the action does. A set of 5 recently used actions are also available in the **Actions** drop-down menu.

The **Record** button in the top-left corner of the view allows you to create custom actions or prompts by recording changes *(on page 2699)*.

There is also a user drop-down menu at the top-right corner of the **AI Positron Assistant** view that contains the following:

- **My account** - Opens a webpage where you can see your current subscription package and credit status.
- **Disconnect** - Disconnects **Oxygen** from the `Oxygen Positron Service`.
- **Preferences** - Opens the **Oxygen AI Positron Assistant** preferences page *(on page 2697)* where you can configure the **AI Positron service address** and provide a **Context** for the user that the AI will use to create more relevant and personalized responses.

The main chat pane presents the results after processing an action and allows you to further refine the responses by sending messages to the **Positron** service platform. When an AI Positron action is triggered, the chat pane displays the progress and results.

You can also start chatting directly, without invoking an action. In this case, if there is content selected in the main editor area when a chat is initiated, the selection is passed to the AI as context for the conversation.

The response is received from the server in streaming mode (the AI sends chunks of the response as it is being generated rather than waiting to send the entire response after it is generated).

Note:
When working with Oxygen XML Editor versions 27 and newer, after the entire response is received, if it contains well-formed XML content and the current document is in the **Author** visual editing mode, the response is presented in a visual manner by default, without showing the XML tags. A small toggle button located in the response area allows you to choose between visual or plain XML text for the presentation of the response.

Once the entire response is received from the server, the following actions are available under the response:

- **Insert/Replace** - Inserts the response at the cursor location within the document (or replaces the selected content).
- **Preview** - Allows you to preview the content that would be inserted at the cursor location within the document.
- **Copy** - Copies the response to the system clipboard.

Tip:
You can also partially select content from the response area, then right-click to open the contextual menu, and use the **Insert/Replace**, **Preview**, or **Copy** actions on that partially selected content.

The Chat **History** drop-down toolbar button makes it easy to go back to previous conversations and continue them.

You can use the bottom pane to refine the response by sending a message to the AI platform and it will generate a new response based upon your message. You can create your own favorite prompts and use supported variables to specify the content that is sent to the platform. You can use the **Favorites** drop-down button to store a favorite prompt. You can use the **Insert Variables** drop-down button to select one of the supported variables:

- **${selection}** - Expands to the currently selected content.
- **${selection-original}** - Expands to the currently selected content. If the current selected content contains track changes, they are rejected, resulting in the original version of the text.
- **${selection-final}** - Expands to the currently selected content. If the current selected content contains track changes, they are accepted, resulting in the final version of the text.
- **${document}** - Expands to the content of the entire document.
- **${attach(`filePath`)}** - Attaches a specified image (in `png` or `jpeg` format) or an XML or text file to the conversation. You can also attach files in an easier way by using the dedicated **Attach** action.

Tip:
Previously sent prompts can be modified directly in the chat thread. Once a prompt is edited, a new chat thread is started based on the new prompt's content. For edited prompts, you can use the **Next**/**Previous** buttons to navigate between chat threads.

To clear the information in the chat pane and start a new chat, click the **New Chat** button in the top-right corner of the view.

Generating Documentation Drafts

The **AI Positron Assistant** add-on provides the ability to generate a documentation draft of a DITA topic based on a configuration file that tailors the draft generation process using a context, instructions, images, and other data.

Once the add-on is installed, you can use the **New Document** wizard *(on page 377)* to create a new **AI Doc Draft Configuration** file, that can be edited in **Author** mode. Validation and content completion are automatically provided for such configuration files. The **Author** mode also renders short explanations for each element, as well as buttons for inserting the optional elements.

After providing the configuration data, you can use the **Generate Documentation Draft** action to trigger the AI-based drafting process. Once the AI response is complete in the **AI Positron Assistant** side-view, click the **Create document** link to create a new DITA topic with content generated based upon the data in the configuration file.

Notice:
Only PNG, JPEG, and non-animated GIF images should be provided in the configuration file.

The simplest form of the configuration file would only contain the title and summary that will be used by the AI as a starting point:

```
<?xml version="1.0" encoding="UTF-8"?>
<doc-draft>
  <title>Generate Documentation Draft</title>
  <instructions>
    <draft-summary>The new "Generate Documentation Draft" action was added to the
"Content Generation" category and can be used to draft a DITA documentation topic
using AI and a configuration file.</draft-summary>
  </instructions>
</doc-draft>
```

Other data elements can be used to further configure the drafting process, such as the *context*, *target audience*, *instructions*, *images*, and a *similar topic*.

```
<?xml version="1.0" encoding="UTF-8"?>
<doc-draft>
  <title>Generate Documentation Draft</title>
  <context>I am working on the user manual of a software application called Oxygen XML Editor,
 used for authoring and publishing XML content.</context>
  <prolog>
    <metadata>
```

```
      <audience>The audience of our user manual is very wide and includes
people without a technical background.</audience>
    </metadata>
  </prolog>
  <instructions>
    <draft-summary>We have a new action in the contextual menu of the Project side-view,
 called "Format and Indent...",
 that can be used to pretty print multiple files at once. The action is available in both
the Oxygen XML Editor stand-alone distribution and the Eclipse plug-in.</draft-summary>
    <instruction>Analyze the following image and document the dialog box
 and all its components.</instruction>
    <image href="format-and-indent-files.png"/>
    <instruction>Also add a DITA "note" element that mentions the fact that this feature
is not available for XQuery files.</instruction>
  </instructions>
  <relationship-context>
    <similar-topic href="spell-check-in-files.dita"/>
  </relationship-context>
</doc-draft>
```

AI Refactoring

The **AI Positron Assistant** add-on contributes an **AI Positron XML Refactoring** action in the contextual menu (**Refactoring > AI Positron XML Refactoring**) of both the **Project** and **DITA Maps Manager** views in Oxygen XML Editor. It can be used to refactor multiple XML files (local or remote) at once.

You can invoke the **AI Positron XML Refactoring** action to apply either a predefined AI action or a custom prompt to modify the selected XML resources. The resulting **AI Positron XML Refactoring** dialog box presents an estimate of the amount of credits that will be consumed by the operation, and you have the option to preview the changes before applying them over the original content.

For example, you could use the predefined **Translate to** action to translate multiple DITA topics into a certain language or apply the **Correct Grammar** or **Improve Readability** actions on multiple resources.

XML Refactoring

The add-on contributes AI-specific XML refactoring actions in the XML Refactoring tool's wizard (**Tools > XML Refactoring**, in the **AI** category):

- **Generate alternate text for images in DITA XML topics** - Generates an alternate text for images in DITA XML topics.
- **Generate missing short descriptions in DITA XML topics** - Generates a short description (inside a `<shortdesc>` element) for DITA XML topics.
- **Shorten existing short descriptions in DITA XML topics** - Generates a shorter version of an existing short description for DITA XML topics.

The XML refactoring actions can be applied on multiple resources and are based on the `ai:transform-content` and `ai:verify-content` XPath extension functions contributed by the add-on.

Oxygen AI Positron Assistant Preferences Page

Various settings can be configured in **Options > Preferences > Plugins > Oxygen AI Positron Assistant**:

Context

The context provides useful information about the user to the AI and is used in each action and chat request to create more relevant and personalized responses.

Actions section

Load default actions

Specifies if default actions are loaded.

Additional actions folder

You can use this option to specify a local folder where you have stored additional actions.

Actions to exclude

You can specify a comma-separated list of IDs for the actions that you do not want presented in the list of available actions. Use the menu to the right of the text field to choose the actions to exclude.

XPath Functions section

Enable XPath Functions

Enables the use of AI-specific XPath functions in Oxygen XML Editor when applying Schematron validation or XSLT transformations. This feature is disabled by default.

Cache responses and reuse them for identical prompts

If enabled (default), responses for identical requests are stored (cached), resulting in fewer requests being sent to the AI server and faster completion times. A **Clear cache** button located to the right of this option can be used to clear the cache.

Cache size

Specifies a maximum limit for the cache size.

Notify me when the number of requests exceeds

You can select this option and specify a number of AI requests that when exceeded, a confirmation dialog box is displayed asking if you want to continue using the XPath AI functions. If you select "No" for the answer, the XPath functions will be disabled.

AI Service Configuration Preferences Page

Various service-related connection settings can be configured in **Options > Preferences > Plugins > Oxygen AI Positron Assistant > AI Service Configuration**:

AI Positron Service address

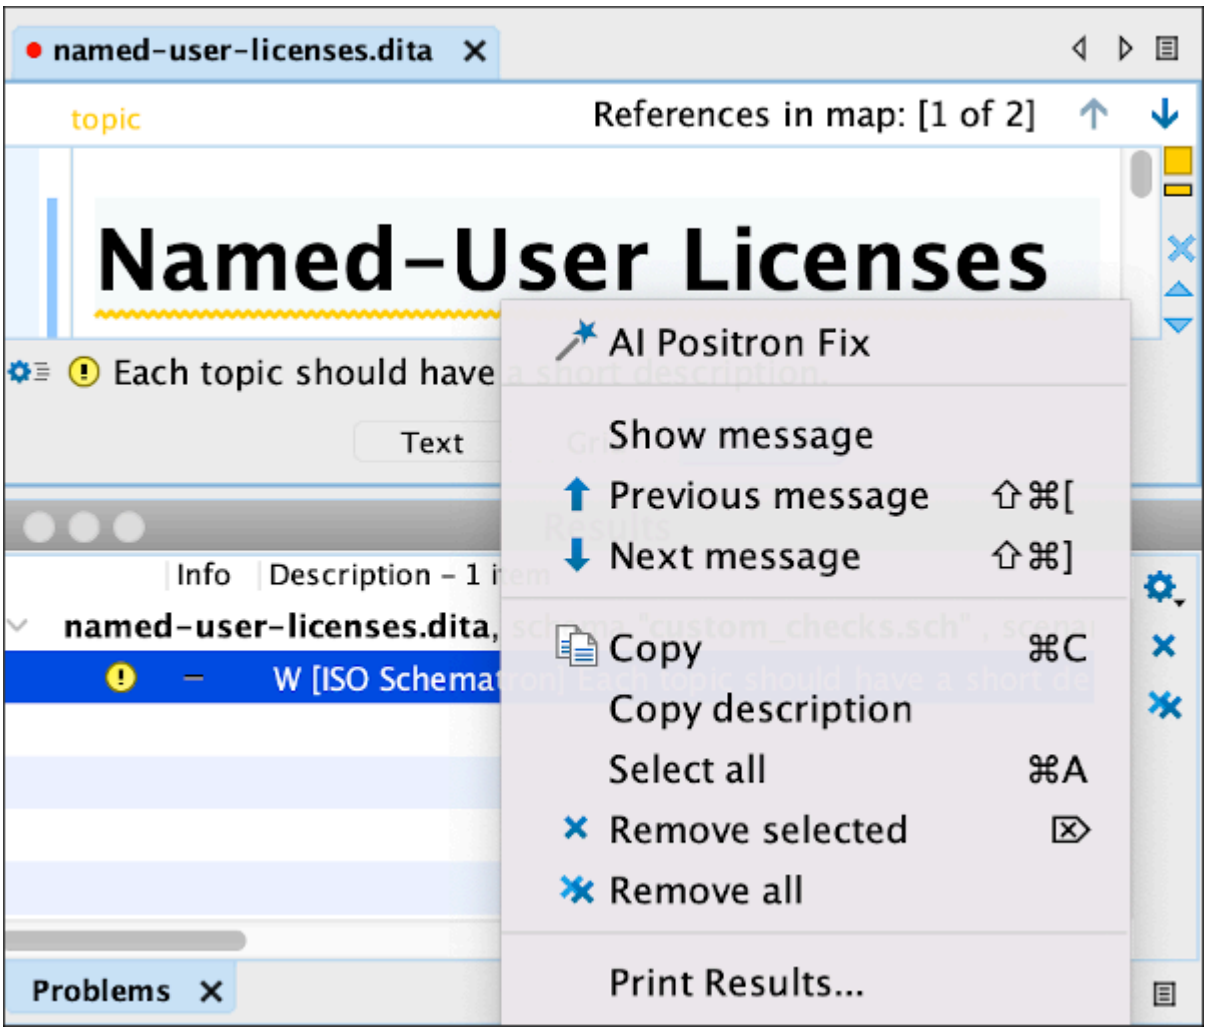
Currently, there is only one public platform that provides this service.

Default model

The default model is used for the chat pane and for actions that do not explicitly specify a fixed model. Each chosen model consumes a certain number of credits *(on page 2690)* per token.

Validation Quick Fixes

When validation problems are displayed in the **Results** pane, you can right-click on a problem and use the **AI Positron Fix** action to ask the **AI Positron** platform for help with fixing the problem. It will propose content in the chat pane (within the **AI Positron Assistant** view) that can be used to solve the problem.



Creating Custom Actions

In the AI Positron Assistant preferences page *(on page 2697)*, you can define a reference to a folder that contains custom actions.

Once the add-on is installed, the **New Document** wizard *(on page 377)* can be used to create either a new **AI Positron Custom Action** file that contains a custom action definition in JSON format or an **AI Positron Custom Actions List** that contains a JSON array with multiple defined actions. Validation and content completion are automatically provided for such custom action files. If the action definition files are saved in the custom actions folder defined in the **AI Positron Assistant** preferences page, the **AI Positron Assistant** view should automatically reload its **Actions** drop-down list to include them.

The most simple action defines an action id, title, type, and context:

```
{
    "id": "my.action.id",
    "title": "Improve Grammar",
    "type": "replace-selection-with-fragment",
    "input-type": "markup",
    "context": "Improve grammar in the following content preserving the XML markup:"
}
```

Defined actions can contain expandable parameters and their values can be customized before invoking the action:

```
{
   "id": "my.action.id",
   "title": "Improve Grammar",
   "type": "replace-selection-with-fragment",
   "input-type": "markup",
   "context": "${style} Improve grammar in the following content preserving the XML markup:",
   "expand-params":[
   {
           "name": "style",
           "label": "Style",
           "value": "",
           "alternate-values": ["Use active voice.", "Use passive voice."],
           "alternate-value-labels": ["Active voice", "Passive voice"],
           "choice-type": "single-choice"
    }
  ]
}
```

Create Custom Prompts/Actions by Recording Changes

The  **Record** button in the top-left corner of the view allows you to create new AI actions. It opens the **Record examples for instructions** dialog box where you can provide a set of instructions that are intended for the AI to follow. Then, after clicking the **Start recording** button at the bottom of the dialog box, you can record a collection of examples in the editing area that will help the AI better follow the given instructions. The examples are recorded from the changes made in the open editors.

After providing examples, you need to click the **Record** button again to stop the recording. You will then have the opportunity to save the final result as either a Positron action or as a favorite chat prompt.

For example, if you want to add DITA markup to menu cascades, you can follow these steps:

1. Click the **Record** button.
2. In the **Record examples for instructions** dialog box, enter some instructions like: *You are a technical writer. Add DITA markup to menu cascades.*
3. Click **Start recording**.
4. Open a DITA topic that has a menu cascade without markup (for example: `File > Export`).
5. Edit the topic and add markup, transforming it to:

```
<menucascade>
  <uicontrol>File</uicontrol>
  <uicontrol>Export</uicontrol>
</menucascade>
```

6. Click the **Record** button again to stop the recording. The system generates the following instructions with examples:

```
You are a technical writer. Add DITA markup to a menu cascades.
###
Input:
        <p>File > Export</p>

Output:
      <p><menucascade><uicontrol>File</uicontrol>
      <uicontrol>Export</uicontrol></menucascade></p>

Input: ${selection}
Output:
```

7. In the resulting dialog box, save the final result as either a Positron action or as a favorite chat prompt.

Custom Validation Rules

The add-on contributes two XPath extension functions (available in the content completion proposals for Schematron, XSLT, XQuery, and XPath) that can be used to rephrase content or to perform validation checks on existing content:

`ai:transform-content(instruction, (user, agent,)* content)`

Use this function from namespace *http://www.oxygenxml.com/ai/function* to automatically transform content using AI.

The function has the string parameters:

- `instruction` - The OpenAI instruction to be performed on the content.
- `user, agent` - You can add multiple pairs of user-agent data that will be passed to the AI as the history of the conversation.
- `content` - The content to be transformed.

It returns a string that represents the transformed content.

Here is an example of a custom Schematron schema that uses the `transform-content` function to correct the number of words used in a short description:

```
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt3"
    xmlns:sqf="http://www.schematron-quickfix.com/validator/process">
    <sch:ns uri="http://www.oxygenxml.com/ai/function" prefix="ai"/>
    <sch:pattern>
        <sch:rule context="shortdesc">
            <sch:report test="count(tokenize(.,'\s+')) > 50" sqf:fix="rephrase">
      The phrase must contain less than 50 words.</sch:report>
            <sqf:fix id="rephrase">
                <sqf:description>
                    <sqf:title>Rephrase phrase to be less that 50 words</sqf:title>
                </sqf:description>
                <sqf:replace match="text()" select="ai:transform-content(
                'Reformulate phrase to be less that 50 words', .)"></sqf:replace>
            </sqf:fix>
        </sch:rule>
    </sch:pattern>
</sch:schema>
```

`ai:verify-content(instruction, (user, agent,)* content)`

Use this function from namespace *http://www.oxygenxml.com/ai/function* to automatically validate content using AI.

The function has two string parameters:

- `instruction` - The OpenAI instruction to be performed on the content.
- `user, agent` - You can add multiple pairs of user-agent data that will be passed to the AI as the history of the conversation.
- `content` - The content to be validated.

It returns a boolean value that represents the result of the validation.

Here is an example of a custom Schematron schema that uses the `verify-content` function to check a short description for instances of a passive voice:

```
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt3"
  xmlns:sqf="http://www.schematron-quickfix.com/validator/process">
```

```
  <sch:ns uri="http://www.oxygenxml.com/ai/function" prefix="ai"/>
  <sch:pattern>
    <sch:rule context="shortdesc">
      <sch:report test="ai:verify-content('Does the following content has passive
 voice?', .)"
           sqf:fix="rephrase">The phrase uses passive voice.</sch:report>
      <sqf:fix id="rephrase">
         <sqf:description><sqf:title>Rephrase text to be active voice</sqf:title>
</sqf:description>
         <sqf:replace match="text()"
                select="ai:transform-content('Rephrase text to be active voice', .)"/>
         </sqf:fix>
      </sch:rule>
  </sch:pattern>
</sch:schema>
```

Blog Post About AI Positron Add-on By Tom Johnson

Oxygen AI Positron Assistant Enterprise

The **Oxygen AI Positron Assistant Enterprise** add-on provides advanced support for technical documentation writers throughout their content creation process by using a company-specific AI service (by configuring your company's specific **OpenAI** key, **Microsoft Azure OpenAI Service** connection, or **Anthropic Claude**).

A detailed list of actions and functionality available in the add-on is presented in the Oxygen AI Positron Assistant *(on page 2688)* topic.

Installation

To install this add-on, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

2. Select the **Oxygen AI Positron Assistant (Enterprise)** add-on and click **Next**.

   > **Important:**
   > There are two different iterations of the add-on and you can only have one or the other installed at once:
   > - **Oxygen AI Positron Assistant** - The regular version of the add-on.
   > - **Oxygen AI Positron Assistant (Enterprise)** - This Enterprise version is for those who want to connect to their own **OpenAI**, **MS Azure OpenAI**, or **Anthropic Claude** account.

3. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
4. Restart the application.

Result: The **AI Positron Assistant (Enterprise)** side view is now available.

Licensing and Configuration

You can configure the company-specific AI service details in the AI Service Configuration Preferences Page *(on page 2704)*.

The **AI Positron Enterprise** add-on works free of charge with any Oxygen XML Editor installation using an **Enterprise** license type for Oxygen XML Editor.

If your license of Oxygen XML Editor is not an **Enterprise** license, a special license key needs to be purchased for the add-on to enable this direct access. You can use the **Register** button in the **AI Positron Assistant** side view to configure the special license key.

> **Important:**
> If you want to use the default **Oxygen AI Positron** service instead of a company-specific AI service, the Oxygen AI Positron Assistant *(on page 2688)* add-on needs to be installed and used instead of the one listed above.

Note:
If you are an integrator using the Web Author Component in your own solution and you want to license the **AI Positron Enterprise for Web Author**, you can set a dedicated license server for AI Positron.

AI Service Configuration Preferences Page

Various service-related connection settings can be configured in **Options > Preferences > Plugins > Oxygen AI Positron Assistant (Enterprise) > AI Service Configuration**:

AI Connector

Specifies the connector type: **OpenAI**, **Microsoft Azure OpenAI** or **Anthropic Claude**.

OpenAI:

If **OpenAI** is chosen as the connector type, the following settings are available:

Address

The web address of the OpenAI service. By default: `https://api.openai.com`.

API key

The **OpenAI** API key necessary to work with the connector.

Note:
This option does not get saved in the Project-level options.

Organization ID

For users who belong to multiple organizations, they can specify which organization is used for an API request. Usage from these API requests will count as usage for the specified organization.

Default model

The default model is used for the chat view and for actions that do not explicitly specify a model.

Enable text moderation

This setting applies moderation (checks whether content complies with OpenAI's usage policies) to both the input text sent to the AI service and the response received from the AI service. It is enabled by default.

Tip:

By default, when executing an action using the **OpenAI** connector, three requests are made:

- A moderation on input content request to `configured_web_address/v1/moderations`.
- A completion request to `configured_web_address/v1/chat/completions`.
- A moderation on content returned by AI to `configured_web_address/v1/moderations`.

If your AI service does not require moderation (for example, moderation is already made by chat/completions endpoint) you can disable it by unchecking this checkbox.

Extra Headers

Extra name/value parameters to set in the headers that are specific for the AI requests.

Tip:
If the service uses **Bearer Authentication**, you can specify the key in the **Key** text field. If another authentication method is used, the **Key** field can be left empty, and the **Extra Headers** table can be used to set the authentication info on the request header. Note that editor variables can be used in this field and you can set your key in editor variables and specify the value in this table like this: `${env(AI_SERVICE_KEY)}` to access pre-set values of environmental variables.

MS Azure OpenAI:

If **Microsoft Azure OpenAI** is chosen as the connector type, the following settings are available:

Endpoint

The web address where the connector service is located. This value can be found in the **Keys & Endpoint** section when examining your resource from the **Azure** portal. For example: `https://your-company-name.openai.azure.com/`.

Deployment

The deployment name that was chosen when the model was deployed in **Microsoft Azure**.

API key

The **Microsoft Azure OpenAI Service** key necessary to work with the connector.

If you do not specify an API key, the add-on will try to use environment variables to authenticate using Microsoft Entra ID.

To use this method, you must create a service principal and assign a role to it that allows access to the Azure OpenAI service (e.g. the Cognitive Services OpenAI User role).

The connector supports these authentication methods:

Service principal authentication using a client secret

For this type of authentication, create a client secret and set these environment variables:

Variable name	Value
AZURE_CLIENT_ID	ID of a Microsoft Entra application.
AZURE_TENANT_ID	ID of the application's Microsoft Entra tenant.
AZURE_CLIENT_SECRET	One of the application's client secrets.

Service principal authentication using a client certificate

For this type of authentication, set up a certificate and set these environment variables:

Variable name	Value
AZURE_CLIENT_ID	ID of a Microsoft Entra application.
AZURE_TENANT_ID	ID of the application's Microsoft Entra tenant.
AZURE_CLIENT_CERTIFICATE_PATH	Path of a PFX/PEM certificate file
AZURE_CLIENT_CERTIFICATE_PASS-WORD	Password for a PFX/PEM certificate

Username and password authentication

For username and password authentication, set these environment variables:

Variable name	Value
AZURE_CLIENT_ID	ID of a Microsoft Entra application.
AZURE_TENANT_ID	ID of the application's Microsoft Entra tenant.
AZURE_USERNAME	A username (usually an email address).
AZURE_PASSWORD	The associated password for the given username.

Note:
Oxygen XML Editor should be restarted after each environment variable change for the changes to take effect.

Vision-specific Settings

Vision-specific settings are only used when images are attached in the Chat panel or sent to the AI engine with specific actions (e.g. **Generate Documentation Draft**).

Vision - Endpoint

Optional Azure AI deployment endpoint that can analyze images using **Vision**. This setting specifies the web address where the connector service is located. This value can be found in the **Keys & Endpoint** section when examining your resource from the **Azure** portal. For example: `https://your-company-name.openai.azure.com/`.

Vision - Deployment

Optional deployment name that was chosen when the **Vision** model was deployed in **Microsoft Azure**.

Vision - API key

Optional **Microsoft Azure OpenAI Service** for the endpoint that can analyze images using **Vision**.

Extra Headers

Extra name/value parameters to set in the headers that are specific for the AI requests.

Anthropic Claude:

If **Anthropic Claude** is chosen as the connector type, the following settings are available:

Endpoint

The web address where the connector service is located. By default, it is `https://api.anthropic.com/`.

API key

The **Anthropic Claude** API key necessary to work with the connector.

Model

The Anthropic Claude model to use. By default, it is `claude-3-opus-20240229`.

Extra Headers

Extra name/value parameters to set in the headers that are specific for the AI requests.

Note:
You can use editor variables *(on page 332)* such as `${env(ENV_NAME)}` in all configuration and header parameter values.

Troubleshooting:
If the add-on fails to connect with the custom settings, it might be useful to enable debug logging in the application to see what requests and responses are made to/from the AI server. You can enable debug logging *(on page 3041)* in the application by adding a `logback.xml` file in the application's installation folder. A minimal `logback.xml` configuration XML file content to enable logging only for the AI Positron add-on's connections would look like this:

```
<configuration>
  <appender name="R2" class="ch.qos.logback.core.rolling.RollingFileAppender">
    <file>${user.home}/Desktop/oxygenLog/oxygen.log</file>
    <rollingPolicy class="ch.qos.logback.core.rolling.FixedWindowRollingPolicy">
      <fileNamePattern>${user.home}/Desktop/oxygenLog/oxygen%i.log.gz</fileNamePattern>
      <minIndex>1</minIndex>
      <maxIndex>20</maxIndex>
    </rollingPolicy>
    <triggeringPolicy class="ch.qos.logback.core.rolling.SizeBasedTriggeringPolicy">
      <maxFileSize>12MB</maxFileSize>
    </triggeringPolicy>
    <encoder>
      <pattern>%r %marker %p [ %t ] %c - %m%n</pattern>
    </encoder>
  </appender>
  <logger name="com.oxygenxml.positron.connector.openai" level="debug"/>
  <logger name="com.oxygenxml.positron.core" level="debug"/>
  <root level="error">
    <appender-ref ref="R2"/>
  </root>
</configuration>
```

Important:
The logging information will be copied in the `Desktop/oxygenLog` folder once the application is started. To avoid performance problems, the `logback.xml` file must be deleted once the logging has been obtained.

Oxygen AI Positron Assistant *(on page 2688)*

Oxygen Emmet Plugin

An **Oxygen Emmet Plugin** is available as an add-on and it provides the means for high-speed coding and editing in **Text** mode or **Author** mode via a content assistance mechanism. It can be used for HTML, XSL, CSS, LESS, and other formats. For example, with the Emmet add-on installed, you can type abbreviations (similar to CSS selectors) and expand them into full-fledged HTML code. The add-on contributes a submenu named **Emmet** in the contextual menu and it contains actions for expanding abbreviations or wrapping content with an expanded abbreviation. The two actions can also be invoked using the **Alt + Shift + E (Ctrl + Shift + E on macOS)** or **Alt + Shift + W (Ctrl + Shift + W on macOS)** keyboard shortcuts.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install this add-on, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

   Tip:
   For HTML, CSS, LESS, or XSL files, you can simply right-click anywhere in the editor pane and select **Emmet** from the pop-up menu.

2. Select the **Oxygen Emmet Plugin** add-on and click **Next**.
3. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
4. Restart the application.

Result: The Emmet actions will now be available using the keyboard shortcuts or in the **Emmet** submenu (located in the contextual menu of **Text** mode or **Author** mode.

Emmet Actions

The two contributed actions are:

Expand abbreviation [Alt + Shift + E (Ctrl + Shift + E on macOS)]

In **Text** mode, after entering an abbreviation, invoking this action will expand a valid abbreviation into a code snippet, depending on the document type.

In **Author mode**, invoking the action opens a dialog box where you can enter an abbreviation. After you click **OK**, a valid abbreviation is expanded into a code snippet, depending on the document type.

> **Tip:**
> For HTML, CSS, LESS, or XML-based document types, you can also use **Ctrl + Space** to expand Emmet abbreviations.

Wrap with abbreviation [Alt + Shift + W (Ctrl + Shift + W on macOS)]

It opens a dialog box where you can enter an abbreviation and after clicking **OK**, the abbreviation is expanded with the selected content added in the last element of the generated snippet.

Abbreviation Expansion Examples

Here are some examples for HTML:

- **Expand abbreviation** example:

```
#page>div.logo+ul#navigation>li*5>a{Item $}
```

expands into:

```
<div id="page">
  <div class="logo"></div>
  <ul id="navigation">
    <li><a href="">Item 1</a></li>
    <li><a href="">Item 2</a></li>
    <li><a href="">Item 3</a></li>
    <li><a href="">Item 4</a></li>
    <li><a href="">Item 5</a></li>
  </ul>
</div>
```

- **Wrap with abbreviation** example:

If the following content is selected to be wrapped:

```
About
News
Products
Contacts
```

then

```
ul>li[title=$#]*>{$#}+img[src=https://www.ex1.com/$#][alt=item$]
```

expands into:

```
<ul>
    <li title="About">About<img src="https://www.ex1.com/About" alt="item1"></li>
    <li title="News">News<img src="https://www.ex1.com/News" alt="item2"></li>
    <li title="Products">Products<img src="https://www.ex1.com/Products" alt="item3"></li>
    <li title="Contacts">Contacts<img src="https://www.ex1.com/Contacts" alt="item4"></li>
</ul>
```

You can also use Emmet abbreviations for other XML documents. Here are some examples of expanded abbreviations for DITA:

- `prolog>author {AuthorName}`

  expands into:

  ```
  <prolog>
    <author>AuthorName</author>
  </prolog>
  ```

- `simpletable>(strow>stentry*4)*4`

  expands into a 4x4 simple table.

- `ul>li*3`

  expands into an unordered list with 3 list items.

- `ol>li[id="item$"]*3`

  expands into:

  ```
  <ol id="ol_gff_bjd_mkb">
    <li id="item1"/>
    <li id="item2"/>
    <li id="item3"/>
  </ol>
  ```

Here are a few CSS examples:

- `@f+`

  expands into:

```
@font-face {
  font-family: 'FontName';
  src: url('FileName.eot');
  src: url('FileName.eot?#iefix') format('embedded-opentype'),
       url('FileName.woff') format('woff'),
       url('FileName.ttf') format('truetype'),
       url('FileName.svg#FontName') format('svg');
  font-style: normal;
  font-weight: normal;
}
```

- `-br`

  expands into:

```
  -webkit-border-right: ;
  -moz-border-right: ;
  -ms-border-right: ;
  -o-border-right: ;
  border-right: ;
```

> **Tip:**
> To see more examples of Emmet syntax, go to https://docs.emmet.io/cheat-sheet/.

Emmet Documentation

Live Tutorials Add-on

An add-on is available that contributes a view that provides the ability to create, run, and check progress for tutorials directly in Oxygen XML Editor. Once the add-on is installed, a **Tutorials** view is available that shows the available tutorials and allows missions to be followed.

The add-on comes bundled with a set of tutorials for learning to work with the **DITA XML** standard and you also have the ability to create your own tutorials *(on page 2716)*. Each tutorial contains one or more missions. A *mission* consists of initial file content that is opened in the application and a set of steps and hints for guidance. The mission is considered complete when the initial content is changed by the end user to match an expected result.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow this procedure:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.

   Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

2. Select the **Live Tutorials** add-on and click **Next**.
3. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
4. Restart the application.

Result: The **Tutorials** view is now available. To open the view, select **Tutorials** from the **Window > Show View** menu.

Loading Tutorials

The add-on comes bundled with a set of tutorials for learning to work with the **DITA XML** standard. For example, there are tutorials that contain various missions for learning some basic DITA editing tasks, learning how to work with tables, learning how to edit and insert images, reuse content, and more. Additional tutorials can be loaded from a specified location in the **Options > Preferences > Plugins > Live Tutorials** page.

Extra tutorials files (with the fixed name `tutorial.xml`) that are located within various folders in the **Project** view will also be loaded automatically.

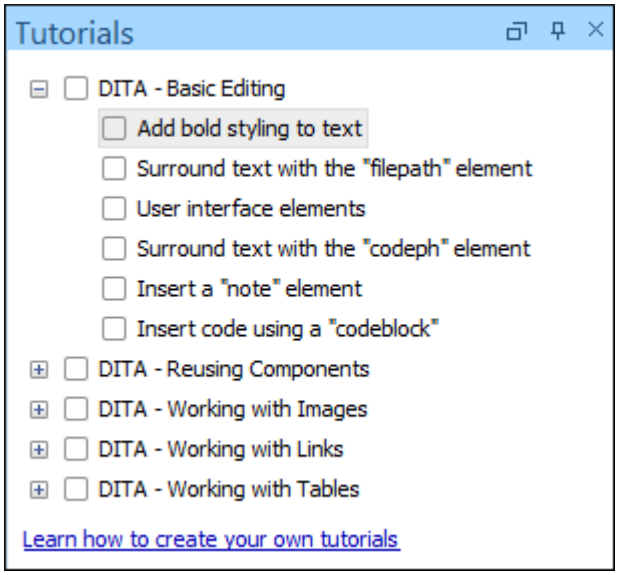
You can also create your own tutorials *(on page 2716)* and use them with the add-on.

Tutorials View

Once the **Live Tutorials** add-on is installed, the **Tutorials** view is available by selecting it from the **Window > Show View** menu.

The **Roadmap** is the main interface of the add-on, where all the available tutorials are presented along with the actions that can be triggered regarding the tutorials.

Figure 628. Tutorials View - Roadmap



The **Roadmap** panel includes the following actions/features:

Tutorials list

This is a list of all the available tutorials. Each tutorial is an entry, with its own progress icon displayed on the left side. The following actions are available in the **Tutorials** list:

Start mission

Double-click, press ENTER, or right-click and choose **Start mission** on any selected mission to begin a new mission. Missions can be started in any order.

Reset mission progress

Right-click on a mission and choose **Reset progress** to reset its current progress.

Learn how to create your own tutorials help link

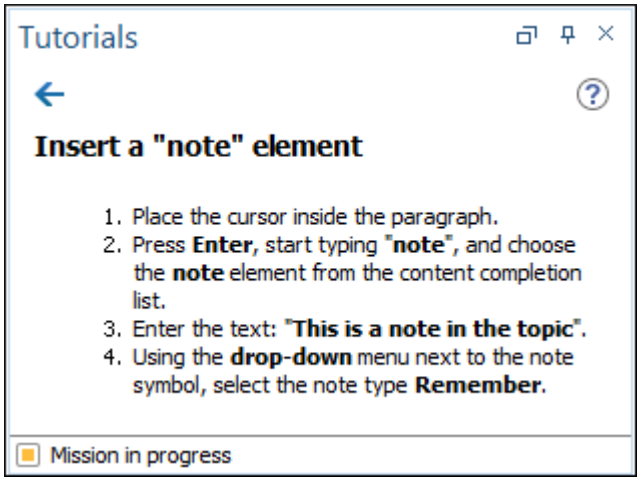
Opens the user guide help pages of the add-on in the preferred browser.

Learn how to create your own tutorials link

Opens the user guide of the add-on in the preferred browser.

Once a mission is opened from the **Roadmap**, the **Tutorials** view changes to display the selected mission.

Figure 629. Tutorials View - Mission Progress



The **Mission Progress** panel shows the overall status of the current mission. The following actions/features are available:

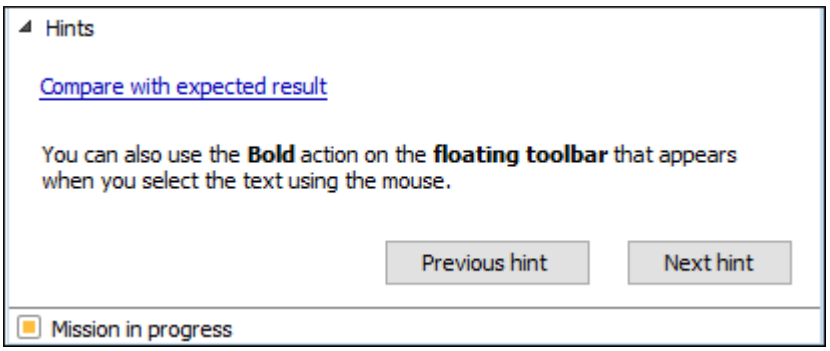
Back

Navigates back to the **Roadmap** missions list.

Hints

Opens the collapsible/expandable **Hints** pane that gives you access to various hints to help you complete the current mission.

Figure 630. Hints Pane



The **Hints** pane has the following features:

Compare with expected result *link*

Opens a visual file comparison tool with the current mission's edited file on the left side and the expected file content from the finished tutorial on the right side.

Hint details *section*

Presents details about the current hint.

Previous/Next hint *buttons*

Navigates between available hints.

Mission details

Details are displayed in the mission panel about what the mission consists of and the steps needed to complete it.

Completing a Mission

Once a mission is started, details about how to complete the mission and hints are available. The initial mission file is opened and the add-on will automatically check it to check when it matches the expected content. Upon completing a mission, the **Mission Accomplished** dialog box is shown and the **Next Mission** button becomes available to progress to the next mission.

Creating New Tutorials

Once the add-on is installed, you can create new tutorials that can later be loaded from the **Options > Preferences > Plugins > Live Tutorials** page. Each **tutorial** loaded by the add-on must have an associated configuration file named `tutorial.xml`, where details about the tutorial and the corresponding missions, as well as activity files and hints, are defined.

First, you should create a folder that will contain both the `tutorial.xml` file and other resources necessary for the tutorial.

Then use the New Document Wizard *(on page 377)* and search for the **tutorial template**. Select **Live Tutorials/ tutorial** and save it as `tutorial.xml` in the custom tutorial folder. A small sample tutorial folder can be downloaded from here.

The `tutorial.xml` file can be edited in the **Author** visual mode, which contains inline actions to add new missions, hints, or to browse for referenced resources.

Elements of a tutorial:

`<tutorial>`

The root element of the tutorial XML configuration file.

`<title>`

The title of a tutorial.

`<goal>`

An overall goal description for the tutorial (can contain escaped HTML content). It is displayed when hovering over the tutorial in the **Roadmap**.

`<mission>`

A tutorial has one or more missions. A mission is one of the many objectives that may appear in a tutorial. There has to be at least one mission in a every tutorial. A mission requires the following elements and attributes:

`@id`

An attribute of the mission element that is unique to a mission.

`<title>`

The title of the mission.

`<activity>`

The activity of the mission describes the steps to follow and contains the initial and expected files.

`<description>`

Describes the steps required to complete the activity. May contain escaped HTML content.

`<files>`

An activity requires two of file paths that are used to test if the user completed the steps of the activity.

`@projectFolder`

An optional reference to a folder where the resources for the mission are located. It can contain an **Oxygen Project File** (`.xpr`) that will automatically be opened when the mission starts. The folder needs to be created and referenced relative to the `tutorial.xml` file.

`@editPath`

Represents the path of a file that will serve as a starting point for the user to complete the mission. The edited file needs to be created and referenced relative to the `tutorial.xml` file.

`@expectedPath`

A reference to a file with expected content that is compared with the changes the end user performs in the edit file. The expected file needs to be created and referenced relative to the `tutorial.xml` file.

`@ignoreXPath`

An XPath expression that can be set to ignore certain elements or attributes when comparing the original and the user-modified file. For example, you can set it to `@id` to ignore all automatically generated IDs.

`<hint>`

A hint helps the user with more information when trying to complete an activity. The hint may contain embedded escaped HTML content. An activity can have zero or more hints.

Customizing the Default Tutorials

To customize the default tutorials, follow this procedure:

1. Copy the default tutorials from the installation directory of the add-on to a project and edit them as desired. Oxygen XML Editor automatically loads the tutorials found inside the current project.

   > **Tip:**
   > To find the location where the add-on is installed, go to **Options > Preferences > Plugins**, select **Live Tutorials** from the list of add-ons and look at the value of the **Location** property. In that location, there is a `tutorials` folder that contains all the default tutorials.

2. Once you have copied the tutorials to your project, you need to disable the loading of the default tutorials by going to **Options > Preferences > Plugins > Live Tutorials** and de-selecting the **Load default tutorials** option. You should also save the options from the **Live Tutorials** preferences page at the project level *(on page 321)* so that whenever someone opens your project, the custom tutorials will be loaded from it instead of the default tutorials.
3. If applicable, you can share your custom tutorials with others.

Resources

To see a visual demonstration of the Live Tutorials add-on, watch our webinar: Interactive Tutorials in Oxygen.

Writer Helper Add-on (Experimental)

Oxygen XML Editor offers an add-on that provides support for helping technical writers. Once the add-on is installed, a **Writer Helper** view is available from the **Window > Show View** menu. Once opened, you can use one of its available tabs to access the functionality.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field.

Note:
If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **Writer Helper** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart Oxygen XML Editor.

Result: The **Writer Helper** view now be available and can be selected from the **Window > Show View** menu.

Review

You can select folders or files in the **Project** view and start a review session for them. By default, the review is done in random order and all reviewed documents are opened with *change tracking* enabled. During the review process, you can see a list of already reviewed documents and check the status of your progress.

This feature is useful for reviewing a set of documents.

Similar Content

You can select folders or files in the **Project** view, then choose a list of elements to check for similarity. Once you start the **Find similar content** processing, information from all XML, HTML, and Markdown files is gathered to determine elements that have similar text content. Once the similar matches are presented, you can click on each of them to show a detailed list of places where the matches are found.

If the **Show similar content for the current file** checkbox is enabled and the similar elements have been found, once you open a document, a results tab will show elements the current document has in common with all other documents that were analyzed.

This feature is useful for finding possible elements that can be reused instead of being copy-pasted between documents.

Read Aloud

Select content in the current document and use the **Play** button to listen to how it is read by an operating system-specific narrator.

This feature is useful to review content by listening to it.

Tips

You can view a list of editing tips, tuned for technical writers. Each tip might also have a **Mode details** link to open the Oxygen XML Editor user guide.

This feature is useful for discovering productivity tips to help make your editing experience more efficient and productive.

Resources

For more information about the Writer Helper add-on, as well as details regarding other popular add-ons that extend the functionality of Oxygen XML Editor, watch the following webinar:

- Webinar: Add-ons You Can Use for Technical Writing

Development

XSpec Helper View Add-on

Oxygen XML Editor offers an add-on that contributes an **XSpec Test Results** view, that provides the ability to run XSpec test scenarios and view the results directly in the application.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open the add-on selection dialog box.
2. Paste **https://www.oxygenxml.com/InstData/Addons/community/updateSite.xml** in the **Show add-ons from** field (or select it from the drop-down menu).
3. Select the **XSpec Helper View** and **XSpec Framework** add-ons (both are required), and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

The add-on contributes a  **Run XSpec test scenarios** button on the main toolbar. Click that button to execute an XSpec file and open its results in the **XSpec Test Results** view. At this point you can do the following:

- Switch to the XSLT and use the **Run** buttons in this view to execute a particular scenario.
- For each test, there is also a **Show** button that selects the corresponding test in the main editing area.
- For failed tests, you can click a particular test to open a diff comparison between the expected and actual results.

For more information, see the details for this **Oxygen XSpec Helper View** add-on in GitHub.

Saxon XSLT and XQuery Transformer Add-on

Oxygen XML Editor offers an add-on that installs an external Saxon XSLT and XQuery processor and allows you to validate and transform XSLT and XQuery documents with that external processor. The default add-on update site includes versions for Saxon 9.6, 9.7, 9.8, 9.9, 10.7, 10.9, 11.6, and 12.4.

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select one of the versions of the **Saxon XSLT and XQuery Transformer** add-on (**9.6**, **9.7**, **9.8**, **9.9**, **10.7**, **10.9**, **11.6**, or **12.4**) and click **Next**.

   Note:
   If you have issues connecting to the default update site, you can download the package for either Saxon 9.6, Saxon 9.7, Saxon 9.8, Saxon 9.9, Saxon 10.9, Saxon 11.6, or Saxon 12.4, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file and install them one by one.

4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

   Result: When you configure the validation or transformation scenario, you will now have the option to choose the particular Saxon transformer.

   Restriction:
   Debugging XSLT/XQuery transformations based on this engine is **NOT** supported.

XSD to JSON Schema Converter

Oxygen XML Editor includes a tool for converting an XML Schema file (XSD) to a JSON Schema file. The **XSD to JSON Schema** action for invoking the tool can be found in the **Tools > JSON Tools** menu. It requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor will present a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **XSD to JSON Schema** action will invoke the tool.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **XSD to JSON Schema** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **XSD to JSON Schema** dialog box is now available and can be selected from the **Tools > JSON Tools** menu.

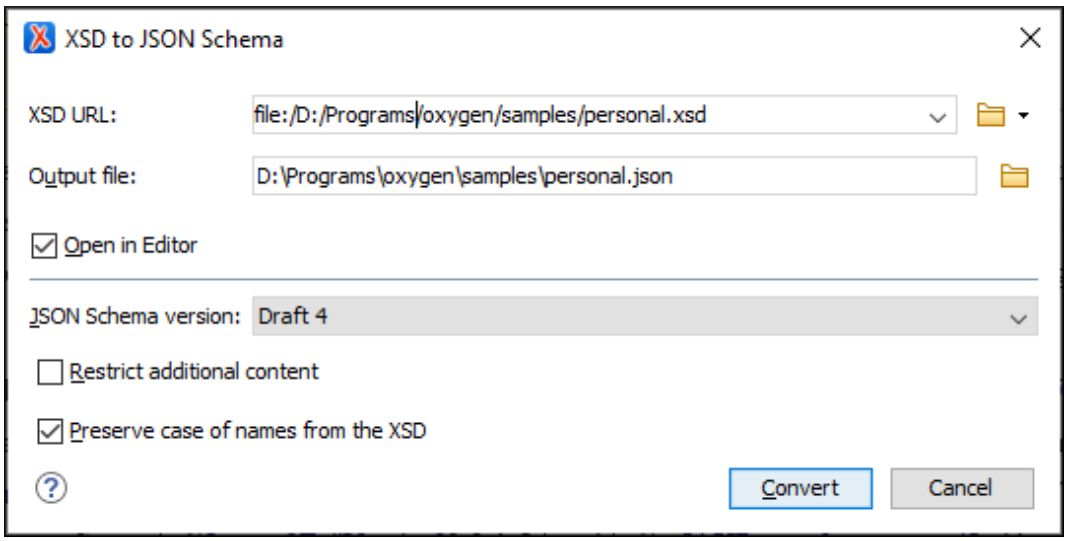
Converting XSD to JSON Schema

To convert an XML Schema (XSD) to a JSON Schema, follow these steps:

1. Select the **XSD to JSON Schema** action from the **Tools > JSON Tools** menu.

   Step Result: The **XSD to JSON Schema** dialog box is displayed:

Figure 631. XSD to JSON Schema Dialog Box



2. In the **XSD URL** field, choose or enter the URL of the XML Schema document. The conversion supports XSD versions 1.0 and 1.1.
3. In the **Output file** field, choose the path for the resulting output file.
4. [Optional] You can select the **Open in Editor** option to open the resulting JSON Schema document in the main editing pane.
5. For the **JSON Schema version** option, choose the version of the resulting JSON schema. The possible choices are: **Draft 4**, **Draft 6**, **Draft 7**, **2019-09**, and **2020-12**.
6. [Optional] If you select the **Restrict additional content** option, then `additionalProperties` (for objects) and `additionalItems` (for arrays) will be set to `false` in the resulting schema. By default, these keys are not in the schema, meaning that providing additional content (according to the schema) is allowed.
7. [Optional] You can select the **Preserve case of names from the XSD** option if you want the names from the XSD to remain unchanged in the resulting JSON Schema. Otherwise, the default JAXB naming algorithm will be applied (for example, "`some.nAMe`" is changed to "`SomeNAMe`", or "`Some_oth3r_name`" is changed to "`SomeOth3RName`").
8. Click the **Convert** button.

Result: The original XSD document is now converted to a JSON Schema document. The resulting JSON Schema will be the specified draft and will contain:

- The `$id` of the schema, generated from XSD `targetNamespace`.
- The `$definitions` section, which declares `complex` and `enum` types.
- The `anyOf` section, which lists possible top-level elements as an array of objects.

Other Possible Results:

- If an XSD type extends another type, then its schema is combined with the schema of the base type using the `allOf` keyword.
- If an extension in XSD defines an element with the same name as an attribute in the base, a property named `rest` is generated to avoid name conflicts in JSON.
- If a property of a complex type is a collection property, the schema of the collection items will be wrapped in the JSON array schema.

Conversion Mappings

The following table lists the specific conversion mapping details.

XML Schema Type	JSON Schema Representation
anySimpleType	string, number, integer, boolean, null
anyType	string, number, integer, boolean, null, object, array
string	string
normalizedString	string
token	string
language	string
Name	string
NCName	string
ID	string
IDREF	string
IDREFS	array of strings
ENTITY	string
ENTITIES	array of strings
NMTOKEN	string
NMTOKENS	array of strings
boolean	boolean
base64Binary	array of integers
hexBinary	array of integers
float	number
decimal	number
integer	integer
nonPositiveInteger	integer

XML Schema Type	JSON Schema Representation
negativeInteger	integer
long	integer
int	integer
short	integer
byte	integer
nonNegativeInteger	integer
unsignedLong	integer
unsignedInt	integer
unsignedShort	integer
unsignedByte	integer
positiveInteger	integer
double	number
anyURI	string with "format":"uri"
QName	object with "namespaceURI", "localPart", "prefix"
duration	string
dateTime	string with "format":"date-time"
date	string with "format":"date"
time	string with "format":"time"

Conversion Limitations

In most cases, the conversion creates an equivalent schema, but there are some limitations:

- Restrictions/facets are not taken into consideration when converting (`fractionDigits, pattern, totalDigits, whiteSpace`, `minInclusive`, `maxInclusive`, and the restrictions for length, except `enumeration`). However, extensions and indicators are properly converted (`minOccurs, maxOccurs, group, sequence, choice`).
- The `<documentation>` element is not converted into `<description>`.
- The `@substitutionGroup` attribute for an element that has no declared type becomes a reference to the element that can substitute it.
- The `@block` attribute is not taken into consideration during the conversion.

Generating Java Classes from XML Schema

Oxygen XML Editor includes a tool for generating Java classes from an XML Schema (XSD) file. The **Generate Java classes from XML Schema (XSD)** action for invoking the tool can be found in the **Tools** menu. It requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor will present a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the action will invoke the Java class generator tool.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **Java Classes Generator** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **Generate Java classes from XML Schema (XSD)** dialog box is now available and can be selected from the **Tools** menu.

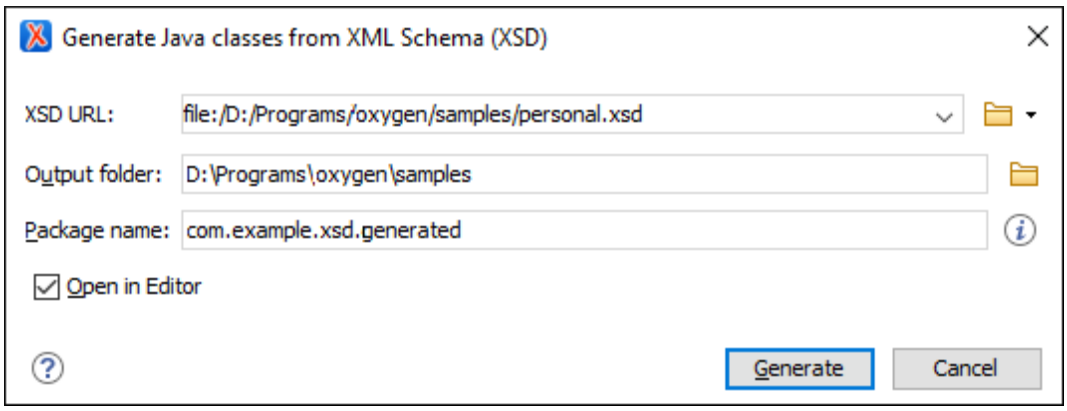
Generating Java Classes

To generate Java classes, follow these steps:

1. Select the **Generate Java classes from XML Schema (XSD)** action from the **Tools** menu.

   Step Result: The **Generate Java classes from XML Schema (XSD)** dialog box is displayed:

Figure 632. Generate Java Classes from XML Schema (XSD) Dialog Box



2. Choose or enter the **XSD URL** of the XML Schema document.
3. Choose the path for the **Output folder** where the generated files will be stored.
4. [Optional] You can choose the **Package name** for the Java package that will contain the generated source files. If not specified, the name will be generated based on the value of the `@targetNamespace` attribute.
5. [Optional] You can select the **Open in Editor** option to open the `ObjectFactory.java` file in the editor. This java class contains factory methods for all other classes in the package.
6. Click the **Generate** button.

Result: The Java class files will be generated inside the new package, located in the specified output folder.

Generating JSON Schema Documentation

Oxygen XML Editor includes a tool for generating documentation for a JSON Schema file in HTML format. To generate JSON Schema documentation, select **JSON Schema Documentation** from the **Tools > Generate Documentation** menu. You can also open the tool by using the **Generate Documentation** toolbar button. This opens a dialog box where you can specify the location of the JSON Schema file and HTML output file.

This tool requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor presents a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **JSON Schema Documentation** action will invoke the tool.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

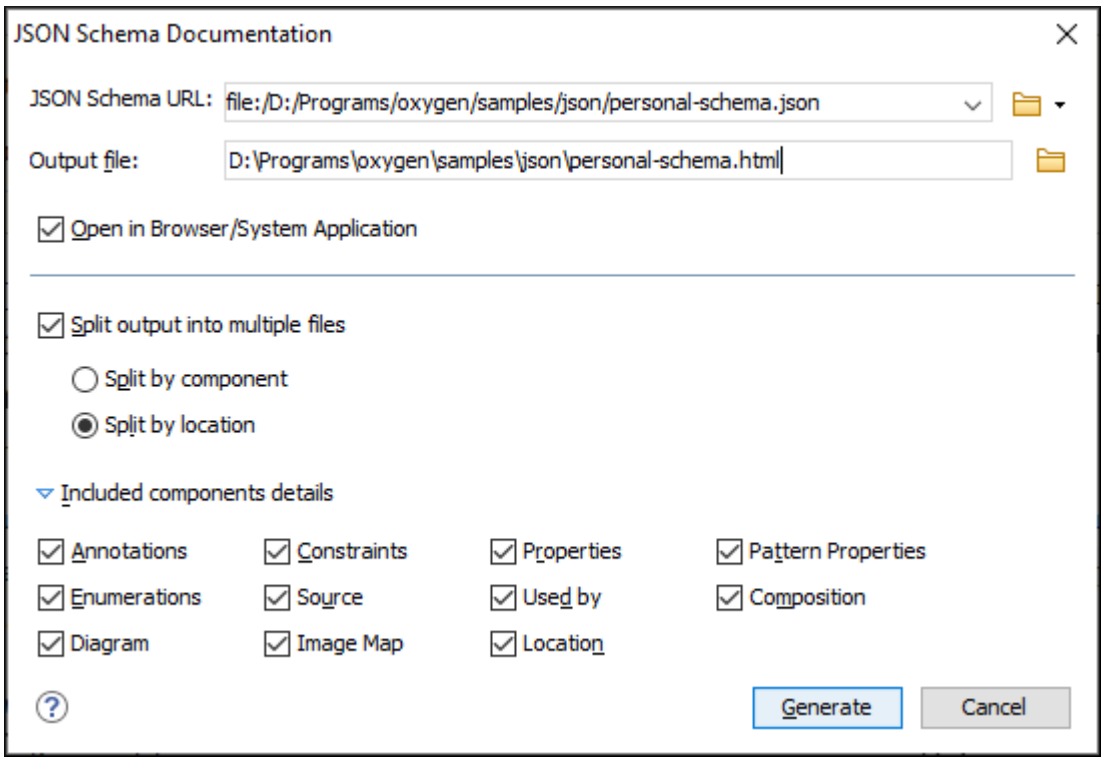
   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **JSON Schema Documentation** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **JSON Schema Documentation** dialog box is now available and can be selected from the **Tools > Generate Documentation** menu.

JSON Schema Documentation Dialog Box

Figure 633. JSON Schema Documentation Dialog Box



The **JSON Schema Documentation** dialog box includes the following fields and options:

JSON Schema URL

The URL of the JSON Schema file. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the **Browse** drop-down list. The tool supports

schemas with versions *Draft 04*, *06*, *07* and, starting with version 4.0.0 of the add-on, *2019-09* and *2020-12*.

Output file

The path to the folder where the generated HTML file will be saved.

Split output into multiple files

If selected, the application splits the output into multiple files. You can choose between splitting them by **component** name or **location**.

Open in Browser/System Application

If selected, the generated result is opened in the system application associated with the output file type (HTML).

Included component details

This section can be used to specify whether or not the following components are shown in the generated documentation:

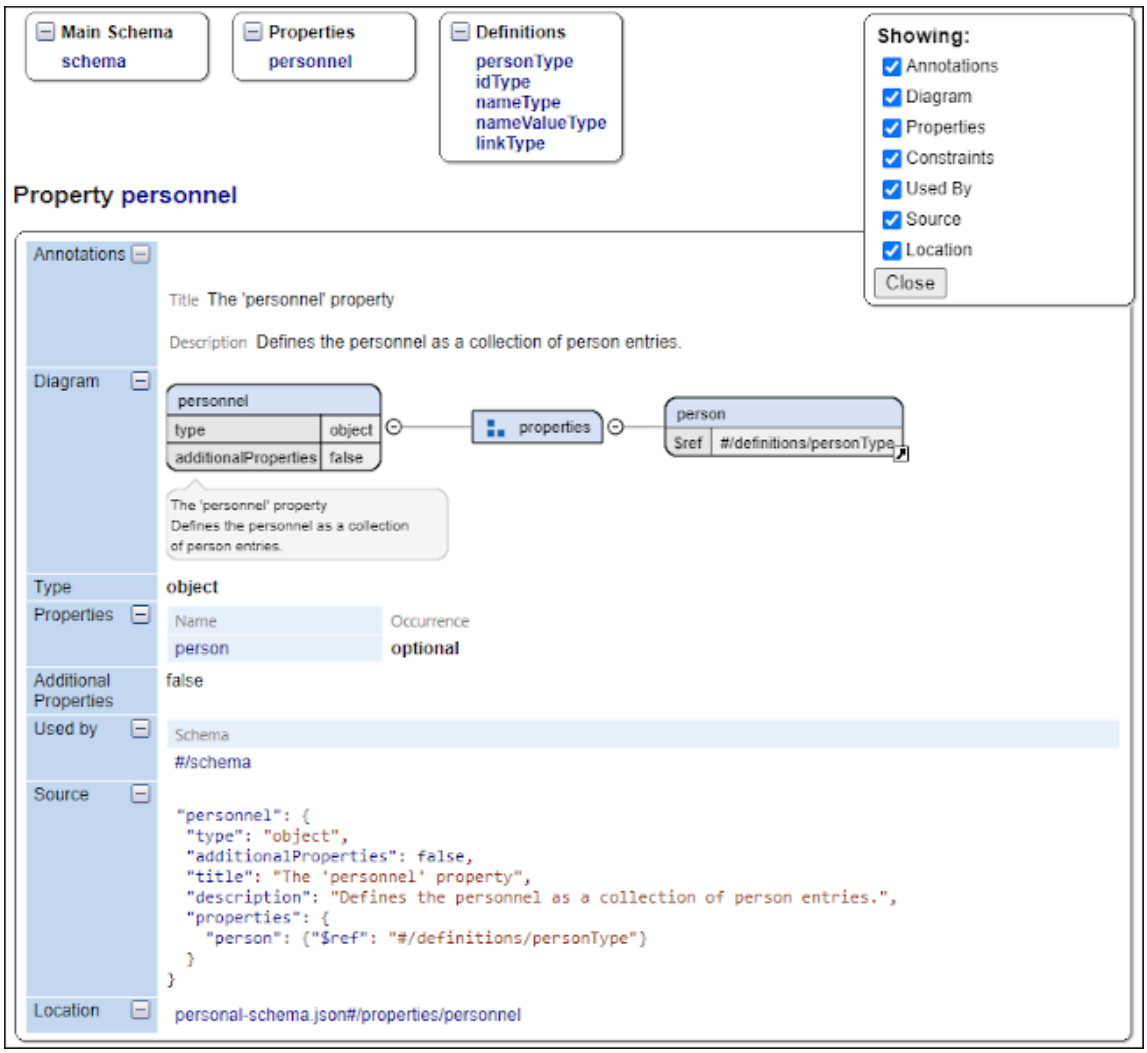
- **Annotations** - Displays the annotations (title, description) for each component (property or definition).
- **Constraints** - Displays the schema constraints for each component, according to its type.
- **Properties** - Displays the `properties` of an Object Schema.
- **Pattern Properties** - Displays the `patternProperties` of an Object Schema.
- **Enumerations** - Displays the enumerated values, if specified in the schema.
- **Source** - Displays the text schema source for each component.
- **Used By** - Displays the list of all the components that reference the current definition.
- **Composition** - Displays the `oneOf`, `anyOf`, and `allOf` compositors that are used for combining schemas.
- **Diagram** - Displays the diagram image for each component. The diagrams are generated according to the options specified in the **Schema Design** preferences page *(on page 206)*. Diagrams are also generated for components within schemas from referenced files.
- **Image Map** - Diagrams will include hyperlinks that navigate to each particular component.
- **Location** - Displays the schema location for each component.

You can click **Generate** at any point to generate the JSON Schema documentation.

Generated JSON Schema Documentation in HTML Format

After generating the JSON Schema documentation, it is presented in a visual diagram style with various sections, hyperlinks, and options.

Figure 634. JSON Schema Documentation Example Opened in a Browser



The generated documentation includes a Table of Contents on the left pane with links to particular sections in the right pane. You can collapse or expand details by using the **Showing** options or the **Collapse** or **Expand** buttons.

OpenAPI Tester

Oxygen XML Editor includes a testing tool for *OpenAPI* files. The tool provides the ability to inspect OpenAPI request responses and to ensure that they work as expected. It can be used for OpenAPI 3.x in JSON or YAML format.

To use the tool, select **OpenAPI Tester** from the **Tools > JSON Tools** menu. This opens a dialog box where you can specify the location of the OpenAPI file that you want to test.

This tool requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor presents a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **OpenAPI Tester** action will invoke the tool.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

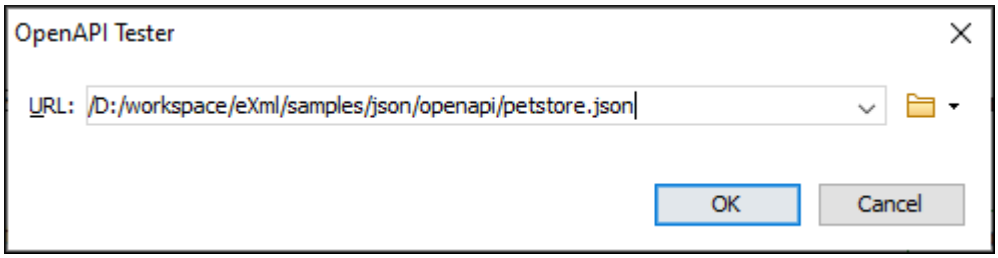
   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **OpenAPI Tester** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **OpenAPI Tester** dialog box is now available and can be selected from the **Tools > JSON Tools** menu.

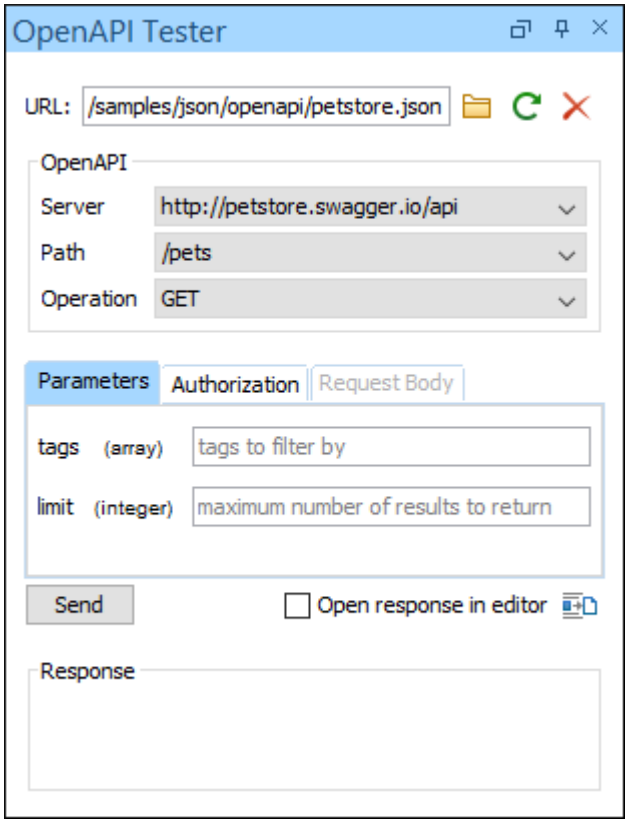
OpenAPI Tester Dialog Box

Figure 635. OpenAPI Tester Dialog Box



After selecting **OpenAPI Tester** from the **Tools > JSON Tools** menu, the **OpenAPI Tester** dialog box is displayed where you can select the URL for the OpenAPI document (either local or remote). After clicking **OK**, the **OpenAPI Tester** view becomes visible on the right side of the editor. The view can also be opened by selecting **OpenAPI Tester** from the **Window > Show View** menu.

Figure 636. OpenAPI Tester View



The tester loads the selected OpenAPI document and fills in the corresponding fields. The tester fields are as follows:

URL

The URL of the OpenAPI file. You can specify the path by using the text field or the **Browse** button. If you specify the path directly in the text field, you need to click the **Reload** button. You can use the **Clear** button if you want to remove all the content from the view.

Server

The list of servers defined by the OpenAPI document. The global "servers" array can be overridden on the path level or operation level. If it is not provided or is empty, the server URL defaults to "/".

Path

The list of individual endpoints (paths) in the API. The full request URL is constructed as `<server-url>/path`.

Operation

The list of HTTP operations supported by the selected path. OpenAPI 3.0 supports get, post, put, patch, delete, head, options, and trace.

Parameters tab

The definition of the parameters for the selected operation. OpenAPI 3.0 supports parameters passed via path, query string, headers, and cookies. The required parameters will be marked with a red asterisk. For array parameters, items must be separated by a comma.

Authorization tab

The list of available authentication types. The authentication data is persistent and can be removed from the contextual menu.

Request Body tab

The media type and the body of the request (if the selected operation allows it). For example, GET will not allow specifying a body since that HTTP method disallows it. Oxygen XML Editor will create a sample request body based on the JSON Schemas defined in the OpenAPI document. Usually, you just need to change a few values for the request to be valid.

Variables tab

The list of variables used for server templating (if applicable). Variables are indicated by {curly brackets} in the server URL.

Send button

Executes the request by creating a HTTP client with all the information extracted from the view.

Open response in editor

If selected, the response will be opened in the main editing pane.

 **Generate scenario test**

Creates a test scenario file in JSON format, based on the information extracted from the view. The file is then opened in the main editing pane, and can be used to **Run OpenAPI Test Scenario.** *(on page 2808)*

Response area

Initially this area is empty. After using the **Send** button, it presents the message received from the server in response to the request. The expected content type of the message is JSON. The response status and possible errors that may occur are presented right below this area. The status has a green foreground for successful requests and a red foreground otherwise.

For more information about OpenAPI editing, testing, and documenting, watch our webinar:

https://www.youtube.com/embed/gKdabeh49Qk

Generating OpenAPI Documentation

Oxygen XML Editor includes a tool for generating documentation for *OpenAPI* 3.0, or 3.1 documents in either JSON or YAML format, including annotations and cross references. The documentation displays information about the servers, paths, components and tags defined in the OpenAPI documents and you can choose whether the output is presented in HTML (with various sections, hyperlinks, and filtering options), DITA, or PDF.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **OpenAPI Documentation Generator** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

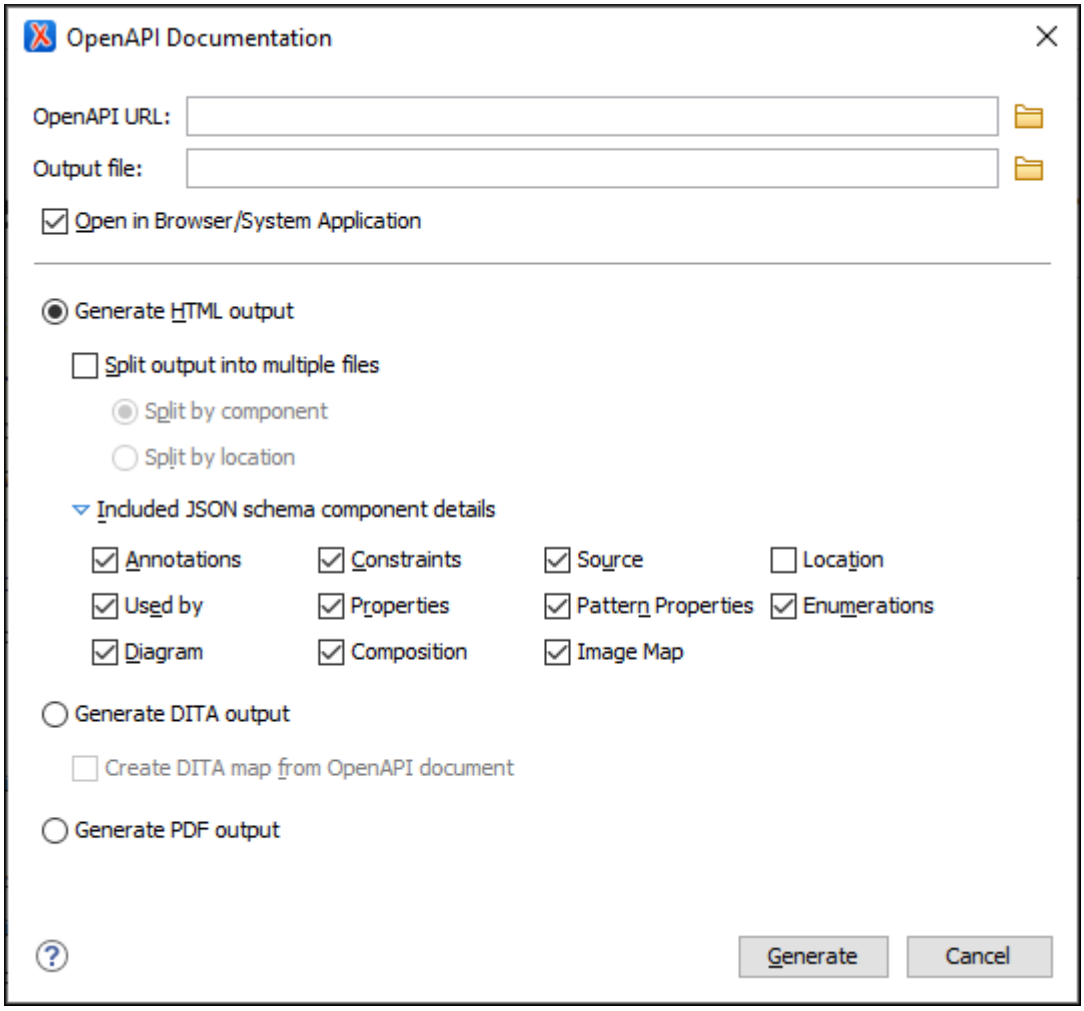
Result: The **OpenAPI Documentation** dialog box is now available and can be selected from the **Tools > Generate Documentation** menu.

Generating OpenAPI Documentation

To generate OpenAPI documentation, select **OpenAPI Documentation** from the **Tools > Generate Documentation** menu. This opens a dialog box where you can specify the location of the OpenAPI file and the output file, as well as the type of output to generate.

This tool requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor presents a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **OpenAPI Documentation** action will invoke the tool.

Figure 637. OpenAPI Documentation Dialog Box



The **OpenAPI Documentation** dialog box includes the following fields and options:

OpenAPI URL

The URL of the OpenAPI file (it can be in either JSON or YAML format). You can specify the path by using the text field or the browsing button ( ).

Output file

The path to the folder where the generated file(s) will be saved.

Generate HTML output

Choose this option to generate the output in HTML format.

Split output into multiple files

If selected, the application splits the output into multiple files. You can choose between splitting them by **component** name or **location**.

Included JSON schema component details

This section can be used to specify whether or not details about the following components that belong to internal or imported schemas are shown in the generated documentation:

- **Annotations** - Displays the annotations (title, description) for each component (property or definition).
- **Constraints** - Displays the schema constraints for each component, according to its type.
- **Source** - Displays the text schema source for each component.
- **Location** - Displays the schema location for each component.
- **Used By** - Displays the list of all the components that reference the current definition.
- **Properties** - Displays the `properties` of an Object Schema.
- **Pattern Properties** - Displays the `patternProperties` of an Object Schema.
- **Enumerations** - Displays the enumerated values, if specified in the schema.
- **Diagram** - Displays the diagram image for each component. The diagrams are generated according to the options specified in the **Schema Design** preferences page *(on page 206)*. Diagrams are also generated for components within schemas from referenced files.
- **Composition** - Displays the `oneOf`, `anyOf`, and `allOf` compositors that are used for combining schemas.

Generate DITA output

Choose this option to generate the output in DITA format.

Create DITA map from OpenAPI document

If selected, the application generates a DITA map with referenced topics based on the input OpenAPI document.

Generate PDF output

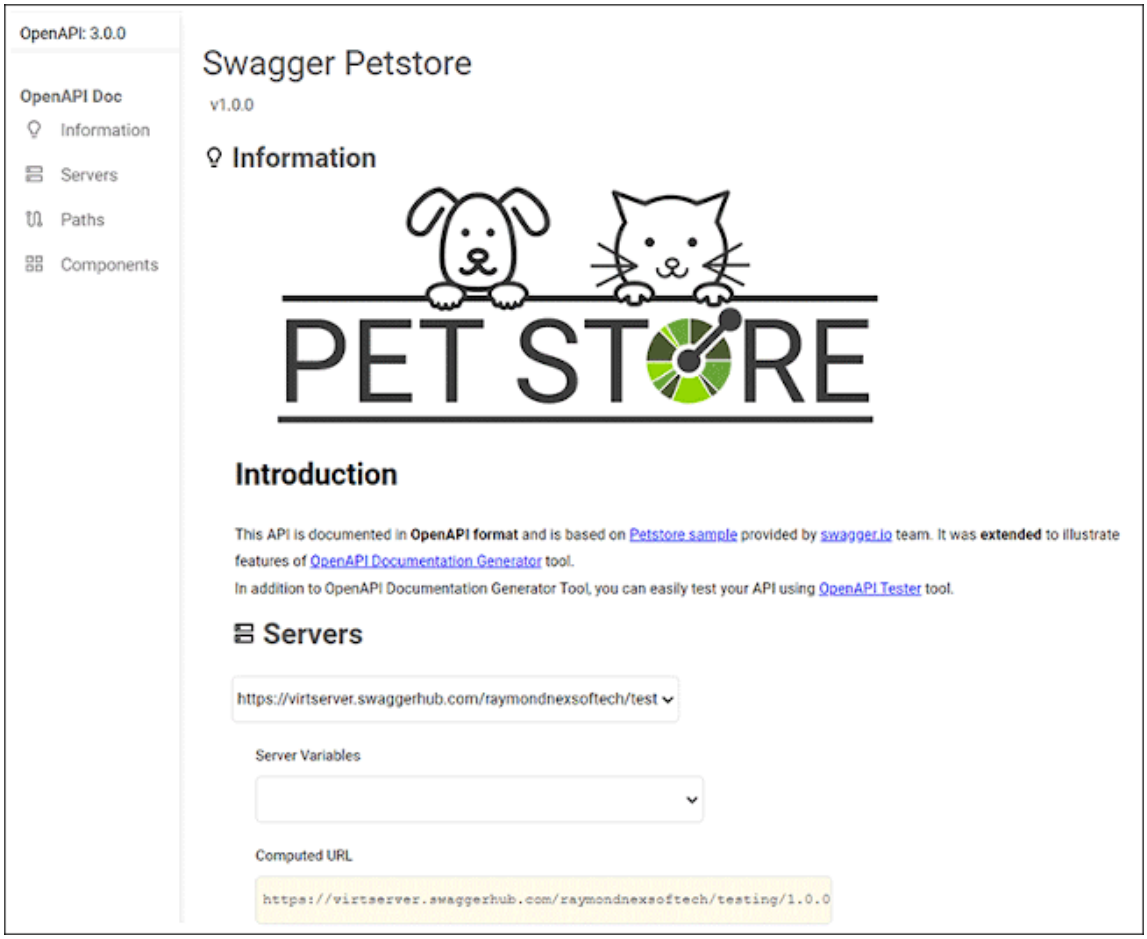
Choose this option to generate the output in PDF format.

Click the **Generate** button to generate the OpenAPI documentation.

Generated OpenAPI Documentation in HTML Format

When generating the OpenAPI documentation in HTML format, it is presented in the browser with various sections, hyperlinks, and options.

Figure 638. OpenAPI Documentation Example



The generated documentation includes a Table of Contents on the left pane with links to particular sections in the right pane. You can collapse or expand details by using the **Collapse** or **Expand** buttons.

https://www.youtube.com/embed/gKdabeh49Qk

JSON Schema Validator

Oxygen XML Editor offers an add-on that contributes a JSON schema validator engine that can be used for validating JSON documents against version 2020-12 JSON schemas. The validation engine is based on the *json-sKema* library (a project in active development).

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **JSON Schema Validator (json-sKema)** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: When creating a JSON validation scenario *(on page 1134)*, you can choose **JSON Schema Validator (json-sKema)** for the validation engine.

Others

DocBook Checker Add-on

Oxygen XML Editor offers an add-on that allows you to validate DocBook files. It reports issues such as broken internal and external links, problems with images, or profiling conditions that conflict with profiling preferences.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

> **Note:**
> If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **DocBook Checker** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: A **Check DocBook for Completeness** action will now be available on the toolbar and in the contextual menu. This action opens a dialog box that offers various validation options for running a completeness check on the current DocBook document.

For more information, see the details for this **DocBook Checker** add-on in GitHub.

CGM Image Support Add-on

Oxygen XML Editor offers an add-on that provide experimental support for CGM 1.0 images. To allow the rendering of CGM images in **Author** mode, the **Oxygen CGM support** add-ons need to be installed in Oxygen XML Editor.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install the **Oxygen CGM support** add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select the **Oxygen CGM support** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: You should be able to see CGM images in **Author** mode.

For more information, see the details about this **CGM Support** add-on in GitHub.

20.

Tools

Oxygen XML Editor includes a variety of helpful tools to help you accomplish XML-related tasks. This section presents many of those tools. These tools are available in the **Tools** menu and some of them can be launched through keyboard shortcuts or command-line scripts.

Refactoring XML Documents

In the life cycle of XML documents there are instances when the XML structure needs to be changed to accommodate various needs. For example, when an associated schema is updated, an attribute may have been removed, or a new element added to the structure.

These types of situations cannot be resolved with a traditional *Find/Replace* tool, even if the tool accepts regular expressions. The problem becomes even more complicated if an XML document is computed or referenced from multiple modules, since multiple resources need to be changed.

To assist you with these types of refactoring tasks, Oxygen XML Editor includes a specialized **XML Refactoring** tool that helps you manage the structure of your XML documents.

XML Refactoring Tool

The **XML Refactoring** tool is presented in the form of an easy to use wizard that is designed to reduce the time and effort required to perform various structure management tasks. For example, you can insert, delete, or rename an attribute in all instances of a particular element that is found in all documents within your project.

To access the tool, select the  **XML Refactoring** action from one of the following locations:

- The **Tools** menu.
- The **Refactoring** submenu from the contextual menu in the **Project** view *(on page 413)*.
- The **Refactoring** submenu from the contextual menu in the **DITA Maps Manager** view *(on page 3073)*.

Note:
The built-in refactoring operations are also available from the **Refactoring** submenu in the contextual menu of **Author** or **Text** mode. This is useful because by selecting the operations from the contextual menu, Oxygen XML Editor considers the editing context to skip directly to the wizard page of the appropriate operation and to help you by preconfiguring some of the parameter values. For your convenience, the last 5 operations that were finished *(on page 2743)* or previewed *(on page 2743)* also appear in the **Refactoring** submenu of the contextual menu in the **Project** view and the **DITA Maps Manager**.

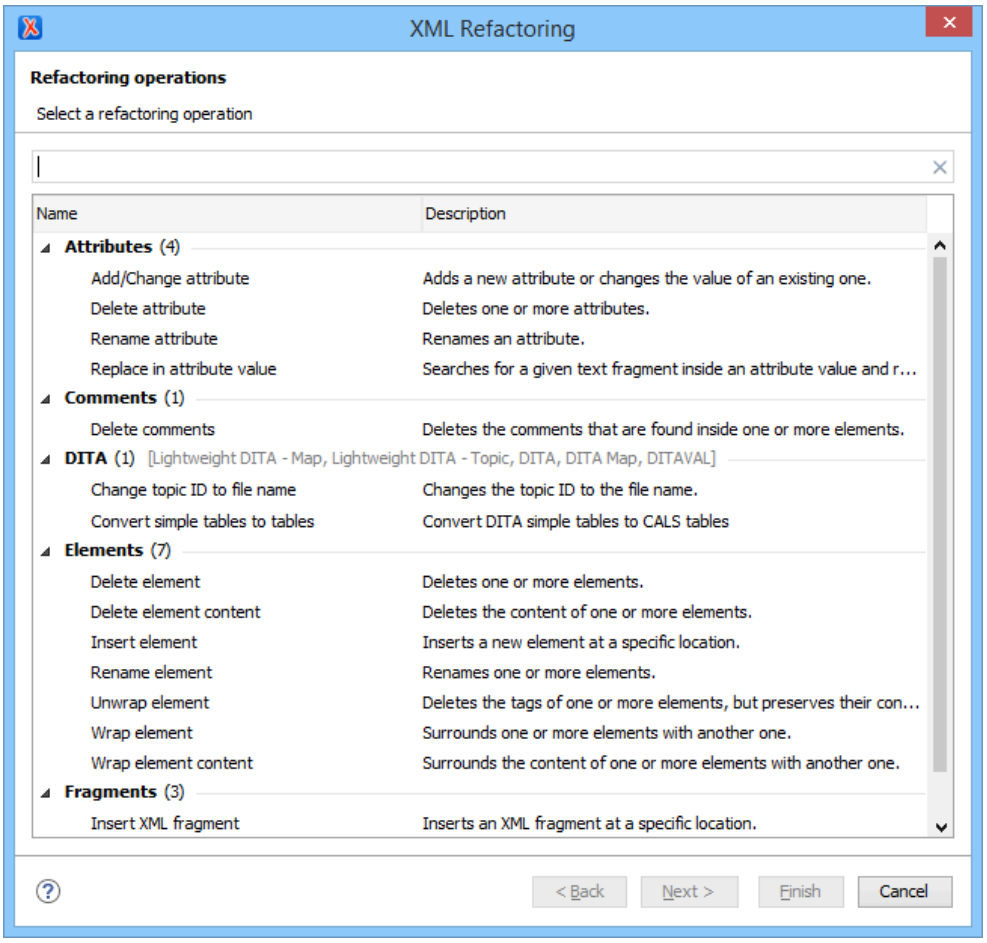
XML Refactoring Wizard

The XML Refactoring tool includes the following wizard pages:

Refactoring operations

The first wizard page presents the available operations, grouped by category. To search for an operation, you can use the filter text box at the top of the page.

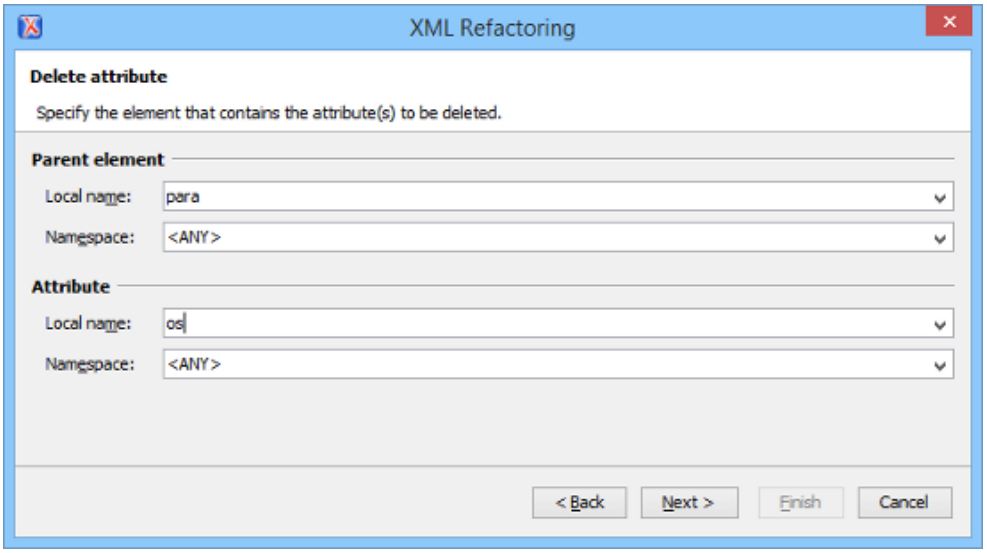
Figure 639. XML Refactoring Wizard



Configure Operation Parameters

The next wizard page allows you to specify the parameters for the refactoring operation.
The parameters are specific to the type of refactoring operation that is being performed. For example, to delete an attribute you need to specify the parent element and the qualified name of the attribute to be removed.

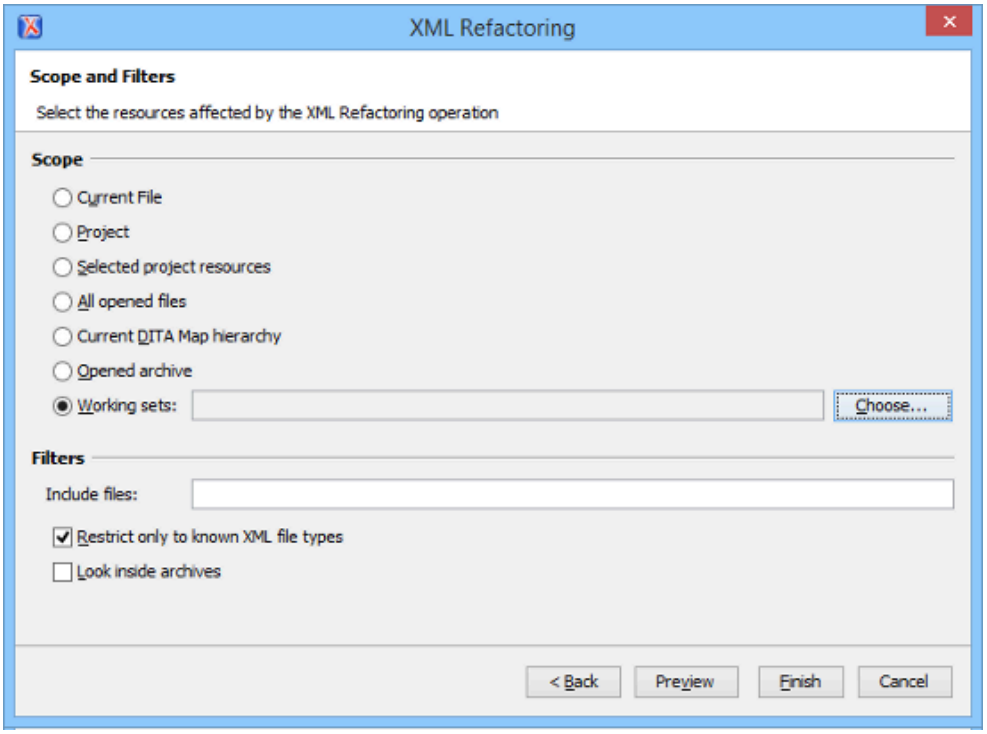
Figure 640. XML Refactoring 2nd Wizard Page (Delete Attribute Operation)



Scope and Filters

The last wizard page allows you to select the set of files that represent the input of the operation.

Figure 641. XML Refactoring - Scope and Filters Wizard Page



Scope section

You can specify the scope for the operation by selecting from predefined resource sets or you can define your own set of resources by creating a *working set (on page 3425)* (select **Working sets** and click the **Choose** button to the right). If you select **Project**, all files attached to the current project will be used for the scope of the operation. If you select **Current DITA Map hierarchy**, the current DITA map

that is open in the DITA Maps Manager along with all of its referenced topics and submaps (and topics referenced in those submaps) are used for the scope.

Filters

The **Filters** section includes the following options:

- **Include files** - Allows you to filter the selected resources by using a file pattern. For example, to restrict the operation to only analyze build files you could use `build*.xml` for the file pattern.
- **Restrict only to known XML file types** - When selected, only resources with a known XML file type will be affected by the operation.
- **Look inside archives** - When selected, the resources inside archives will also be affected.

Preview

You can use the **Preview** button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

Finish

After clicking the **Finish** button, the operation will be processed and Oxygen XML Editor provides no automatic means for reverting the operations. Any **Undo** action will only revert changes on the current document.

Troubleshooting:
If an operation fails, a notification will be displayed in the **Results** panel with some information about the error. For example, if the operation was invoked on a read-only resource, the error will indicate that a read-only file cannot be converted.

Tip:
If an operation takes longer than expected you can use the **Stop** button in the progress bar to cancel the operation.

Restriction:
XML refactoring operations cannot preserve CDATA sections. If your document contains XML CDATA sections, the refactoring operations will convert them to plain text nodes.

Built-in Refactoring Operations

The XML Refactoring tool includes a variety of built-in operations that can be used for common refactoring tasks. They are grouped by category in the **Refactoring operations** wizard page. You can also access the operations from the **Refactoring** submenu in the contextual menu of **Author** or **Text** mode. The operations

are also grouped by category in this submenu. When selecting the operations from the contextual menu, Oxygen XML Editor considers the editing context to get the names and namespaces of the current element or attribute, and uses this information to preconfigure some of the parameter values for the selected refactoring operation.

Tip:
Each operation includes a link in the lower part of the wizard that opens the **XML / XSLT-XQuery / XPath** preferences page where you can configure XPath options and declare namespace prefixes.

The following built-in operations are available:

Refactoring Operations for *Attributes*

Add/Change attribute

Use this operation to change the value of an attribute or insert a new one. This operation allows you to specify the following parameters:

Parent element section

Element

The parent element of the attribute to be changed, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Attribute section

Local name

The local name of the affected attribute.

Namespace

The namespace of the affected attribute.

Value

The value for the affected attribute.

Options section

You can choose between one of the following options for the **Operation mode**:

Add the attribute in the parent elements where it is missing

Adds the attribute to all instances of the specified parent element.

Change the value in the parent elements where the attribute already exists

Replaces the value of the already existing attribute in all instance of the specified parent element.

Both

Adds the attributes to the instances where it is missing and replaces the value in instances where the attribute already exists.

Convert attribute to element

Use this operation to convert a specified attribute to an element. This operation allows you to specify the following parameters:

Parent element section

Element

The parent element of the attribute to be converted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Attribute section

Local name

The local name of the affected attribute.

Namespace

The namespace of the affected attribute.

New element section

Local name

The local name of the new element.

Namespace

The namespace of the new element.

Delete attribute

Use this operation to remove one or more attributes. This operation requires you to specify the following parameters:

Element

The parent element of the attribute to be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Attribute

The name of the attribute to be deleted.

Rename attribute

Use this operation to rename an attribute. This operation requires you to specify the following parameters:

Element

The parent element of the attribute to be renamed, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Attribute

The name of the attribute to be renamed.

New local name

The new local name of the attribute.

Replace in attribute value

Use this operation to search for a text fragment inside an attribute value and change the fragment to a new value. This operation allows you to specify the following parameters:

Target attribute section

Element

The parent element of the attribute to be modified, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Attribute

The name of the attribute to be modified.

Find / Replace section

Find

The text fragments to find. You can use Perl-like regular expressions.

Replace with

The text fragment to replace the target with. This parameter can bind regular expression capturing groups (`$1`, `$2`, etc.) from the find pattern.

Refactoring Operations for *Comments*

Delete comments

Use this operation to delete comments from one or more elements. This operation requires you specify the following parameter:

Element

The target element (or elements) that will have comments deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Note:
Comments that are outside the root element will not be deleted because the *serializer* preserves the content before and after the root.

Refactoring Operations for *DITA* Topics

Change topic ID to file name

Use this operation to change the ID of a topic to be the same as its file name.

Convert CALS tables to simple tables

Use this operation to convert DITA CALS tables to simple tables.

Convert DITA 1.3 Maps and Topics to DITA 2.0

Use this operation to convert topics and maps that adhere to the DITA 1.3 standard to the DITA 2.0 standard.

- Changes DOCTYPE declarations and XML Schema/Relax NG schema references.
- DITA Map changes:
  - Removes the `@lockmeta` attribute.
  - Removes the `<topicset>` and `<topicsetref>` elements.
  - Removes the `<anchor>` and `<anchorref>` elements and the `@anchorref` attribute.
  - Migrates the `@navtitle` attribute as a `<navtitle>` element.
  - Migrates the `@title` attribute as a `<title>` element.
  - Converts the `@copy-to` attribute to a `<resourceid>` element.
  - Replaces the `@print` attribute with an `@deliveryTarget` attribute.
  - Convert topicmeta `<linktext>` to `<linktitle>`.
  - Removed `<hasInstance>`, `<hasKind>`, `<hasNarrower>`, `<hasPart>`, `<hasRelated>`, and `<relatedSubjects>` from subject scheme relationship tables in subject scheme, including `<subjectRelTable>`, `<subjectRelHeader>`, `<subjectRel>`, and `<subjectRole>`.
- DITA task changes:
  - Converts the `<substep>` element to a `<step>` element.
  - Converts the `<substeps>` element to a `<steps>` element.
- DITA topic changes:
  - Removes the `@type` attribute with the value `fastpath`.
  - Converts the `@alt` attribute to an `<alt>` element.
  - Replaces the `<index-sort-as>` element with a `<sort-as>` element.
  - Removes the `<itemgroup>` element.
  - Moves the contents of the `<titlealts>` element inside the `<prolog>`.
  - Removes the `@domains` attribute.
  - Renames `<sectiondiv>` to `<div>`.
  - Remove `@query` attribute from `<link>` element.

- Remove `@specentry` attribute from `<stentry>` element.

  Remove the `@spectitle` attribute.

Convert conrefs to conkeyrefs

Use this operation to convert `@conref` attributes to `@conkeyref` attributes. For more information and instructions for using this operation, see Converting Conrefs to Conkeyrefs *(on page 3222)*.

Convert Nested Topics to New Topics (Available from the contextual menu of editable maps/nodes in the DITA Maps Manager *(on page 3073)*)

Use this operation on topics that contain nested `<topic>` elements to convert each nested topic to a new topic. Also, the new topics are added in the **DITA Maps Manager** as the first child topics of the original topic.

Convert Sections to New Topics (Available from the contextual menu of editable maps/nodes in the DITA Maps Manager *(on page 3073)*)

Use this operation on topics that contain multiple sections to convert each section to a new topic. Also, the new topics are added in the **DITA Maps Manager** as the first child topics of the original topic.

Convert simple tables to CALS tables

Use this operation to convert DITA simple tables to CALS tables.

Convert to Concept

Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept). For more information, see Converting DITA Topics to Another Type *(on page 3147)*.

Convert to General Task

Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). For more information, see Converting DITA Topics to Another Type *(on page 3147)*.

Convert to Reference

Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference). For more information, see Converting DITA Topics to Another Type *(on page 3147)*.

Convert to Task

Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task). For more information, see Converting DITA Topics to Another Type *(on page 3147)*.

Convert to Topic

Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic). For more information, see Converting DITA Topics to Another Type *(on page 3147)*.

Convert to Troubleshooting

Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting). For more information, see Converting DITA Topics to Another Type *(on page 3147)*.

Rename Key

Use this operation to rename a key. It also updates all references to it.

Note:
It does not work on DITA 1.3 key scopes.

Generate IDs

Use this operation to automatically generate unique IDs for elements.

Scope and Filters:

All of the DITA refactoring actions allow you to choose a scope for the operation and some filters:

Scope

Select from a variety of options to define the scope that will have resources affected by the operation. For example, you can choose to affect all resources in the **Project**, **All opened files**, **Current DITA map hierarchy**, or just the **Current file**.

Filters section

Include files

Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as ***** or **?**).

Restrict to known XML file types only

Excludes non-XML file types from the operation.

Look inside archives

If this option is selected, the scope of the operation will include files inside archives.

Refactoring Operations for *DITA* Maps

Convert DITA Bookmap to Map

Convert a DITA bookmap to a DITA map.

Convert DITA Map to Bookmap

Convert a DITA map to a DITA bookmap.

Change or remove profiling attribute value

Change or remove a value from a DITA profiling attribute. A profiling attribute can have multiple values, separated by spaces (e.g. for `platform="windows redhat"`, you can change the current `redhat` value to `linux`). Select the name of the profiling attribute, the current value to replace, and the new value. If the new value is left empty, the current value is removed from the profiling attribute. The new value is modified and reflected in DITA maps, DITA topics, and DITAVAL files.

Define keys for all topic references

This refactoring action is useful for converting links inside a DITA project from direct to indirect key-based addressing. When applied on DITA resources from your project (DITA maps and topics), this refactoring action defines keys for all of a DITA map's topic references based on the referenced file name and converts each direct reference to a key reference in each DITA topic. If a topic references already has keys defined, the action does not define new ones. Inside the DITA topics, whenever there is a link element (`<xref>` or `<link>`) with a direct reference to another DITA topic or an element with a `@conref`, the action attempts to convert them to indirect key-based addressing. The refactoring action may introduce linking errors or create duplicate keys so it is advised to run the **Validate and check for completeness** action from the **DITA Maps Manager** toolbar to manually fix those problems. You can enable the **Report duplicate keys** checkbox to also report any keys that are defined more than once.

Scope and Filters:

All of the DITA refactoring actions allow you to choose a scope for the operation and some filters:

Scope

Select from a variety of options to define the scope that will have resources affected by the operation. For example, you can choose to affect all resources in the **Project**, **All opened files**, **Current DITA map hierarchy**, or just the **Current file**.

Filters section

Include files

Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as ***** or **?**).

Restrict to known XML file types only

Excludes non-XML file types from the operation.

Look inside archives

If this option is selected, the scope of the operation will include files inside archives.

Refactoring Operations for *Elements*

Delete element

Use this operation to delete elements. This operation requires you to specify the following parameter:

Element

The target element to be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Delete element content

Use this operation to delete the content of elements. This operation requires you to specify the following parameter:

Element

The target element whose content is to be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Insert element

Use this operation to insert new elements. This operation allows you to specify the following parameters:

Element section

Local name

The local name of the element to be inserted.

Namespace

The namespace of the element to be inserted.

Location section

XPath

An XPath expression that identifies an existing element to which the new element is relative, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

Position

The position where the new element will be inserted, in relation to the specified existing element. The possible selections in the drop-down menu are: **After**, **Before**, **First child**, or **Last child**.

Rename element

Use this operation to rename elements. This operation requires you to specify the following parameters:

Target elements (XPath)

The target elements to be renamed, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

New local name

The new local name of the element.

Unwrap element

Use this operation to remove the surrounding tags of elements, while keeping the content unchanged. This operation requires you to specify the following parameter:

Target elements (XPath)

The target elements whose surrounding tags will be removed, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

Wrap element

Use this operation to surround elements with element tags. This operation allows you to specify the following parameters:

Target elements (XPath)

The target elements to be surrounded with tags, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

Wrapper element section

Local name

The local name of the *Wrapper element*.

Namespace

The namespace of the *Wrapper element*.

Wrap element content

Use this operation to surround the content of elements with element tags. This operation allows you to specify the following parameters:

Target elements (XPath)

The target elements whose content will be surrounded with tags, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

Wrapper element section

Local name

The local name of the *Wrapper element* that will surround the content of the target.

Namespace

The namespace of the *Wrapper element* that will surround the content of the target.

Refactoring Operations for *Fragments*

Insert XML fragment

Use this operation to insert an XML fragment. This operation allows you to specify the following:

XML Fragment

The XML fragment to be inserted.

Location section

XPath

An XPath expression that identifies an existing element to which the inserted fragment is relative, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

Position

The position where the fragment will be inserted, in relation to the specified existing element. The possible selections in the drop-down menu are: **After**, **Before**, **First child**, or **Last child**.

Replace element content with XML fragment

Use this operation to replace the content of elements with an XML fragment. This operation allows you to specify the following parameters:

Target elements (XPath)

The target elements whose content will be replaced, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

XML Fragment

The XML fragment with which to replace the content of the target element.

Replace element with XML fragment

Use this operation to replace elements with an XML fragment. This operation allows you to specify the following parameters:

Target elements (XPath)

The target elements to be replaced, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

XML Fragment

The XML fragment with which to replace the target element.

Refactoring Operations for *JATSKit*

Add BITS DOCTYPE - NLM/NCBI Book Interchange 2.0

Use this operation to add an NLM 'BITS' 2.0 DOCTYPE declaration.

Add Blue DOCTYPE - NISO JATS Publishing 1.1

Use this operation to add a JATS 'Blue' 1.1 DOCTYPE declaration.

Normalize IDs

Use this operation to normalize assigned IDs and assigned IDs to elements that are missing them.

All of these *JATSKit* refactoring actions allow you to choose a scope for the operation and some filters:

Scope

Select from a variety of options to define the scope for the resources that will be affected by the operation. For example, you can choose to affect all resources in the **Project**, **All opened files**, or just the **Current file**.

Filters section

Include files

Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as ***** or **?**).

Restrict to known XML file types only

Excludes non-XML file types from the operation.

Look inside archives

If this option is selected, the scope of the operation will include files inside archives.

Refactoring Operations for *Processing Instructions*

Accept all tracked changes, remove all Oxygen-specific comments and highlights

Use this operation to accept all application-specific tracked changes (from elements and attributes) or remove all application-specific comments or highlights. There are several options to choose from:

Accept all tracked changes

Accepts all application-specific tracked changes (from elements and attributes).

Remove comments

Removes all application-specific comments.

Remove highlights

Removes all application-specific highlights.

Delete processing instructions

Use this operation to delete all processing instructions that have a certain target name from the processed documents. This operation requires you to specify the following parameter:

Processing instruction target

The target name of the processing instructions to delete.

Note:
Processing instructions that are outside the root element are not deleted because the *serializer* preserves the content before and after the root.

Refactoring Operations for *Publishing Template*

These operations are for those who use *Oxygen Publishing Templates* for WebHelp Responsive output customization.

Migrate HTML Page Layout Files to v21

Use this operation to convert custom HTML page layout files *(on page 1677)* that are included in a custom Publishing Template that was created in Oxygen XML Editor version 20.0 or 20.1 so that they will be compatible with Oxygen XML Editor version 21.0.

Migrate HTML Page Layout Files to v22

Use this operation to convert custom HTML page layout files *(on page 1677)* that are included in a custom Publishing Template that was created in Oxygen XML Editor versions 20.0 - 21.1 so that they will be compatible with Oxygen XML Editor version 22.0.

Update HTML Pages

Attention:
This operation is only used by Oxygen XML Editor and should not be used manually.

Additional Notes:

- There are some operations that allow `<ANY>` for the **local name** and **namespace** parameters. This value can be used to select an element or attribute regardless of its local name or namespace. Also, the `<NO_NAMESPACE>` value can be used to select nodes that do not belong to a namespace.
- Some operations have parameters that accept XPath expressions to match elements or attributes. In these XPath expressions you can only use the prefixes declared in the **Options > Preferences > XML > XSLT-XQUERY > XPath** *(on page 267)* page. This preferences page can be easily opened by clicking the link in the note (**Each prefix used in an XPath expression must be declared in the Default prefix-namespace mappings section**) at the bottom of the **Configure Operation Parameters** wizard page.

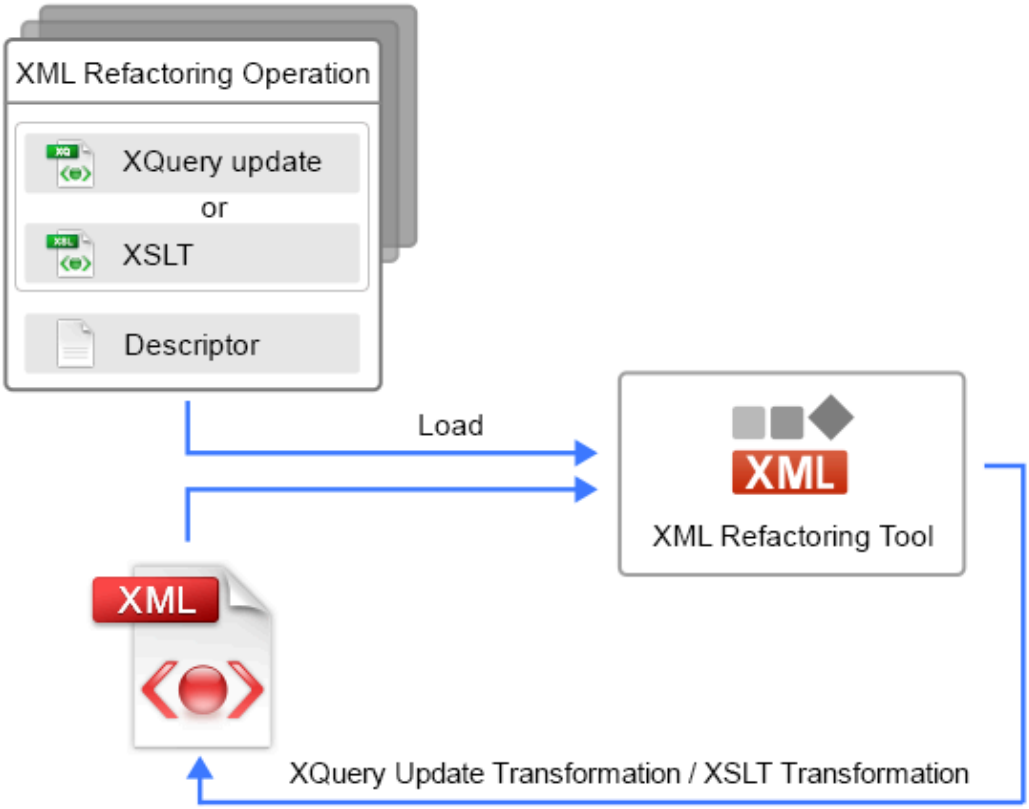
Custom Refactoring Operations

While Oxygen XML Editor includes a variety of built-in XML refactoring operations to help you accomplish particular tasks, you can also create custom operations according to your specific needs. For example, you could create a custom refactoring operation to convert an attribute to an element and insert the element as the first child of the parent element.

An XML Refactoring operation is defined as a pair of resources:

- An *XQuery Update script* or *XSLT stylesheet* that Oxygen XML Editor will run to refactor the XML files.
- An *XML Operation Descriptor* file that contains information about the operation (such as the name, description, and parameters).

Figure 642. Diagram of an XML Refactoring Operation



All the defined custom operations are loaded by the **XML Refactoring Tool** and presented in the **Refactoring Operations** wizard page *(on page 853)*, along with the built-in operations.

After the user chooses an operation and specifies its parameters, Oxygen XML Editor processes an XQuery Update or XSLT transformation over the input file. This transformation is executed in a **safe mode**, which implies the following:

- When loading the document:
  - The **XInclude** mechanism is disabled. This means that the resources included by using XInclude will not be visible in the transformation.
  - The DTD entities will be processed without being expanded.
  - The associated DTD will be not loaded, so the default attributes declared in the DTD will not be visible in the transformation.
- When saving the updated XML document:
  - The `DOCTYPE` will be preserved.

    Note:
    This can be changed using Saxon extension functions in XSLT *(on page 886)*.

  - The DTD entities will be preserved as they are in the original document when the document is saved.

- The attribute values will be kept in their original form without being normalized.
- The spaces between attributes are preserved. Basically, the spaces are lost by a regular XML serialization since they are not considered important.

The result of this transformation overrides the initial input file.

Note:
To achieve some of the previous goals, the XML Refactoring mechanism adds several attributes that are interpreted internally. The attributes belong to the `http://www.oxygenxml.com/ns/xmlRefactoring/additional_attributes` namespace. These attributes should not be taken into account when processing the input XML document since they are discarded when the transformed document is serialized.

Restriction:
Comments or *processing instructions* that are in any node before or after the root element cannot be modified by an XML Refactoring operation. In other words, XML Refactoring operations can only be applied on the root element and the nodes inside it. However, as a work around to this limitation, you can use Saxon extension functions and the XSLT stylesheet method *(on page 886)* to implement the new custom XML refactoring operation.

Creating a Custom Refactoring Operation

To create a custom refactoring operation, follow these steps:

1. Create an XQuery Update script *(on page 876)* or XSLT stylesheet file *(on page 881)*.
2. Create an XML refactoring operation descriptor file, that references the above script, as explained in these sections: Example descriptor file for an XQuery Update script *(on page 879)* or Example descriptor file for an XSLT stylesheet *(on page 884)*.
3. Store both files in one of the locations that Oxygen XML Editor *(on page 888)* scans when loading the custom operations.

   Result: Once you run the **XML Refactoring** tool again, the custom operation appears in the **Refactoring Operations** wizard page *(on page 853)*.

Related information
Storing and Sharing Refactoring Operations *(on page 888)*

Custom Refactoring Script

The first step in creating a custom refactoring operation is to create an XQuery Update script *(on page 876)* or XSLT stylesheet *(on page 881)* that is needed to process the refactoring operations. The easiest way to create

this script file is to use the **New** document wizard to create a new **XQuery** or **XSLT** file and you can use the XQuery method example *(on page 876)* or XSLT method example *(on page 881)* to help you with the content.

There are cases when it is necessary to add parameters in the XQuery script *(on page 876)* or XSLT stylesheet *(on page 881)*. For instance, if you want to rename an element, you may want to declare an external parameter associated with the name of the element to be renamed. To allow you to specify the value for these parameters, they need to be declared in the *refactoring operation descriptor file* that is associated with this operation.

Note:
The XQuery Update processing is disabled by default in Oxygen XML Editor. Thus, if you want to create or edit an XQuery Update script you have to enable this mechanism by creating an XQuery transformation scenario *(on page 1588)* and choose **Saxon EE** as the transformation engine. Also, you need to make sure the **Enable XQuery update** option is selected in the Saxon processor advanced options *(on page 1525)*.

Note:
If you are using an XSLT file, XPath expressions that are passed as parameters will automatically be rewritten to conform with the mapping of the namespace prefixes declared in the **XML /XSLT-XQuery / XPath** preferences page *(on page 267)*.

The next step in creating a custom refactoring operation is to create an **XML Refactoring Operation Descriptor** file contains the path to the XQuery Update script *(on page 879)* or XSLT stylesheet *(on page 884)*.

Related Information:
XQuery Update Script for Creating a Custom Operation *(on page 876)*
XSLT Stylesheet for Creating a Custom Operation *(on page 881)*

Custom Refactoring Operation Descriptor File

The second step in creating a custom refactoring operation is to create an operation descriptor file. The easiest way to do this is to use the **New** document wizard and choose the **XML Refactoring Operation Descriptor** template.

Introduction to the Descriptor File

This descriptor file root element specifies required attributes to define the operation `@name`, `@description`, and `@id` which are necessarily when loading an XML Refactoring operation. It also contains the path to the XQuery Update script *(on page 876)* or XSLT stylesheet *(on page 881)* that is associated with the particular operation through the `<script>` element.

The optional `@filesFilter` attribute can be specified to filter the resources by using a file pattern or list of file patterns separated by a comma (for example: `filesFilter="*.dita, *.xml"`). When set, its value is

automatically populated in the **Include files** field within the **Scope and Filters** wizard page *(on page 855)* as a default value.

You can specify a *category* for your custom operations to logically group certain operations. The `<category>` element is optional and if it is not included in the descriptor file, the default name of the category for the custom operations is *Other operations*.

The descriptor file is edited and validated against the following schema: `frameworks/xml_refactoring/operation_descriptor.xsd`.

Declaring Parameters in the Descriptor File

If the XQuery Update script or XSLT stylesheet includes parameters, they should be declared in the **parameters** section of the descriptor file. All the parameters specified in this section of the descriptor file will be displayed in the **XML Refactoring** tool within the **Configure Operation Parameters** wizard page *(on page 854)* for that particular operation.

The value of the first `<description>` element in the `<parameters>` section will be displayed at the top of the **Configure Operation Parameters** wizard page *(on page 854)*.

To declare a parameter, specify the following information:

- **label** - This value is displayed in the user interface for the parameter.
- **name** - The parameter name used in the XQuery Update script or XSLT stylesheet and it should be the same as the one declared in the script.
- **type** - Defines the type of the parameter and how it will be rendered. There are several types available:
  - **TEXT** - Generic type used to specify a simple text fragment.
  - **XPATH** - Type of parameter whose value is an XPATH expression. For this type of parameter, Oxygen XML Editor will use a text input with corresponding content completion and syntax highlighting.

Note:
The value of this parameter is transferred as plain text to the XQuery Update or XSLT transformation without being evaluated. You should evaluate the XPath expression inside the XQuery Update script or XSLT stylesheet. For example, you could use the `saxon:evaluate` Saxon extension function.

Note:
A relative XPath expression is converted to an absolute XPath expression by adding `//` before it (`//XPathExp`). This conversion is done before transferring the XPath expression to the XML refactoring engine.

Note:
When writing XPath expressions, you can only use prefixes declared in the **Options > Preferences > XML > XSLT-XQuery > XPath** *(on page 267)* options page.

- **NAMESPACE** - Used for editing namespace values.
- **REG_EXP_FIND** - Used when you want to match a certain text by using Perl-like regular expressions.
- **REG_EXP_REPLACE** - Used along with `REG_EXP_FIND` to specify the replacement string.
- **XML_FRAGMENT** - This type is used when you want to specify an XML fragment. For this type, Oxygen XML Editor will display a text area specialized for inserting XML documents.
- **NC_NAME** - The parameter for `NC_NAME` values. It is useful when you want to specify the local part of a *QName (on page 3423)* for an element or attribute.
- **BOOLEAN** - Used to edit boolean parameters.
- **TEXT_CHOICE** - It is useful for parameters whose value should be from a list of possible values. Oxygen XML Editor renders each possible value as a radio button option.

- **optional** - Specifies whether the parameter is optional or required. For optional parameters, the end user is not required to fill in a value in the XML refactoring wizard.
- **description** - The description of the parameter. It is used by the application to display a tooltip when you hover over the parameter.
- **possibleValues** - Contains the list with possible values for the parameter and you can specify the default value, as in the following example:

```
<possibleValues onlyPossibleValuesAllowed="true">
    <value name="before">Before</value>
    <value name="after" default="true">After</value>
    <value name="firstChild">First child</value>
    <value name="lastChild">Last child</value>
</possibleValues>
```

On a `<value>`, you can specify the `@default` attribute with the value `true` to mark it as the default presented value in the XML refactoring wizard. The text specified inside the `<value>` element is displayed as placeholder default text in the text entry box. If the dialog box is accepted with the placeholder text in place, the `@name` attribute value is passed to the refactoring script. Example:

```
<value name="my-actual-default-value" default="true">[default displayed]</value>
```

Specialized Parameters to Match Elements or Attributes

If you want to match elements or attributes, you can use some specialized parameters, in which case Oxygen XML Editor will propose all declared elements or attributes based on the schema associated with the currently edited file. The following specialized parameters are supported:

elementLocation

This parameter is used to match elements. For this type of parameter, the application displays a text field where you can enter the element name or an XPath expression. The text from the `@label` attribute is displayed in the application as the label of the text field. The `@name` attribute is used to specify the name of the parameter from the XQuery Update script or XSLT stylesheet. If the value of the `@useCurrentContext` attribute is set to **true**, the element name from the cursor position is used as proposed values for this parameter.

Example of an `<elementLocation>`:

```
<elementLocation name="elem_loc" useCurrentContext="false">
                <element label="Element location">
                    <description>Element location description.</description>
                </element>
</elementLocation>
```

attributeLocation

This parameter is used to match attributes. For this type of parameter, the application displays two text fields where you can enter the parent element name and the attribute name (both text fields accept XPath expressions for a finer match). The text from the `@label` attributes is displayed in the application as the label of the associated text fields. The `@name` attribute is used to specify the name of the parameter from the XQuery Update script or XSLT stylesheet. The value of this parameter is an XPath expression that is computed by using the values of the expression from the *element* and *attribute* text fields. For example, if `section` is entered for the element and a `title` is entered for the attribute, the XPath expression would be computed as `//section/@title`. If the value of the `useCurrentContext` attribute is set to `true`, the element and attribute name from the cursor position is used as proposed values for the operation parameters.

Example of an `<attributeLocation>`:

```
<attributeLocation name="attr_xpath" useCurrentContext="true">
                <element label="Element path">
                    <description>Element path description.</description>
                </element>
                <attribute label="Attribute" >
                    <description>Attribute path description.</description>
                </attribute>
</attributeLocation>
```

elementParameter

This parameter is used to specify elements by local name and namespace. For this type of parameter, the application displays two combo boxes with elements and namespaces collected from the associated schema of the currently edited file. The text from the `@label` attribute is displayed in the application as label of the associated combo. The `@name` attribute is used to specify the name of the parameter from the XQuery Update script or XSLT stylesheet. If you

specify the `@allowsAny` attribute, the application will propose *<ANY>* as a possible value for the **Name** and **Namespace** combo boxes. You can also use the `@useCurrentContext` attribute and if its value is set to `true`, the element name and namespace from the cursor position is used as proposed values for the operation parameters.

Example of an `<elementParameter>`:

```
<elementParameter id="elemID" useCurrentContext="true">
    <localName label="Name" name="element_localName" allowsAny="true">
        <description>Local name of the parent element.</description>
    </localName>
    <namespace label="Namespace" name="element_namespace" allowsAny="true">
        <description>Local name of the parent element</description>
    </namespace>
</elementParameter>
```

attributeParameter

This parameter is used to specify attributes by local name and namespace. For this type of parameter, the application displays two combo boxes with attributes and their namespaces collected from the associated schema of the currently edited file. The text from the `@label` attribute is displayed in the application as the label of the associated combo box. You can also use the `@useCurrentContext` attribute and if its value is set to `true`, the attribute name and namespace from the cursor position is used as proposed values for the operation parameters.

Note:
An `<attributeParameter>` is dependant upon an `<elementParameter>`. The list of attributes and namespaces are computed based on the selection in the *elementParameter* combo boxes.

Example of an `<attributeParameter>`:

```
<attributeParameter dependsOn="elemID" useCurrentContext="true">
    <localName label="Name" name="attribute_localName">
        <description>The name of the attribute to be converted.</description>
    </localName>
    <namespace label="Namespace" name="attribute_namespace" allowsAny="true">
        <description>Namespace of the attribute to be converted.</description>
    </namespace>
</attributeParameter>
```

Grouping Parameters in the Descriptor File

You can use `<section>` elements to group related parameters in the descriptor file:

```
<section label="Parent element">
  <elementParameter id="elemID">
    <localName label="Name" name="element_localName" allowsAny="true">
      <description>Local name of the parent element.</description>
    </localName>
    <namespace label="Namespace" name="element_namespace" allowsAny="true">
      <description>Local name of the parent element</description>
    </namespace>
  </elementParameter>
</section>
```

Note:
All built-in operations are loaded from the *[OXYGEN_INSTALL_DIR]*`/refactoring` folder.

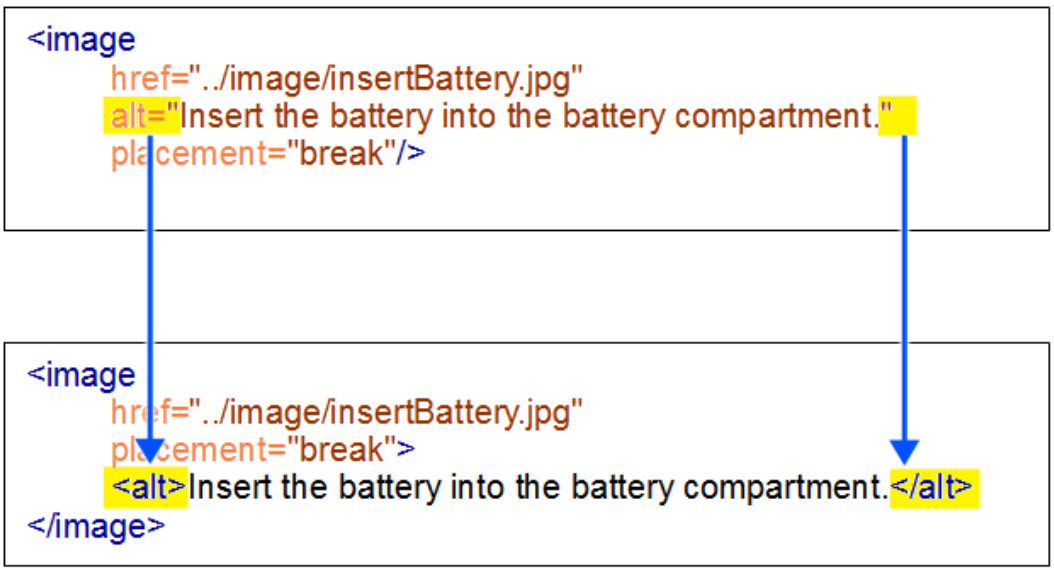
XSLT Stylesheet for Creating a Custom Operation

To demonstrate creating a custom operation, suppose that you have a task where you need to convert an attribute into an element and insert it inside another element. A specific example would be if you have a project with a variety of `<image>` elements where a deprecated `@alt` attribute was used for the description and you want to convert all instances of that attribute into an element with the same name and insert it as the first child of the `<image>` element.

Thus, the task is to convert this attribute into an element with the same name and insert it as the first child of the image element.

Figure 643. Example: Custom XML Refactoring Operation



An XSLT stylesheet can be used to implement the new custom XML refactoring operation. The second requirement is an XML Refactoring operation descriptor file *(on page 2767)* that contains the path to the XSLT stylesheet.

Example of an XSLT Script for Creating a Custom Operation to *Convert an Attribute to an Element*

The XSLT stylesheet does the following:

- Iterates over all elements from the document that have the specified local name and namespace.
- Finds the attribute that will be converted to an element.
- Adds the new element as the first child of the parent element.

```
<?xml version="1.0" encoding="UTF-8"?>

  version="2.0">

  <xsl:import
href="http://www.oxygenxml.com/ns/xmlRefactoring/resources/commons.xsl"/>

  <xsl:param name="element_localName" as="xs:string" required="yes"/>
  <xsl:param name="element_namespace" as="xs:string" required="yes"/>
  <xsl:param name="attribute_localName" as="xs:string" required="yes"/>
  <xsl:param name="attribute_namespace" as="xs:string" required="yes"/>
  <xsl:param name="new_element_localName" as="xs:string" required="yes"/>
```

```
<xsl:param name="new_element_namespace" as="xs:string" required="yes"/>

<xsl:template match="node() | @*">
    <xsl:copy>
        <xsl:apply-templates select="node() | @*"/>
    </xsl:copy>
</xsl:template>
<xsl:template match="//*[xr:check-local-name($element_localName, ., true())
   and
      xr:check-namespace-uri($element_namespace, .)]">

    <xsl:variable name="attributeToConvert"
       select="@*[xr:check-local-name($attribute_localName, ., true())
   and
      xr:check-namespace-uri($attribute_namespace, .)]"/>

    <xsl:choose>
        <xsl:when test="empty($attributeToConvert)">
            <xsl:copy>
                <xsl:apply-templates select="node() | @*"/>
            </xsl:copy>
        </xsl:when>
    <xsl:otherwise>
        <xsl:copy>
            <xsl:for-each select="@*[empty(. intersect $attributeToConvert)]">
                 <xsl:copy-of select="."/>
            </xsl:for-each>
              <!-- The new element namespace -->
              <xsl:variable name="nsURI" as="xs:string">
                  <xsl:choose>
         <xsl:when test="$new_element_namespace eq $xr:NO-NAMESPACE">
                        <xsl:value-of select="''"/>
                    </xsl:when>
                    <xsl:otherwise>
                        <xsl:value-of select="$new_element_namespace"/>
                    </xsl:otherwise>
                  </xsl:choose>
              </xsl:variable>
        <xsl:element name="{$new_element_localName}" namespace="{$nsURI}">
                  <xsl:value-of select="$attributeToConvert"/>
              </xsl:element>
            <xsl:apply-templates select="node()"/>
```

```
        </xsl:copy>
      </xsl:otherwise>
    </xsl:choose>
  </xsl:template>
</xsl:stylesheet>
```

Note:
The XSLT stylesheet imports a module library that contains utility functions and variables. The location of this module is resolved via an *XML Catalog (on page 3425)* set in the XML Refactoring *framework (on page 3420)*.

Example of an Operation Descriptor File That References the XSLT Stylesheet for Creating a Custom Operation to *Convert an Attribute to an Element*

After you have developed the XSLT stylesheet (for example, named `convert-attribute-to-element.xsl`), you have to create an XML Refactoring operation descriptor (for example, named `convert-attribute-to-element.xml`) that references the stylesheet and provides descriptions and possible values for its parameters. This descriptor is used by the application to load the operation details such as name, description, or parameters.

```
<?xml version="1.0" encoding="UTF-8"?>

<refactoringOperationDescriptor
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns="http://www.oxygenxml.com/ns/xmlRefactoring"
 id="convert-attribute-to-element"
 name="Convert attribute to element">
 <description>Converts the specified attribute to an element.
          The new element will be inserted as first child of the attribute's
          parent element.</description>
 <script type="XSLT" href="convert-attribute-to-element.xsl"/>
  <parameters>
   <description>Specify the attribute to be converted to element.</description>
    <section label="Parent element">
     <elementParameter id="elemID">
      <localName label="Name" name="element_localName" allowsAny="true">
       <description>Local name of the parent element.</description>
        </localName>
       <namespace label="Namespace" name="element_namespace" allowsAny="true">
         <description>Local name of the parent element</description>
       </namespace>
     </elementParameter>
    </section>
```

```
    <section label="Attribute">
     <attributeParameter dependsOn="elemID">
      <localName label="Name" name="attribute_localName">
       <description>Name of the attribute to be converted.</description>
      </localName>
     <namespace label="Namespace" name="attribute_namespace" allowsAny="true">
       <description>Namespace of the attribute to be converted.</description>
     </namespace>
     </attributeParameter>
    </section>
    <section label="New element">
        <elementParameter>
           <localName label="Name" name="new_element_localName">
               <description>The name of the new element.</description>
           </localName>
           <namespace label="Namespace" name="new_element_namespace">
               <description>The namespace of the new element.</description>
           </namespace>
        </elementParameter>
    </section>
  </parameters>
</refactoringOperationDescriptor>
```

Note:

If you are using an XSLT file, the line with the `<script>` element would look like this:

```
<script type="XSLT" href="convert-attribute-to-element.xsl"/>
```

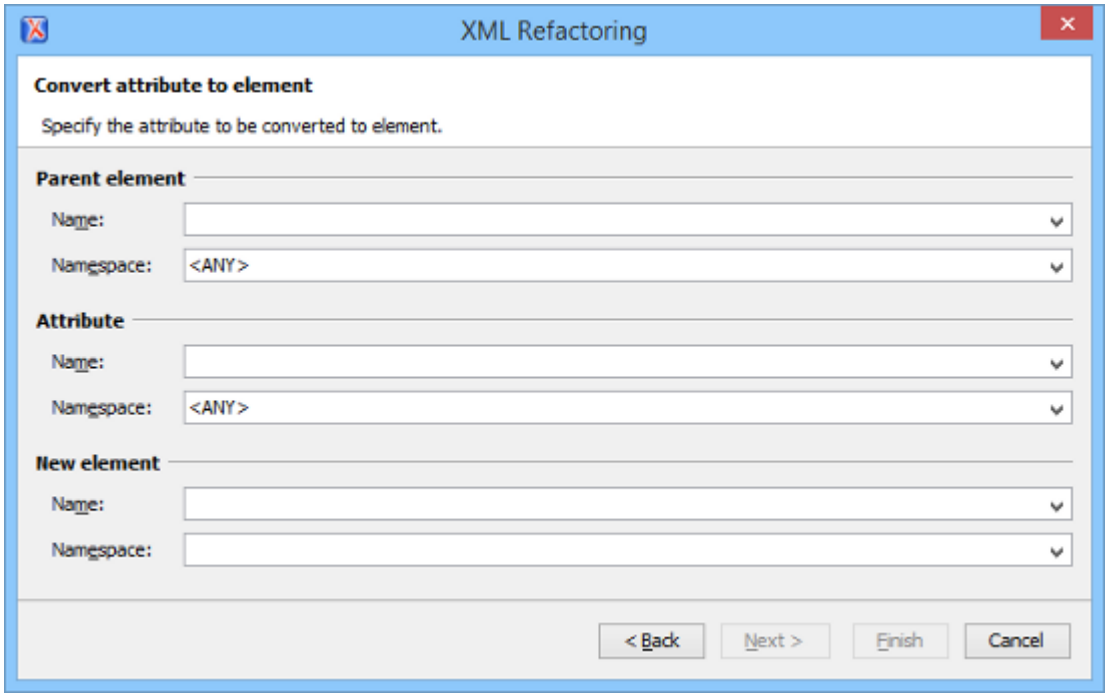
The code exemplified above and other refactoring examples can be found on the DITA Refactoring GitHub sample project.

Results

After you have created these files, copy them into a folder scanned by Oxygen XML Editor when it loads the custom operation *(on page 888)*. When the XML Refactoring tool is started again, you will see the created operation.

Since various parameters can be specified, this custom operation can also be used for other similar tasks. The following image shows the parameters that can be specified in the example of the custom operation to convert an attribute to an element:

Figure 644. Example: XML Refactoring Wizard for a Custom Operation



Using Saxon Extension Functions to Allow Custom Refactoring Operations to Read and Modify Content Outside the Root Node

One advantage to using an XSLT stylesheet is that there is limitation when using an XQuery Update script *(on page 876)* in that refactoring operations can only be performed on *comments* or *processing instructions* that are inside the root element. Thus, using the XQuery method, *comments* or *processing instructions* that are in any node before or after the root element cannot be modified by an XML Refactoring operation.

The XSLT stylesheet method offers a work-around to this limitation through the use of some Saxon extension functions.

To illustrate the use of these functions, consider the following sample XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- comment before root -->
<?pi before root ?>
<root>
    <child></child>
</root>
<!-- comment after root -->
<?pi after root ?>
```

The following Saxon extension functions can be used to read and modify content outside the root node:

Note:
They belong to the `http://www.oxygenxml.com/ns/xmlRefactoring/functions` namespace.

- **get-content-after-root()** - Returns the content after root as `xs:string`.

  For the XML above, the call of this function will return the following string value:

  ```
  <!-- comment after root -->
  <?pi after root ?>
  ```

- **set-content-after-root(xs:string)** - Updates the content that will be serialized in the refactored document after the root node.

  The function call `set-content-after-root('<!-- Inserted comment -->')` will result in replacing the nodes after the root element with the comment passed as string argument. The XML document will be modified as follows:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  <!-- comment before root -->
  <?pi before root ?>
  <root>
      <child></child>
  </root><!-- Inserted comment -->
  ```

- **get-content-before-root()** - Returns the content before root as `xs:string`.

  For the XML above, the call of this function will return the following string value:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  <!-- comment before root -->
  <?pi before root ?>
  ```

- **set-content-before-root(xs:string)** - Updates the content that will be serialized in the refactored document after the root node.

  The function call `set-content-before-root('<!-- Inserted comment -->')` will result in replacing the nodes before the root element with the comment passed as string argument. The XML document will be modified as follows:

  ```
  <!-- Inserted comment --><root>
      <child></child>
  </root>
  <!-- comment after root -->
  <?pi after root ?>
  ```

XSLT Example:

To process content after the root node, the XSLT would look like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema" exclude-result-prefixes="xs"
```

```
    xmlns:xrf="http://www.oxygenxml.com/ns/xmlRefactoring/functions" version="3.0">
    <xsl:template match="/">
        <!-- The comment content that will be inserted after the root element -->
        <xsl:variable name="commentAsText"><!-- COMMENT ADDED FROM XR OPERATION-->
        </xsl:variable>
        <!-- Retrieve the content after the root element as is -->
        <xsl:variable name="after-root-content" as="xs:string"
                      select="xrf:get-content-after-root()"/>

        <xsl:variable name="processedContent"
                      select="concat($after-root-content, $commentAsText)"/>

        <!-- Update the content after the root element -->
        <xsl:value-of select="xrf:set-content-after-root($processedContent)"/>

        <xsl:apply-templates/>
    </xsl:template>

    <xsl:template match="node() | @*">
        <xsl:copy>
            <xsl:apply-templates select="node() | @*"/>
        </xsl:copy>
    </xsl:template>
</xsl:stylesheet>
```

Note:
The above XSLT retrieves the nodes after the root element as string, appends a new comment, and then sets back the updated content into the XML document.

Storing and Sharing Refactoring Operations

Oxygen XML Editor scans the following locations when looking for XML Refactoring operations to provide flexibility:

- A folder named `refactoring`, created inside the folder of the *framework* you are customizing. In the **Classpath** tab of the **Document type** configuration dialog box *(on page 152)*, you need to add a reference to the `refactoring` folder specific for the framework.
- A folder that you specify in the **Load additional refactoring operations from** text box *(on page 277)* in the **XML Refactoring** preferences page *(on page 277)*.

Note:

If you share a project with your team, you can also share the custom operation by doing the following:

1. Save the custom operation in a folder that is part of your project.
2. Switch the **XML Refactoring** option page to project level *(on page 3423)*:
    a. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **XML > XML Refactoring** *(on page 277)*.
    b. Select **Project Options** *(on page 3423)* at the bottom of the dialog box.
3. In the **Load additional refactoring operations from** text box *(on page 277)*, use the *${pd}* editor variable *(on page 340)* so that the folder path is declared relative to the project.

- A folder specified by the XML Refactoring Operations Plugin Extension *(on page 2552)*.
- The `refactoring` folder from the Oxygen XML Editor installation directory (*`[OXYGEN_INSTALL_DIR]/refactoring/`*).

Sharing Custom Refactoring Operations

The purpose of Oxygen XML Editor scanning multiple locations for the XML Refactoring operations is to provide more flexibility for developers who want to share the refactoring operations with the other team members. Depending on your particular use case, you can attach the custom refactoring operations to other resources, such as *framework (on page 3420)* or projects.

After storing custom operations, you can share them with other users by sharing the resources.

Localizing XML Refactoring Operations

Oxygen XML Editor includes localization support for the XML refactoring operations.

The translation keys for the built-in refactoring operations are located in *`[OXYGEN_INSTALL_DIR]/refactoring/i18n/translation.xml`*.

The localization support is also available for custom refactoring operations. The following information can be translated:

- The operation `name`, `description`, and `category`.
- The `<description>` of the `<parameters>` element.
- The `label`, `description`, and `possibleValues` for each `parameter`.

Translated refactoring information uses the following form:

```
${i18n(translation_key)}
```

Oxygen XML Editor scans the following locations to find the `translation.xml` files that are used to load the translation keys:

- A `refactoring/i18n` folder, created inside a directory that is associated to a customized *framework*.
- A `i18n` folder, created inside a directory that is associated to a customized *framework*.
- An `i18n` folder inside any specified folder. In this case, you need to open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **XML > XML Refactoring**, and specify the folder in the **Load additional refactoring operations from** text box.
- An `i18n` folder located in directories specified through the XML Refactoring Operations Plugin Extension *(on page 2552)*.
- The `refactoring/i18n` folder from the Oxygen XML Editor installation directory (*`[OXYGEN_INSTALL_DIR]`*`/refactoring/i18n`).

Example: Refactoring Operation Descriptor File with *i18n* Support

```
<?xml version="1.0" encoding="UTF-8"?>

<refactoringOperationDescriptor
    xmlns="http://www.oxygenxml.com/ns/xmlRefactoring" id="remove_text_content"
           name="${i18n(Remove_text_content)}">
    <description>${i18n(Remove_text_content_description)}</description>
    <script type="XQUERY_UPDATE" href="remove_text_content.xq"/>
    <parameters>
        <description>${i18n(parameters_description)}</description>
        <parameter label="${i18n(Element_name)}" name="element_localName"
                      type="NC_NAME">
            <description>${i18n(Element_name_descriptor)}</description>
            <possibleValues>
                <value default="true" name="value1">${i18n(value_1)}</value>
                <value name="value2">${i18n(value_2)}</value>
            </possibleValues>
        </parameter>
    </parameters>
</refactoringOperationDescriptor>
```

Generating Sample XML Files

Oxygen XML Editor offers support to generate sample XML files both from XML schema 1.0 and XML schema 1.1, depending on the XML schema version set in **XML Schema** preferences page *(on page 247)*.

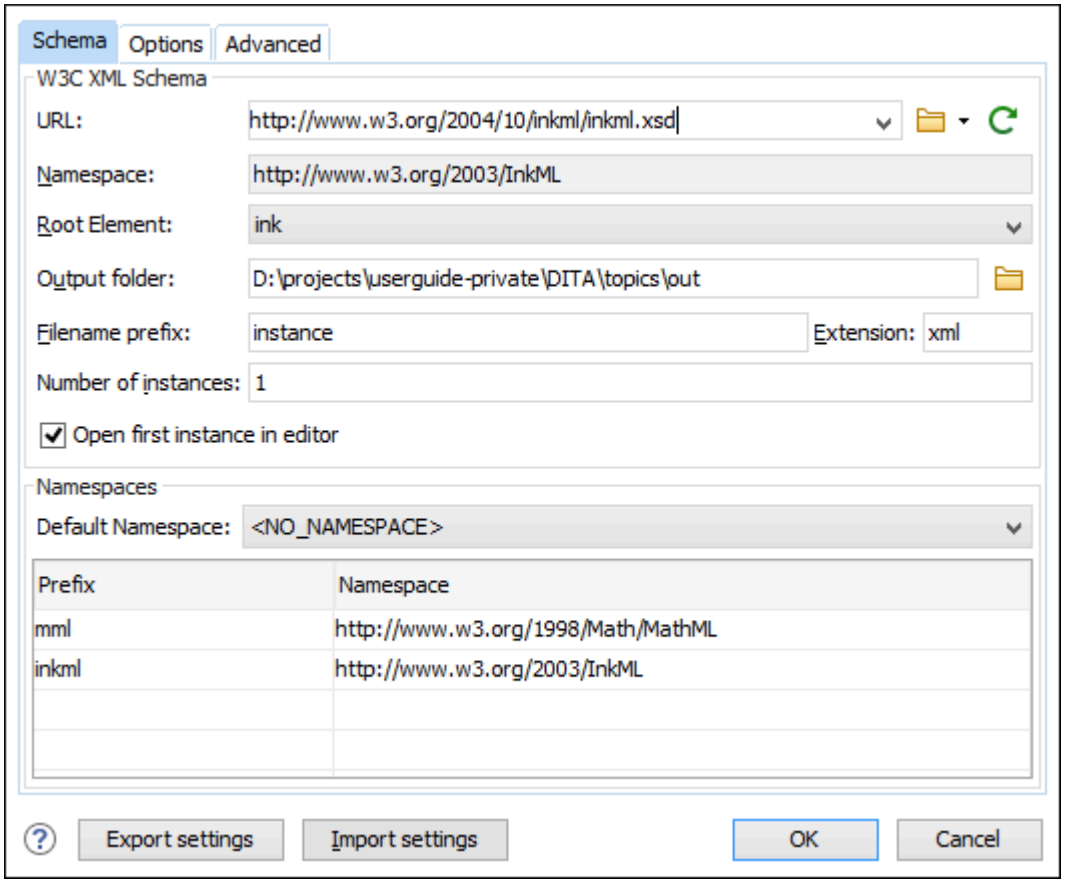
To generate sample XML files from an XML Schema, use the **Generate Sample XML Files** action from the **Tools** menu. This action is also available in the contextual menu of the schema Design mode *(on page 965)*. The action opens the **Generate Sample XML Files** dialog box that allows you to configure a variety of options for generating the files.

The **Generate Sample XML Files** dialog box contains three tabs with various configurable options. Default values for these options can be set in the **Sample XML Files Generator** preferences page *(on page 250)*. You can also run the tool from the command line using exported options.

Schema Tab

The first set of options for the **Generate Sample XML Files** tool are found in the **Schema** tab.

Figure 645. Generate Sample XML Files Dialog Box (Schema Tab)



This tab includes the following options:

URL

Specifies the URL of the Schema location. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the **Browse** drop-down list.

Namespace

Displays the namespace of the selected schema.

Root Element

After the schema is selected, this drop-down menu is populated with all root candidates gathered from the schema. Choose the root of the output XML documents.

Output folder

Path to the folder where the generated XML instances will be saved.

Filename prefix and Extension

You can specify the prefix and extension for the file name that will be generated. Generated file names have the following format: `prefixN.extension`, where `N` represents an incremental number from 0 up to the specified **Number of instances**.

Number of instances

The number of XML files to be generated.

Open first instance in editor

When selected, the first generated XML file is opened in the editor.

Namespaces section

You can specify the **Default Namespace**, as well as the prefixes for the namespaces.

Export settings

Use this button to save the current settings for future use.

Import settings

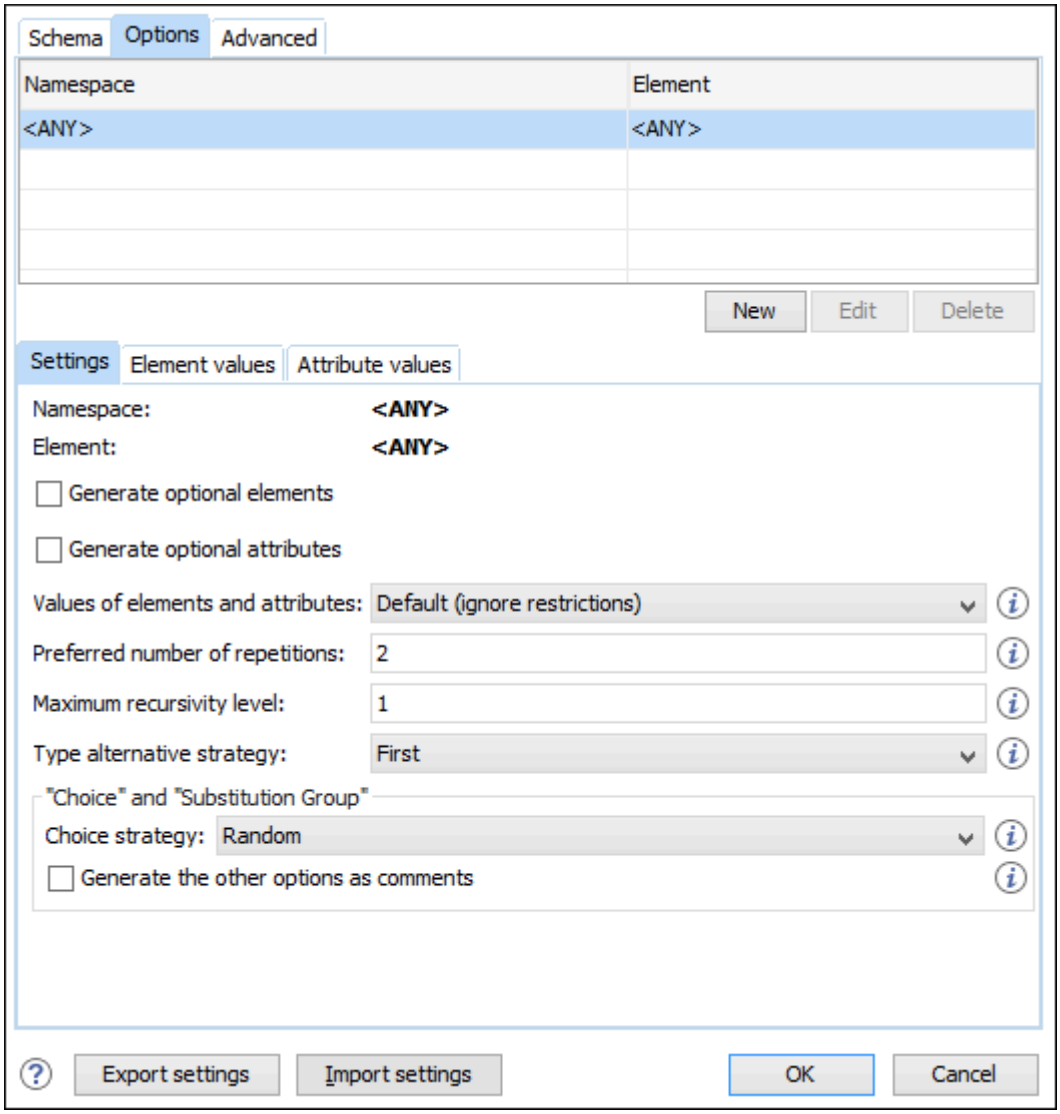
Use this button to load previously exported settings.

You can click **OK** at any point to generate the sample XML files.

Options Tab

The **Options** tab allows you to set specific options for namespaces and elements.

Figure 646. Generate Sample XML Files Dialog Box (Options Tab)



This tab includes the following options:

Namespace / Element table

Allows you to set a namespace for each element name that appears in an XML document instance. The following prefix-to-namespace associations are available:

- All elements from all namespaces (`<ANY>` - `<ANY>`). This is the default setting.
- All elements from a specific namespace.
- A specific element from a specific namespace.

Settings subtab

Namespace

Displays the namespace specified in the table at the top of the dialog box.

Element

Displays the element specified in the table at the top of the dialog box.

Generate optional elements

When selected, all elements are generated, including the optional ones (having the `minOccurs` attribute set to 0 in the schema).

Generate optional attributes

When selected, all attributes are generated, including the optional ones (having the `use` attribute set to `optional` in the schema).

Values of elements and attributes

Controls the content of generated attribute and element values. The following choices are available:

- **None** - No content is inserted.
- **Default** - Inserts a default value depending on the data type descriptor of the particular element or attribute. The default value can be either the data type name or an incremental name of the attribute or element (according to the global option from the **Sample XML Files Generator** preferences page). Note that type restrictions are ignored when this option is selected. For example, if an element is of a type that restricts an **xs:string** with the **xs:maxLength** facet to allow strings with a maximum length of 3, the XML instance generator tool may generate string element values longer than 3 characters.
- **Random** - Inserts a random value depending on the data type descriptor of the particular element or attribute.

Important:
If all of the following are true, the **Generate Sample XML Files** tool outputs invalid values:
  - At least one of the restrictions is a `regexp`.
  - The value generated after applying the regexp does not match the restrictions imposed by one of the facets.

Preferred number of repetitions

Allows you to set the preferred number of repeating elements related to `minOccurs` and `maxOccurs` facets defined in the XML Schema.

- If the value set here is between `minOccurs` and `maxOccurs`, then that value is used.
- If the value set here is less than `minOccurs`, then the `minOccurs` value is used.
- If the value set here is greater than `maxOccurs`, then `maxOccurs` is used.

Maximum recursion level

If a recursion is found, this option controls the maximum allowed depth of the same element.

Type alternative strategy

Used for the `<xs:alternative>` element from XML Schema 1.1. The possible strategies are:

- **First** - The first valid alternative type is always used.
- **Random** - A random alternative type is used.

Choice strategy

Used for `<xs:choice>` or `<substitutionGroup>` elements. The possible strategies are:

- **First** - The first branch of `<xs:choice>` or the head element of `<substitutionGroup>` is always used.
- **Random** - A random branch of `<xs:choice>` or a substitute element or the head element of a `<substitutionGroup>` is used.

Generate the other options as comments

If selected, generates the other possible choices or substitutions (for `<xs:choice>` and `<substitutionGroup>`). These alternatives are generated inside comments groups so you can uncomment and use them later. Use this option with care (for example, on a restricted namespace and element) as it may generate large result files.

Element values subtab

Allows you to add values that are used to generate the content of elements. If there are multiple values, then the values are used in a random order.

Attribute values subtab

Allows you to add values that are used to generate the content of attributes. If there are multiple values, then the values are used in a random order.

Export settings

Use this button to save the current settings for future use.

Import settings

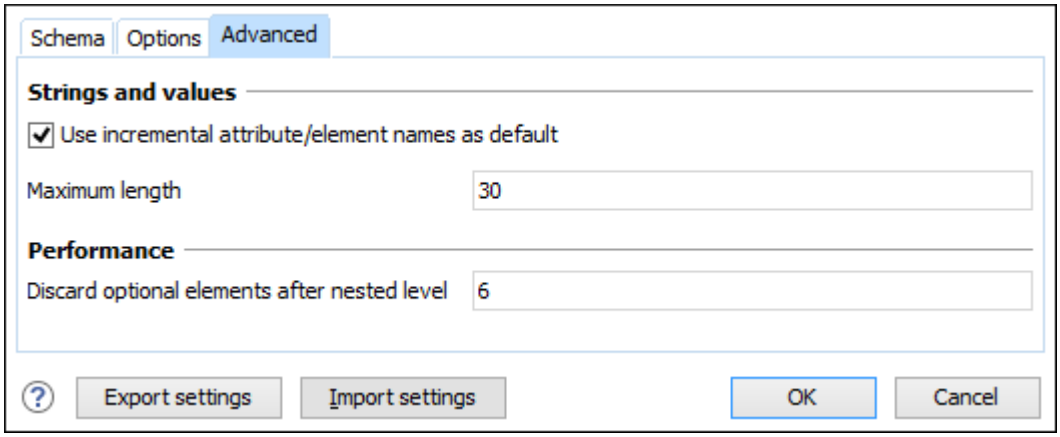
Use this button to load previously exported settings.

You can click **OK** at any point to generate the sample XML files.

Advanced Tab

The **Advanced** tab allows you to set some options regarding output values and performance.

Figure 647. Generate Sample XML Files Dialog Box (Advanced Tab)



This tab includes the following options:

Use incremental attribute / element names as default

If selected, the value of an element or attribute starts with the name of that element or attribute. For example, for an `<a>` element the generated values are: `a1`, `a2`, `a3`, and so on. If not selected, the value is the name of the type of that element / attribute (for example: `string`, `decimal`, etc.)

Maximum length

The maximum length of string values generated for elements and attributes.

Discard optional elements after nested level

The optional elements that exceed the specified nested level are discarded. This option is useful for limiting deeply nested element definitions that can quickly result in very large XML documents.

Export settings

Use this button to save the current settings for future use.

Import settings

Use this button to load previously exported settings.

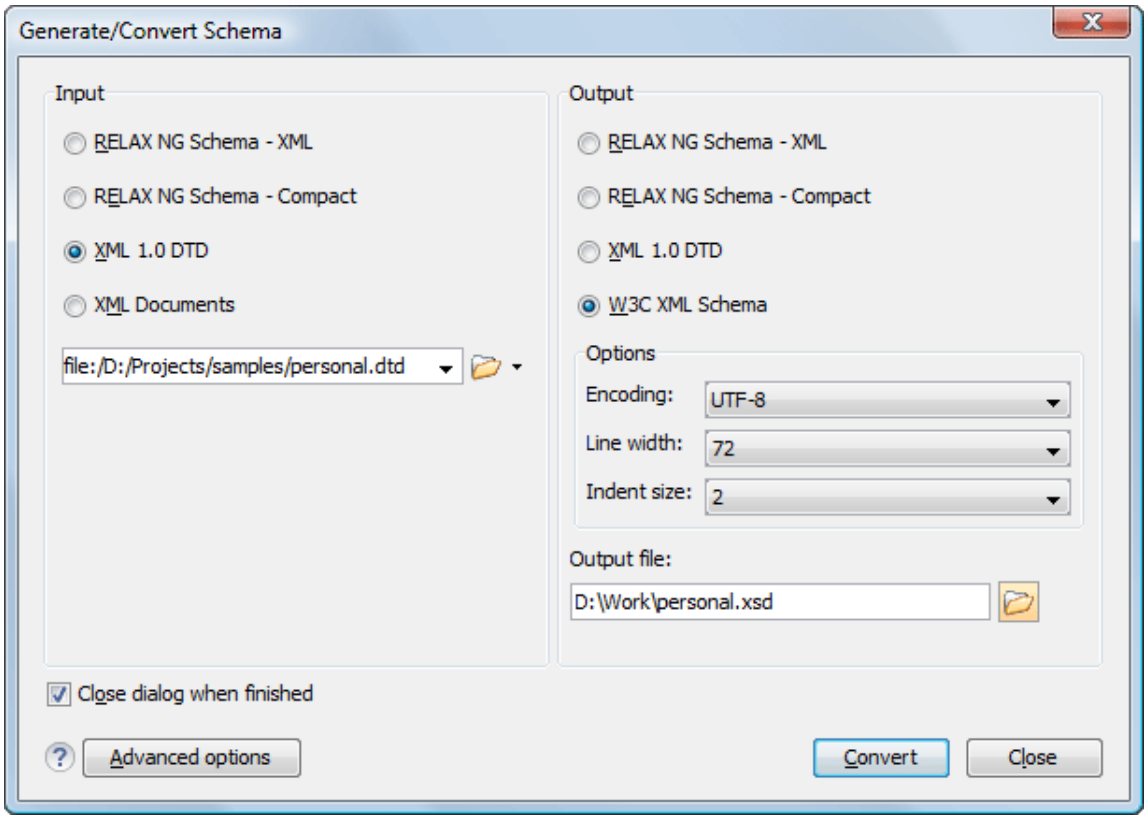
Tip:
This function can be executed from an automated command-line script, for more details, see Scripting Oxygen *(on page 3383)*.

Converting Schema to Another Schema Language

The **Generate/Convert Schema** tool allows you to convert a DTD or Relax NG (full or compact syntax) schema or a set of XML files to an equivalent XML Schema, DTD or Relax NG (full or compact syntax) schema. Where perfect equivalence is not possible due to limitations of the target language, Oxygen XML Editor generates an approximation of the source schema. Oxygen XML Editor uses the *Trang multiple format converter* to perform the actual schema conversions.

To use this tool, select the **Generate/Convert Schema (Alt + Shift + C (Command + Option + C on macOS))** action from the **Tools** menu or from the **Open with** submenu when invoking the contextual menu in the **Project** view *(on page 413)*. This action opens the **Generate/Convert Schema** dialog box that allows you to configure various options for conversion.

Figure 648. Generate/Convert Schema Dialog Box



The **Generate/Convert Schema** dialog box includes the following options:

Input section

Allows you to select the language of the source schema. If the conversion is based on a set of XML files, rather than just a single XML file, select the **XML Documents** option and use the file selector to add the XML files involved in the conversion.

Output section

Allows you to select the language of the target schema.

Options

You can choose the **Encoding**, the maximum **Line width**, and the **Indent size** (in number of spaces) for one level of indentation.

Output file

Specifies the path for the output file that will be generated.

Close dialog when finished

If you deselect this option, the dialog box will remain open after the conversion so that you can easily continue to convert more files.

Advanced options

If you select **XML 1.0 DTD** for the input, you can click this button to access more advance options to further fine-tune the conversion. The following advanced options are available:

XML 1.0 DTD Input section

These options apply to the source DTD:

- **xmlns** - Specifies the default namespace, that is the namespace used for unqualified element names.
- **attlist-define** - Specifies how to construct the name of the definition representing an attribute list declaration from the name of the element. The specified value must contain exactly one percent character. This percent character is replaced by the name of element (after colon replacement) and the result is used as the name of the definition.
- **colon-replacement** - Replaces colons in element names with the specified chars when constructing the names of definitions used to represent the element declarations and attribute list declarations in the DTD.
- **any-name** - Specifies the name of the definition generated for the content of elements declared in the DTD as having a content model of ANY.
- **element-define** - Specifies how to construct the name of the definition representing an element declaration from the name of the element. The specified value must contain exactly one percent character. This percent character is replaced by the name of element (after colon replacement) and the result is used as the name of the definition.
- **annotation-prefix** - Default values are represented using a `@prefix:defaultValue` annotation attribute where prefix is the specified value and is bound to `http://relaxng.org/ns/compatibility/annotations/1.0` as defined by the RELAX NG DTD Compatibility Committee Specification. By default, the conversion engine will use a for prefix unless that conflicts with a prefix used in the DTD.
- **inline-attlist** - Instructs the application not to generate definitions for attribute list declarations, but instead move attributes declared in attribute list declarations into the definitions generated for element declarations. This is the default behavior when the output language is XSD.
- **strict-any** - Preserves the exact semantics of *ANY* content models by using an explicit choice of references to all declared elements. By default, the conversion engine uses a wildcard that allows any element
- **generate-start** - Specifies whether or not the conversion engine should generate a start element. DTD's do not indicate what elements are allowed

as document elements. The conversion engine assumes that all elements that are defined but never referenced are allowed as document elements.
- **xmlns mappings** table - Each row specifies the prefix used for a namespace in the input schema.

W3C XML Schema Output section

This section is available if you select **W3C XML Schema** for the output.

- **disable-abstract-elements** - Disables the use of abstract elements and substitution groups in the generated XML Schema. This can also be controlled using an annotation attribute.
- **any-process-contents** - One of the values: strict, lax, skip. Specifies the value for the `@processContents` attribute of any elements. The default is skip (corresponding to RELAX NG semantics) unless the input format is DTD, in which case the default is strict (corresponding to DTD semantics).
- **any-attribute-process-contents** - Specifies the value for the `@processContents` attribute of `<anyAttribute>` elements. The default is skip (corresponding to RELAX NG semantics).

Converting Database to XML Schema

Oxygen XML Editor includes a tool that allows you to create an XML Schema from the structure of a database.

To convert a database structure to an XML Schema, use the following procedure:

1. Select the **Convert DB Structure to XML Schema** action from the **Tools** menu.

   Result: The **Convert DB Structure to XML Schema** dialog box is opened and your current database connections are displayed in the **Connections** section.
2. If the database source is not listed, click the **Configure Database Sources** button to open the **Data Sources** preferences page *(on page 285)* where you can configure data sources and connections.
3. In the **Format for generated schema** section, select one of the following formats:
   - **Flat schema** - A flat structure that resembles a tree-like view of the database without references to elements.
   - **Hierarchical schema** - Display the table dependencies visually, in a type of tree view where dependent tables are shown as indented child elements in the content model. Select this option if you want to configure the database columns of the tables to be converted.
4. Click **Connect**.

   Result: The database structure is listed in the **Select database tables** section according to the format you chose.
5. Select the database tables that you want to be included in the XML Schema.
6. If you selected **Hierarchical schema** for the format, you can configure the database columns.

a. Select the database column you want to configure.
b. In the **Criterion** section you can choose to convert the selected database column as an **Element**, **Attribute**, or to be **Skipped** in the resulting XML Schema.
c. You can also change the name of the selected database column by changing it in the **Name** text field.

7. Click **Generate XML Schema**.

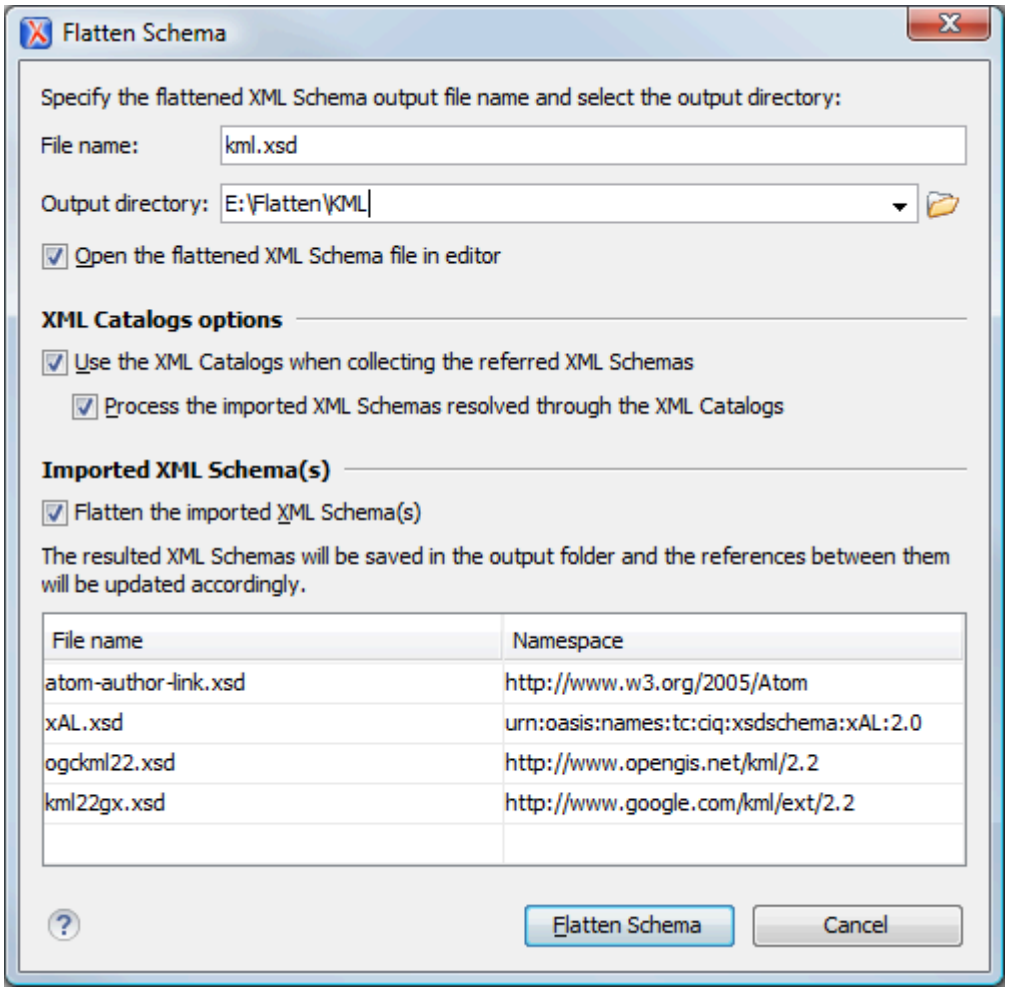
Result: The database structure is converted to an XML Schema and it is opened for viewing and editing.

Flatten an XML Schema

You can organize an XML schema linked by `<xs:include>` and `<xs:import>` statements on several levels. In some cases, working on such a schema as if it were a single file is more convenient than working on multiple files separately. The **Flatten Schema** operation allows you to flatten an entire hierarchy of XML schemas. Starting with the main XML schema, Oxygen XML Editor calculates its hierarchy by processing the `<xs:include>` and `<xs:import>` statements.

The **Flatten Schema** action is available from the **Tools** menu or the contextual menu in **Text** mode. This action opens the **Flatten Schema** dialog box that allows you to configure the operation.

Figure 649. Flatten Schema Dialog Box



For the main schema file and for each imported schema, a new flattened schema is generated in the specified output folder. These schemas have the same name as the original ones.

> **Note:**
> If necessary, the operation renames the resulted schemas to avoid duplicated file names.

A flattened XML schema is obtained by recursively adding the components of the included schemas into the main one. This means Oxygen XML Editor replaces the `<xs:include>`, `<xs:redefine>`, and `<xs:override>` elements with the ones coming from the included files.

Options in the Flatten Schema Dialog Box

The following options are available in the **Flatten Schema** dialog box:

File name

The name of the output file.

Output directory

The path of the output directory where the flattened schema file will be saved.

Open the flattened XML Schema file in editor

Opens the main flattened schema in the editing area after the operation completes.

Use the XML Catalogs when collecting the referenced XML Schemas

Enables the imported and included schemas to be resolved through the available *XML Catalogs (on page 3425)*.

> **Note:**
> Changing this option triggers the recalculation of the dependencies graph for the main schema.

Process the imported XML Schemas resolved through the XML Catalogs

Specifies whether or not the imported schemas that were resolved through an *XML Catalog (on page 3425)* are also processed.

Flatten the imported XML Schema(s)

Specifies whether or not the imported schemas are flattened.

> **Note:**
> For the schemas skipped by the flatten operation, no files are created in the output folder and the corresponding import statements remain unchanged.

Tip:
This function can be executed from an automated command-line script, for more details, see Scripting Oxygen *(on page 3383)*.

Generating Java Classes from XML Schema

Oxygen XML Editor includes a tool for generating Java classes from an XML Schema (XSD) file. The **Generate Java classes from XML Schema (XSD)** action for invoking the tool can be found in the **Tools** menu. It requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor will present a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the action will invoke the Java class generator tool.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.
3. Select the **Java Classes Generator** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **Generate Java classes from XML Schema (XSD)** dialog box is now available and can be selected from the **Tools** menu.

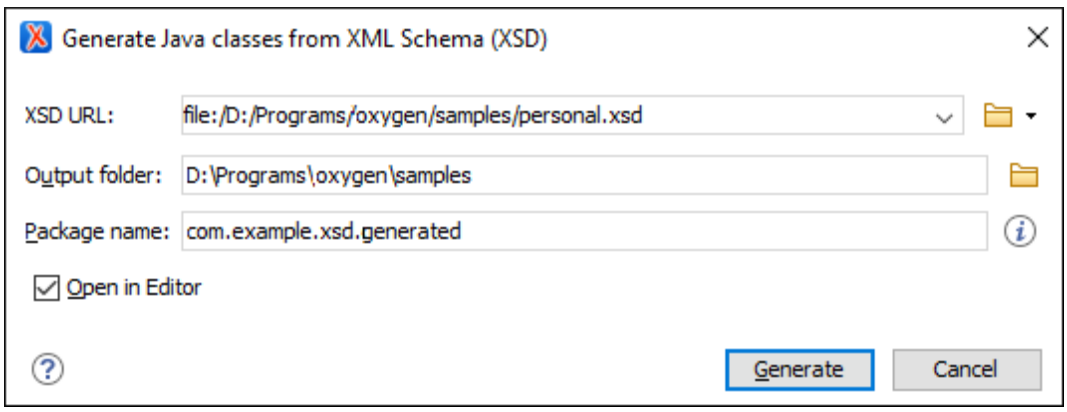
Generating Java Classes

To generate Java classes, follow these steps:

1. Select the **Generate Java classes from XML Schema (XSD)** action from the **Tools** menu.

   Step Result: The **Generate Java classes from XML Schema (XSD)** dialog box is displayed:

   Figure 650. Generate Java Classes from XML Schema (XSD) Dialog Box

2. Choose or enter the **XSD URL** of the XML Schema document.
3. Choose the path for the **Output folder** where the generated files will be stored.
4. [Optional] You can choose the **Package name** for the Java package that will contain the generated source files. If not specified, the name will be generated based on the value of the `@targetNamespace` attribute.
5. [Optional] You can select the **Open in Editor** option to open the `ObjectFactory.java` file in the editor. This java class contains factory methods for all other classes in the package.
6. Click the **Generate** button.

Result: The Java class files will be generated inside the new package, located in the specified output folder.

Compiling an XSL Stylesheet for Saxon

As of Saxon 12.3, it is possible to export a compiled form of a stylesheet as a JSON or XML file (called a *stylesheet export file* or SEF). Oxygen XML Editor includes a simple tool called **Compile XSL Stylesheet for Saxon** (found in the **Tools** menu) that does this for you.

Use-Cases for a Stylesheet Export File (SEF)

- **Use Saxon-JS to run transformations in a browser** - A *stylesheet export file* (SEF) is needed if you want to use the Saxon-JS product to run transformations in a browser, as in the following example:

```
<script type="text/javascript" src="SaxonJS/SaxonJS.min.js"></script>
<script>
    window.onload = function() {
      SaxonJS.transform({
         stylesheetLocation: "books.sef",
         sourceLocation: "books.xml"
         });
```

```
    }
</script>
```

- **Use SEF to run transformations in Oxygen XML Editor** - You can also use a *stylesheet export file* (SEF) in Oxygen XML Editor to apply an XSLT transformation over an XML file. This requires **Saxon-EE** or **Saxon-PE** versions of the Saxon product and you must select one of those two versions for the **Target** when you configure the SEF file *(on page 2788)*. When configuring the XSLT transformation, you will specify the SEF file in the **XSL URL** field *(on page 1505)*.

Compiling an SEF File

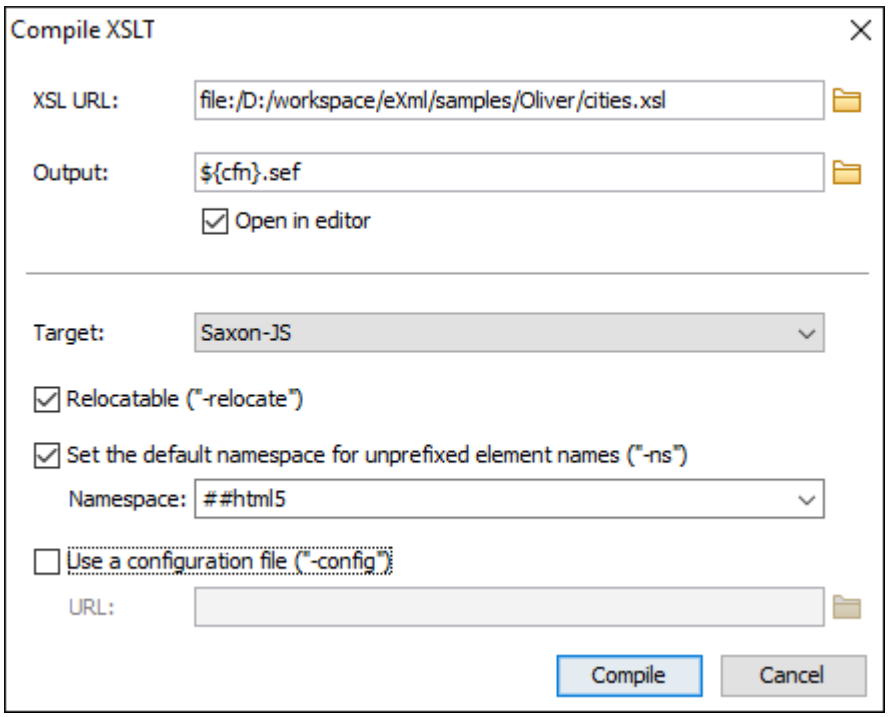
The **Compile XSL Stylesheet for Saxon** tool can be found in the **Tools** menu and it compiles a specified stylesheet as a JSON or an XML file (*stylesheet export file*).

If you choose **Saxon-JS** as the **Target** (the type of Saxon product that the export file will be used with), then the compiled stylesheet will be a JSON file with a file extension of `.sef` by default.

If you choose **Saxon-EE**, **Saxon-PE**, or **Saxon-HE** for the **Target**, then the compiled stylesheet will be an XML file with a file extension of `.xsef` by default.

Selecting this tool opens the **Compile XSL Stylesheet for Saxon** dialog box that allows you to configure some options for conversion.

Figure 651. Compile XSLT Stylesheet for Saxon Dialog Box



This dialog box includes the following options:

XSL URL

Allows you to select URL of the source XSL stylesheet. You can specify the URL by using the text field, the history drop-down, or the browsing actions in the **Browse** drop-down list.

Output file

You can specify the path where the output file will be saved by entering it in the text field, using the  **Insert Editor Variables** button, or using the browsing actions in the  **Browse** drop-down list.

Open in Editor

Select this option to open the resulting *stylesheet export file* in the main Oxygen XML Editor editing pane.

Target

Allows you to select the type of Saxon product that the export file will be used with. You can choose **Saxon-JS**, **Saxon-EE**, **Saxon-PE**, or **Saxon-HE**.

Relocatable

Can be used to control the Saxon `-relocate` parameter. You can select this option to produce a *relocatable* export package (SEF) that can be deployed to a different location, with a different base URI.

Set the default namespace for unprefixed element names ("-ns")

Can be used to control the `-ns:(uri|##any|##html5)` Saxon parameter that defines the handling of unprefixed element names that appear as name tests in path expressions and match patterns in the stylesheet:

- The **##any** value declares that unprefixed names are treated as a test on the local name of the element only. They will match regardless of namespace.
- The **##html5** value declares that an unprefixed element name will match either a name in the XHTML namespace or a name in no namespace. This option is primarily intended for use when generating stylesheets to run under Saxon-JS in the browser since the resulting behavior is close to that defined by the special rules in the HTML5 specification for XSLT and XPath running against an HTML5 DOM.
- You can also specify a valid URI by editing the value in the combo box. Specifying a URI sets the default namespace for elements and types (effectively a default value for `xpath-default-namespace`). Note that an explicit value for this attribute takes precedence.

Use a configuration file ("-config")

Select this option if you want to use a Saxon 12.3 configuration file that will be executed for the XSLT transformation and validation processes. You can specify the path to the configuration file by entering it in the **URL** field, or by using the  **Insert Editor Variables** button, or using the browsing actions in the  **Browse** drop-down list.

Compile

Use this button to generate the *stylesheet export file* according the options selected in this dialog box.

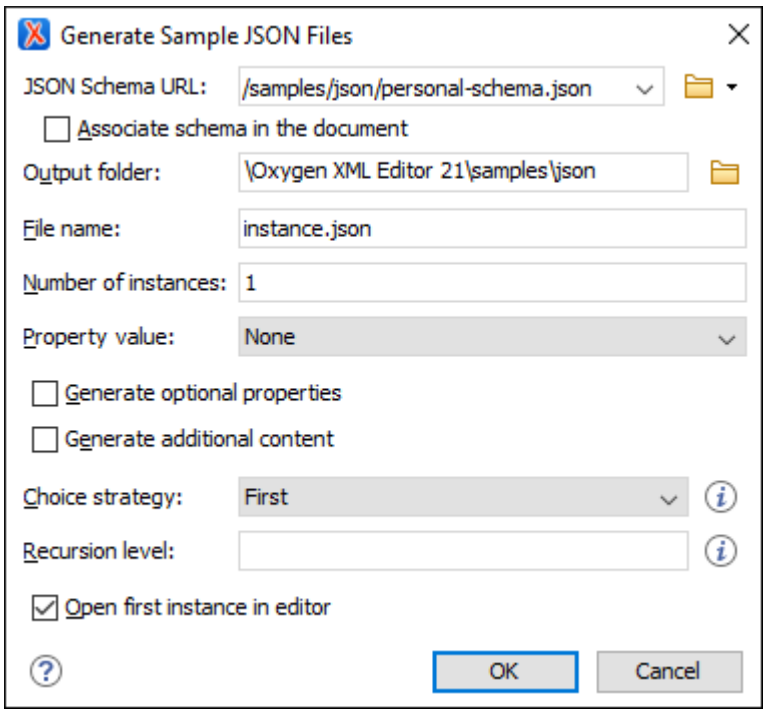
JSON Tools

Oxygen XML Editor includes some useful tools for converting between JSON, XML and YAML, converting XSD to JSON Schema, generating JSON instances or a JSON Schema, and OpenAPI (JSON and YAML) testing.

Generating Sample JSON Files from a JSON Schema

Oxygen XML Editor includes a tool for generating sample JSON files. To generate sample JSON files from a JSON Schema, select **Generate Sample JSON Files** from the **Tools > JSON Tools** menu. The action opens a dialog box where you can configure a variety of options for generating the files.

Figure 652. Generate Sample JSON Files Dialog Box



The **Generate Sample JSON Files** dialog box includes the following fields and options:

Schema URL

The URL of the Schema location. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the **Browse** drop-down list. The tool supports schemas with versions *Draft 04*, *06*, *07*, *2019-09*, and *2020-12*.

Associate schema in the document

If enabled, the specified schema will be associated with the generated files.

Output folder

Path to the folder where the generated JSON instances will be saved.

File name

The name of the instance(s) that will be generated. By default, `instance.json` is used.

Number of instances

The desired number of JSON instances to be generated. When more than one instance is generated, the index of the instance will be added to its file name.

Property value

You can specify the way the values of the properties are generated. The following options are available:

- *None* - Assigns empty values for properties (a template file will be generated). This is the default value.
- *Default* - Assigns the name of the property as the value (for strings) or assigns the specified minimum value (for numbers).
- *Random* - Assigns random values according to schema restrictions.

Generate optional properties

If selected, the JSON instance will be generated with optional properties that are defined in the JSON schema. Otherwise, only the required properties will be generated.

Generate additional content

If selected, the JSON instance will be generated with additional properties that are defined in the JSON schema as `additionalProperties` and additional items that are defined as `additionalItems` (in the case of an Array).

Choice strategy

You can specify the way an instance will be generated from a schema that contains a `CombinedSchema` (with either *oneOf* or *anyOf*). The following options are available:

- *First* - The first defined schema in *oneOf* or *anyOf* will be used.
- *Random* - A random schema defined in *oneOf* or *anyOf* will be used.

Recursion level

This option controls the maximum allowed depth (must be a number), in case the selected schema contains recursive calls of `$ref` schemas referencing one another. By default, it is set to 1, meaning that the generation for the recursive calls will stop after the first iteration.

Open first instance in editor

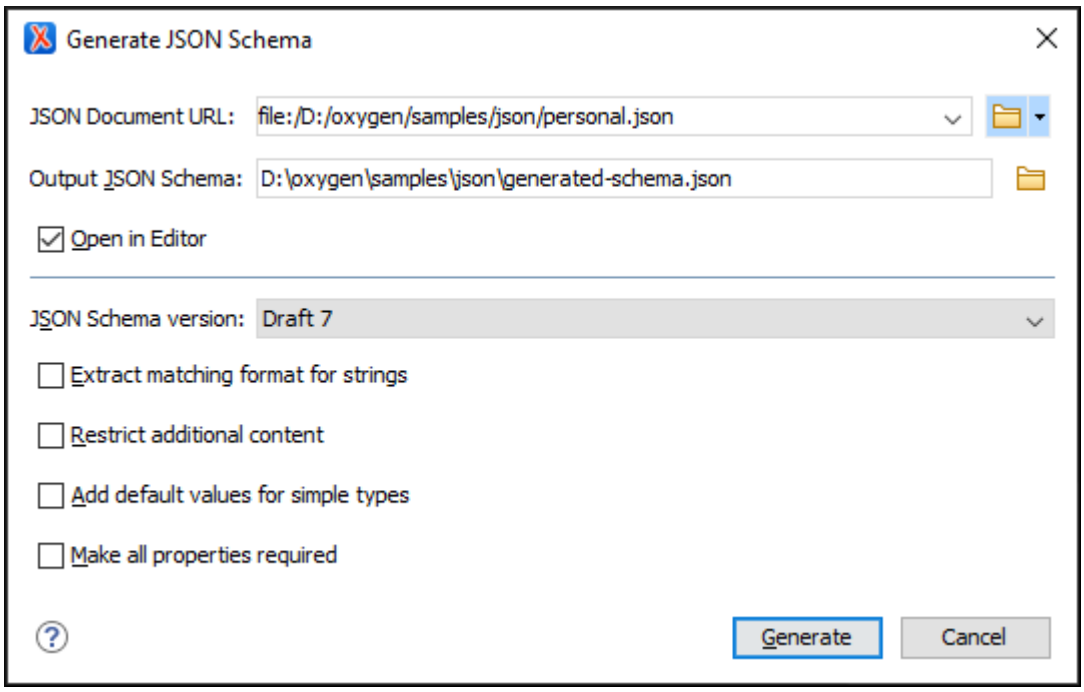
If selected, the first generated instance is opened in the editor.

You can click **OK** at any point to generate the sample JSON files.

Generating JSON Schema from a JSON File

Oxygen XML Editor includes a tool for generating a sample JSON Schema from a JSON file. To generate a sample JSON Schema, select **Generate JSON Schema** from the **Tools > JSON Tools** menu. The action opens a dialog box where you can configure some options for generating the JSON Schema.

Figure 653. Generate JSON Schema Dialog Box



The **Generate JSON Schema** dialog box includes the following fields and options:

JSON Document URL

The URL of the JSON file. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the **Browse** drop-down list.

Output JSON Schema

The path to the folder where the generated JSON Schema will be saved.

Open in Editor

If selected, the generated JSON Schema is opened in the editor.

JSON Schema version

The version of the resulting JSON schema. The possible choices are: **Draft 4**, **Draft 6**, **Draft 7**, **2019-09**, and **2020-12**.

Extract matching format for strings

If selected, the generator will attempt to find a format that matches the string values from the JSON Document.

Restrict additional content

If selected, *additionalProperties* (for objects) and *additionalItems* (for arrays) will be set to *false* in the resulting schema. By default, these keys are not in the schema, meaning that providing additional content (according to the schema) is allowed.

Add default values for simple types

If selected, the *default* values (*0* for number, *""* for string, *false* for boolean) and *examples* for strings will be added.

Make all properties required

If selected, the generator will mark all the properties as required in the resulting schema.

You can click **Generate** at any point to generate the JSON Schema.

JSON to YAML Converter

Converting JSON to YAML in Oxygen

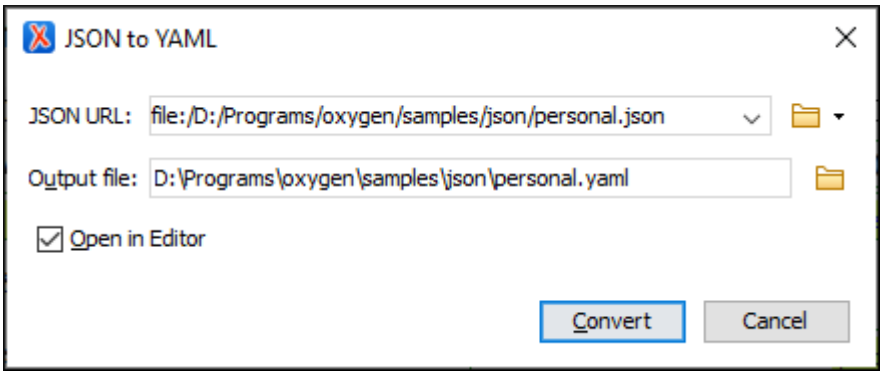
Oxygen XML Editor includes a useful and simple tool for converting JSON files to YAML. The **JSON to YAML** action for invoking the tool can be found in the **Tools > JSON Tools** menu.

To convert a JSON document to YAML, follow these steps:

1. Select the **JSON to YAML** action from the **Tools > JSON Tools** menu.

   The **JSON to YAML** dialog box is displayed:

   Figure 654. JSON to YAML Dialog Box

2. Choose or enter the **JSON URL** for the document you want to convert.
3. Choose the path of the **Output file** that will contain the resulting YAML document.
4. **[Optional]** Select the **Open in Editor** option to open the resulting YAML document in the main editing pane.
5. Click the **Convert** button.

Result: The original JSON document is now converted to a YAML document.

Related Information:

YAML to JSON Converter *(on page 1154)*

YAML to JSON Converter

Converting YAML to JSON in Oxygen

Oxygen XML Editor includes a useful and simple tool for converting YAML files to JSON. It even works on files that consist of multiple YAML documents, each separated by three dashes (---), in which case the conversion creates multiple JSON files with a number in the name.

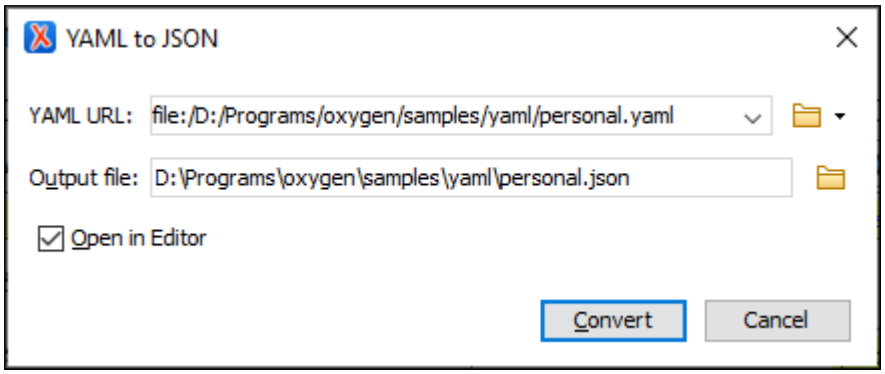
The **YAML to JSON** action for invoking the tool can be found in the **Tools > JSON Tools** menu.

To convert a YAML document to JSON, follow these steps:

1. Select the **YAML to JSON** action from the **Tools > JSON Tools** menu.

   The **YAML to JSON** dialog box is displayed:

   Figure 655. YAML to JSON Dialog Box

2. Choose or enter the **YAML URL** for the document you want to convert.
3. Choose the path of the **Output file** that will contain the resulting JSON document.
4. **[Optional]** Select the **Open in Editor** option to open the resulting JSON document in the main editing pane.
5. Click the **Convert** button.

Result: The original YAML document is now converted to a JSON document.

JSON to XML Converter

Online JSON to XML Converter

Attention:

For a simple ONLINE tool for converting a single JSON file to XML, or vice versa, go to: https://www.oxygenxml.com/xml_json_converter.html.

Converting JSON to XML in Oxygen

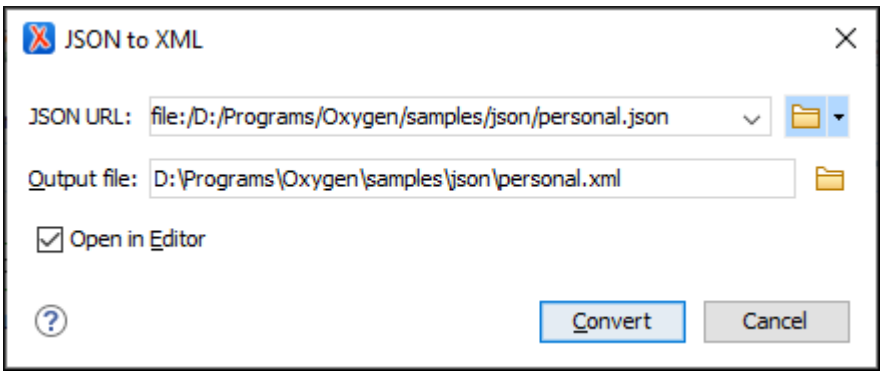
Oxygen XML Editor includes a useful and simple tool for converting JSON files to XML. The **JSON to XML** action for invoking the tool can be found in the **Tools > JSON Tools** menu.

To convert a JSON document to XML, follow these steps:

1. Select the **JSON to XML** action from the **Tools > JSON Tools** menu.

   The **JSON to XML** dialog box is displayed:

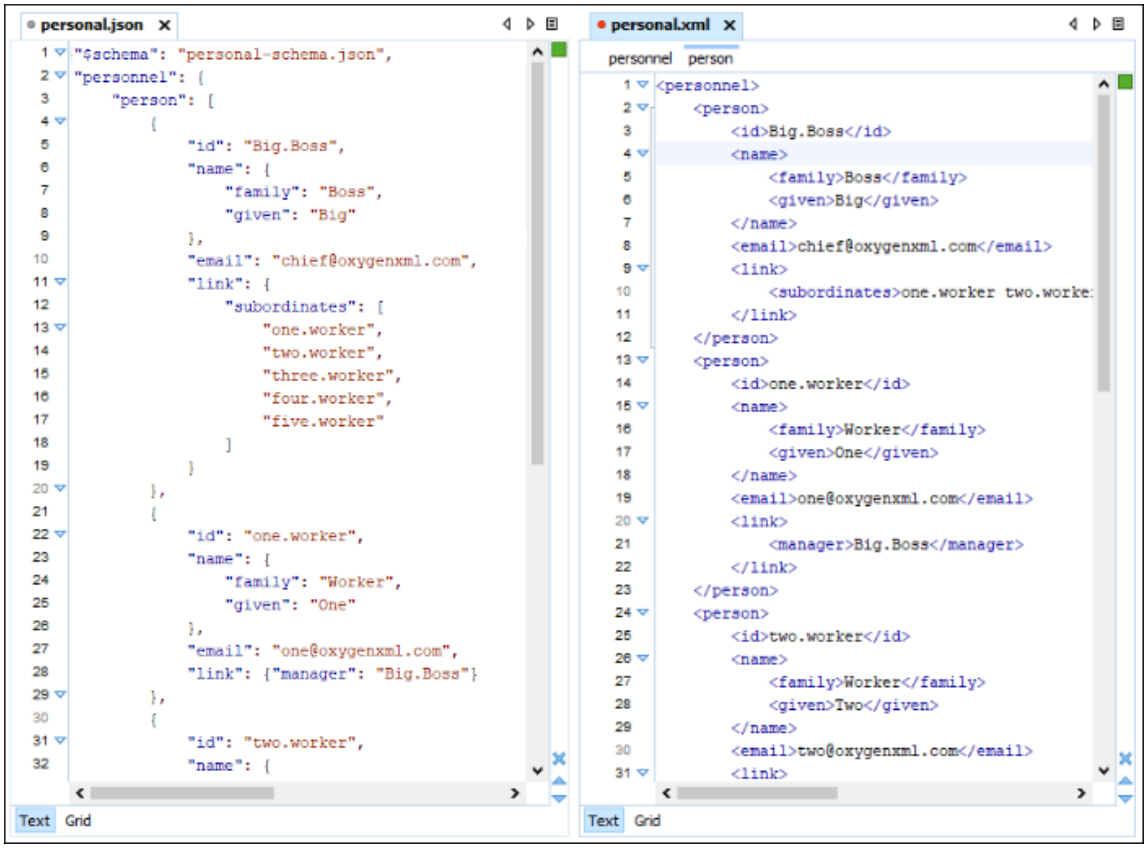
   Figure 656. JSON to XML Dialog Box

2. Choose or enter the **Input URL** of the JSON document.
3. Choose the path of the **Output file** that will contain the resulting XML document.
4. Select the **Open in Editor** option to open the resulting XML document in the main editing pane.
5. Click the **Convert** button.

Result: The original JSON document is now converted to an XML document.

Figure 657. Example: XML to JSON Operation Result



Conversion Details

- If the JSON document has more than one property on the first level, the converted XML document will have an additional root element called `<JSON>`.

  For example, the following JSON document:

```
{
   "personnel": {
    "person": [
      {"name": "Boss"},
      {"name": "Worker"}
    ]
  },
  "id":"personnel-id"
}
```

  it is converted to:

```
<?xml version="1.0" encoding="UTF-8"?>
<JSON>
  <personnel>
    <person>
      <name>Boss</name>
```

```
    </person>
    <person>
      <name>Worker</name>
    </person>
  </personnel>
  <id>personnel-id</id>
</JSON>
```

- If the JSON document is an array, the converted XML document will have a root element called `<array>` and for each item within the array, another `<array>` is created.

```
[
  {"name": "Boss"},
  {"name": "Worker"}
]
```

it is converted to:

```
<?xml version="1.0" encoding="UTF-8"?>
<array>
  <array>
    <name>Boss</name>
  </array>
  <array>
    <name>Worker</name>
  </array>
</array>
```

- If the name of a JSON property contains characters that are not valid in XML element names (for example, **$**), then the invalid characters will be escaped as its hexadecimal equivalent in the converted XML.

```
{"$id": "personnel-id"}
```

is converted to:

```
<_X24_id>personnel-id</_X24_id>
```

Related Information:

XML to JSON Converter

Online XML to JSON Converter

Attention:

For a simple ONLINE tool for converting a single XML file to JSON, or vice versa, go to: https://www.oxygenxml.com/xml_json_converter.html.

Converting XML to JSON in Oxygen

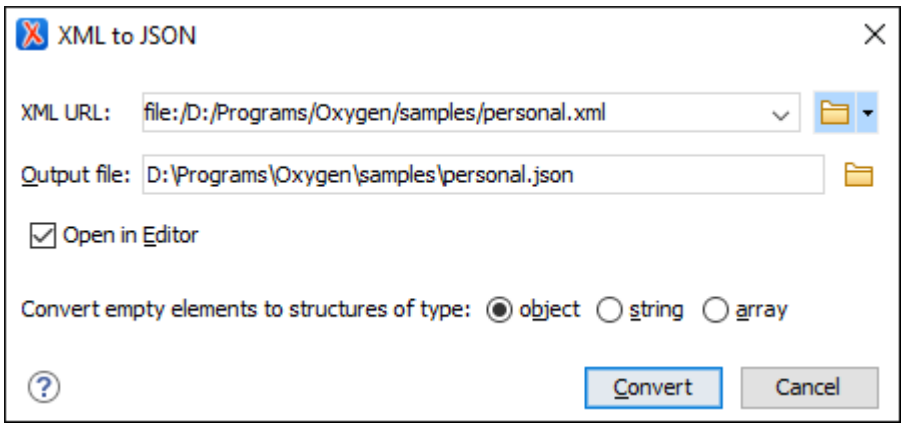
Oxygen XML Editor includes a useful and simple tool for converting XML files to JSON. The **XML to JSON** action for invoking the tool can be found in the **Tools > JSON Tools** menu.

To convert an XML document to JSON, follow these steps:

1. Select the **XML to JSON** action from the **Tools > JSON Tools** menu.

   Step Result: The **XML to JSON** dialog box is displayed:

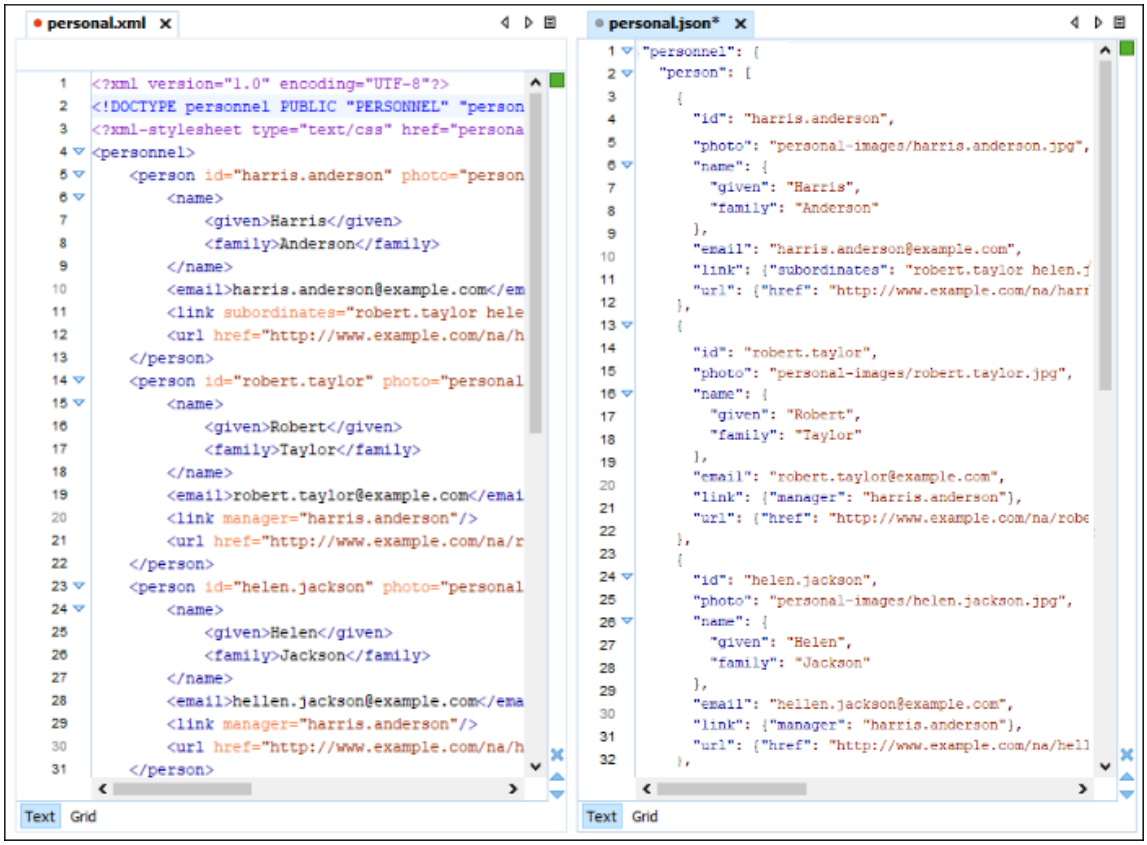
   Figure 658. XML to JSON Dialog Box

2. Choose or enter the **Input URL** of the XML document.
3. Choose the path of the **Output file** that will contain the resulting JSON document.
4. Select how you want empty elements to be converted (default is **object**).
5. Select the **Open in Editor** option to open the resulting JSON document in the main editing pane.
6. Click the **Convert** button.

Result: The original XML document is now converted to a JSON document.

Figure 659. Example: XML to JSON Operation Result



Conversion Details

- Some XML components are ignored (e.g. comments and processing instructions).
- If any elements contain attributes in the XML document, the attributes are converted to properties in the converted JSON document. If the XML document contains more than one element with the same name, they will be converted into an array of object in the converted JSON document.

  For example, the following XML document:

```
<personnel>
  <person id="person.one">
    <name>Boss</name>
  </person>
  <person id="person.two">
    <name>Worker</name>
  </person>
</personnel>
```

  it is converted to:

```
{
  "personnel": {
    "person": [
      {
```

```
        "id": "person.one",
        "name": "Boss"
      },
      {
        "id": "person.two",
        "name": "Worker"
      }
    ]
  }
}
```

- If the XML document contains elements with mixed content (text plus elements), the converted JSON document will contain a `#text` property with its value set as the text content. If there are multiple text nodes, the subsequent `#text` properties will contain a number (e.g. `#text1`, `#text2`). If there are multiple elements with the same name, the first property will have the element name and the subsequent properties will contain a number (e.g. b, b#1, b#2).

  ```
  <p>This <b>is</b> an <b>example</b>!</p>
  ```

  is converted to:

  ```
  {
    "p": {
      "#text": "This ",
      "b": "is",
      "#text1": " an ",
      "b#1": "example",
      "#text2": "!"
    }
  }
  ```

- If the XML document contains element names that contains hexadecimal codes (for example, if they were escaped during a JSON to XML conversion *(on page 1148)*), it will be converted to the normal character value in the converted JSON document.

  ```
  <_X24_id>personnel-id</_X24_id>
  ```

  is converted to:

  ```
  {"$id": "personnel-id"}
  ```

XSD to JSON Schema Converter

Discover the Oxygen JSON Editor!
Tailored for Working with JSON and JSON Schema Documents

Oxygen XML Editor includes a tool for converting an XML Schema file (XSD) to a JSON Schema file. The **XSD to JSON Schema** action for invoking the tool can be found in the **Tools > JSON Tools** menu. It requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor will present a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **XSD to JSON Schema** action will invoke the tool.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **XSD to JSON Schema** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **XSD to JSON Schema** dialog box is now available and can be selected from the **Tools > JSON Tools** menu.

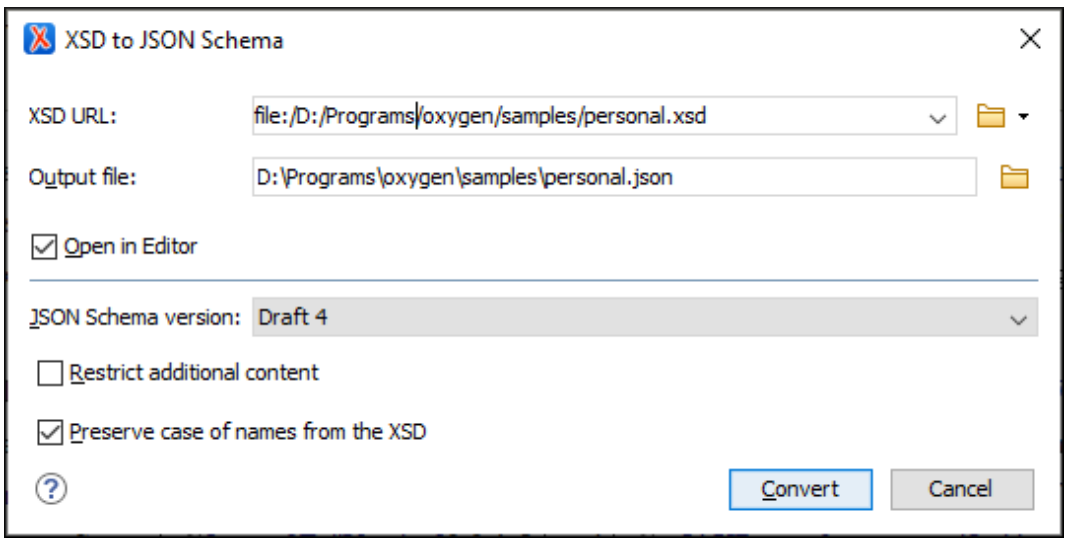
Converting XSD to JSON Schema

To convert an XML Schema (XSD) to a JSON Schema, follow these steps:

1. Select the **XSD to JSON Schema** action from the **Tools > JSON Tools** menu.

   Step Result: The **XSD to JSON Schema** dialog box is displayed:

   Figure 660. XSD to JSON Schema Dialog Box

2. In the **XSD URL** field, choose or enter the URL of the XML Schema document. The conversion supports XSD versions 1.0 and 1.1.
3. In the **Output file** field, choose the path for the resulting output file.
4. [Optional] You can select the **Open in Editor** option to open the resulting JSON Schema document in the main editing pane.
5. For the **JSON Schema version** option, choose the version of the resulting JSON schema. The possible choices are: **Draft 4**, **Draft 6**, **Draft 7**, **2019-09**, and **2020-12**.
6. [Optional] If you select the **Restrict additional content** option, then `additionalProperties` (for objects) and `additionalItems` (for arrays) will be set to `false` in the resulting schema. By default, these keys are not in the schema, meaning that providing additional content (according to the schema) is allowed.
7. [Optional] You can select the **Preserve case of names from the XSD** option if you want the names from the XSD to remain unchanged in the resulting JSON Schema. Otherwise, the default JAXB naming algorithm will be applied (for example, "`some.nAMe`" is changed to "`SomeNAMe`", or "`Some_oth3r_name`" is changed to "`SomeOth3RName`").
8. Click the **Convert** button.

Result: The original XSD document is now converted to a JSON Schema document. The resulting JSON Schema will be the specified draft and will contain:

- The `$id` of the schema, generated from XSD `targetNamespace`.
- The `$definitions` section, which declares `complex` and `enum` types.
- The `anyOf` section, which lists possible top-level elements as an array of objects.

Other Possible Results:

- If an XSD type extends another type, then its schema is combined with the schema of the base type using the `allOf` keyword.
- If an extension in XSD defines an element with the same name as an attribute in the base, a property named `rest` is generated to avoid name conflicts in JSON.
- If a property of a complex type is a collection property, the schema of the collection items will be wrapped in the JSON array schema.

Conversion Mappings

The following table lists the specific conversion mapping details.

XML Schema Type	JSON Schema Representation
anySimpleType	string, number, integer, boolean, null
anyType	string, number, integer, boolean, null, object, array
string	string
normalizedString	string
token	string
language	string
Name	string
NCName	string
ID	string
IDREF	string
IDREFS	array of strings
ENTITY	string
ENTITIES	array of strings
NMTOKEN	string
NMTOKENS	array of strings
boolean	boolean
base64Binary	array of integers
hexBinary	array of integers
float	number
decimal	number
integer	integer
nonPositiveInteger	integer

XML Schema Type	JSON Schema Representation
negativeInteger	integer
long	integer
int	integer
short	integer
byte	integer
nonNegativeInteger	integer
unsignedLong	integer
unsignedInt	integer
unsignedShort	integer
unsignedByte	integer
positiveInteger	integer
double	number
anyURI	string with "format":"uri"
QName	object with "namespaceURI", "localPart", "prefix"
duration	string
dateTime	string with "format":"date-time"
date	string with "format":"date"
time	string with "format":"time"

Conversion Limitations

In most cases, the conversion creates an equivalent schema, but there are some limitations:

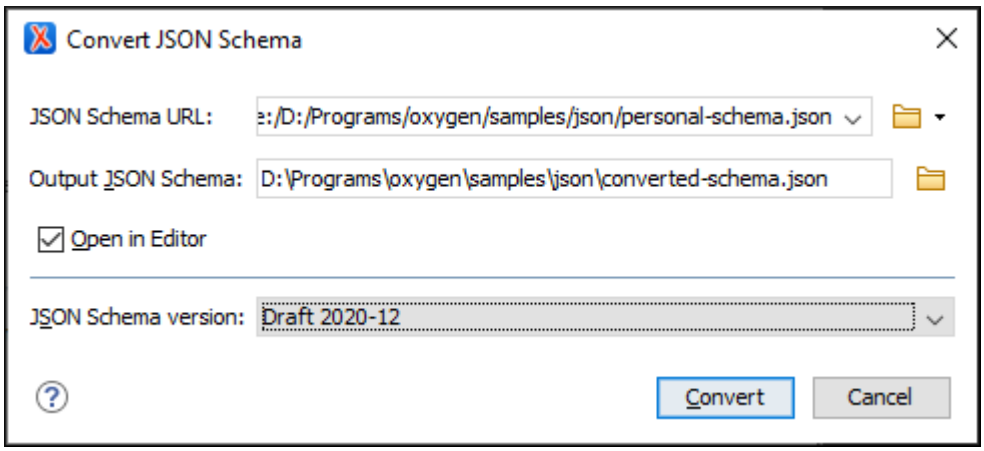
- Restrictions/facets are not taken into consideration when converting (`fractionDigits, pattern, totalDigits, whiteSpace`, `minInclusive`, `maxInclusive`, and the restrictions for length, except `enumeration`). However, extensions and indicators are properly converted (`minOccurs, maxOccurs, group, sequence, choice`).
- The `<documentation>` element is not converted into `<description>`.
- The `@substitutionGroup` attribute for an element that has no declared type becomes a reference to the element that can substitute it.
- The `@block` attribute is not taken into consideration during the conversion.

JSON Schema Converter

Oxygen XML Editor includes a tool for converting an older version of a JSON schema (Draft 4, 6, or 7) to the latest versions (2019-09 or 2020-12).

To convert a JSON schema, select **Convert JSON Schema** from the **Tools > JSON Tools** menu. The action opens a dialog box where you can configure some options for converting the JSON Schema.

Figure 661. Convert JSON Schema Dialog Box



The **Convert JSON Schema** dialog box includes the following fields and options:

JSON Schema URL

The URL of the JSON schema file. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the **Browse** drop-down list.

Output JSON Schema

The path to the folder where the converted JSON schema will be saved.

Open in Editor

If selected, the converted JSON schema is opened in the editor.

JSON Schema version

The version of the resulting JSON schema. The possible choices are: **Draft 2019-09** or **2020-12**.

You can click **Convert** at any point to generate the JSON Schema.

Conversion Notes

- The `$schema` declaration is changed according to the selected JSON schema version.
- The `definitions` keyword is converted to `$defs` and all the references are updated.
- The `dependencies` keyword is split into `dependentRequired` and `dependentSchemas`.
- The `items` keyword (tuple array) is converted to `prefixItems` (2020-12).
- The `additionalItems` keyword is converted to `items` (2020-12, only if `prefixItems` is present).
- The `exclusiveMinimum` and `exclusiveMaximum` keywords with boolean values (Draft 4) are removed.

- The `id` keyword (Draft 4) is converted to `$id`.
- The `$ref` keyword wrapped into 1-item `allOf` is unwrapped because the latest versions allow processing `$ref` along with other keywords.

OpenAPI Tester

Oxygen XML Editor includes a testing tool for *OpenAPI* files. The tool provides the ability to inspect OpenAPI request responses and to ensure that they work as expected. It can be used for OpenAPI 3.x in JSON or YAML format.

To use the tool, select **OpenAPI Tester** from the **Tools > JSON Tools** menu. This opens a dialog box where you can specify the location of the OpenAPI file that you want to test.

This tool requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor presents a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **OpenAPI Tester** action will invoke the tool.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

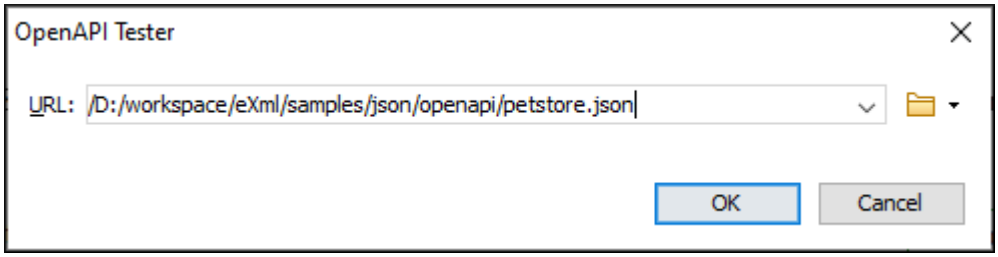
   Note:
   If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **OpenAPI Tester** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **OpenAPI Tester** dialog box is now available and can be selected from the **Tools > JSON Tools** menu.

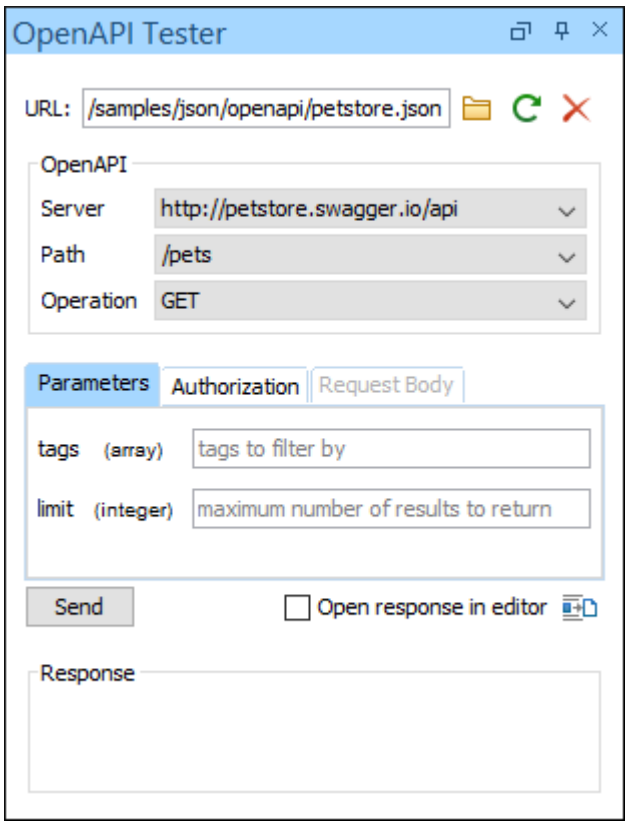
OpenAPI Tester Dialog Box

Figure 662. OpenAPI Tester Dialog Box



After selecting **OpenAPI Tester** from the **Tools > JSON Tools** menu, the **OpenAPI Tester** dialog box is displayed where you can select the URL for the OpenAPI document (either local or remote). After clicking **OK**, the **OpenAPI Tester** view becomes visible on the right side of the editor. The view can also be opened by selecting **OpenAPI Tester** from the **Window > Show View** menu.

Figure 663. OpenAPI Tester View



The tester loads the selected OpenAPI document and fills in the corresponding fields. The tester fields are as follows:

URL

The URL of the OpenAPI file. You can specify the path by using the text field or the **Browse** button. If you specify the path directly in the text field, you need to click the **Reload** button. You can use the **Clear** button if you want to remove all the content from the view.

Server

The list of servers defined by the OpenAPI document. The global "servers" array can be overridden on the path level or operation level. If it is not provided or is empty, the server URL defaults to "/".

Path

The list of individual endpoints (paths) in the API. The full request URL is constructed as `<server-url>/path`.

Operation

The list of HTTP operations supported by the selected path. OpenAPI 3.0 supports get, post, put, patch, delete, head, options, and trace.

Parameters tab

The definition of the parameters for the selected operation. OpenAPI 3.0 supports parameters passed via path, query string, headers, and cookies. The required parameters will be marked with a red asterisk. For array parameters, items must be separated by a comma.

Authorization tab

The list of available authentication types. The authentication data is persistent and can be removed from the contextual menu.

Request Body tab

The media type and the body of the request (if the selected operation allows it). For example, GET will not allow specifying a body since that HTTP method disallows it. Oxygen XML Editor will create a sample request body based on the JSON Schemas defined in the OpenAPI document. Usually, you just need to change a few values for the request to be valid.

Variables tab

The list of variables used for server templating (if applicable). Variables are indicated by {curly brackets} in the server URL.

Send button

Executes the request by creating a HTTP client with all the information extracted from the view.

Open response in editor

If selected, the response will be opened in the main editing pane.

 **Generate scenario test**

Creates a test scenario file in JSON format, based on the information extracted from the view. The file is then opened in the main editing pane, and can be used to **Run OpenAPI Test Scenario.** *(on page 2808)*

Response area

Initially this area is empty. After using the **Send** button, it presents the message received from the server in response to the request. The expected content type of the message is JSON. The

response status and possible errors that may occur are presented right below this area. The status has a green foreground for successful requests and a red foreground otherwise.

For more information about OpenAPI editing, testing, and documenting, watch our webinar:

https://www.youtube.com/embed/gKdabeh49Qk

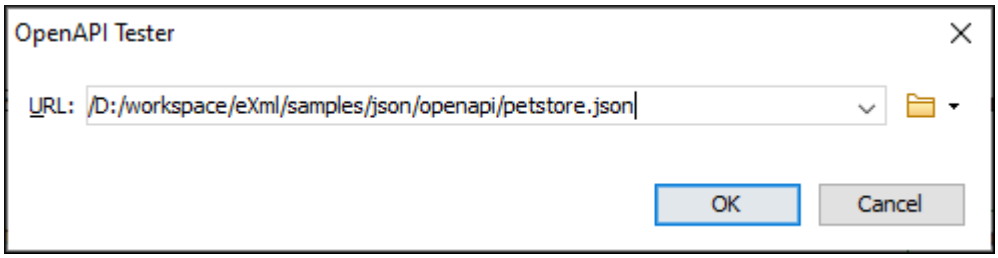
Run OpenAPI Test Scenarios

Oxygen XML Editor includes a testing tool for running *OpenAPI* test scenarios. The **Run OpenAPI Test Scenario** tool provides the ability to run a test suite for an OpenAPI document in JSON format. It performs the requests based on the specified OpenAPI document and the data entered in the test file, and then checks if the server responses are as expected.

Attention:
This tool requires the **OpenAPI Tester** add-on *(on page 2805)* (version 1.2.0 or newer) to be installed before it becomes available in the **JSON Tools** menu.

To use the tool, select **Run OpenAPI Test Scenario** from the **Tools > JSON Tools** menu. This opens a dialog box where you can specify the location of the test scenario file that you want to run.

Figure 664. Run OpenAPI Test Scenario Dialog Box



The scenario file must be valid according to the schema from here: `frameworks/json/schemas/openapi/scenario/openAPIScenario.jschema`. There is a default scenario file template available when creating new documents from templates *(on page 377)* and it can be found in the **Framework Templates > OpenAPI Test Scenario**. The template will automatically be validated against the schema.

For the scenario file, you have to specify the path of the OpenAPI document and the server where the requests are made. Then, for each test, you need to enter valid data for the required fields "**path**", "**operation**", "**expectedResponse**", and the optional fields "**description**", "**parameters**", "**authorization**", or "**body**".

After successfully running the test scenario, the results are displayed in a new JSON file.

Tip:
Oxygen XML Editor includes a specialized framework for editing and working with OpenAPI test scenario files *(on page 1465)*.

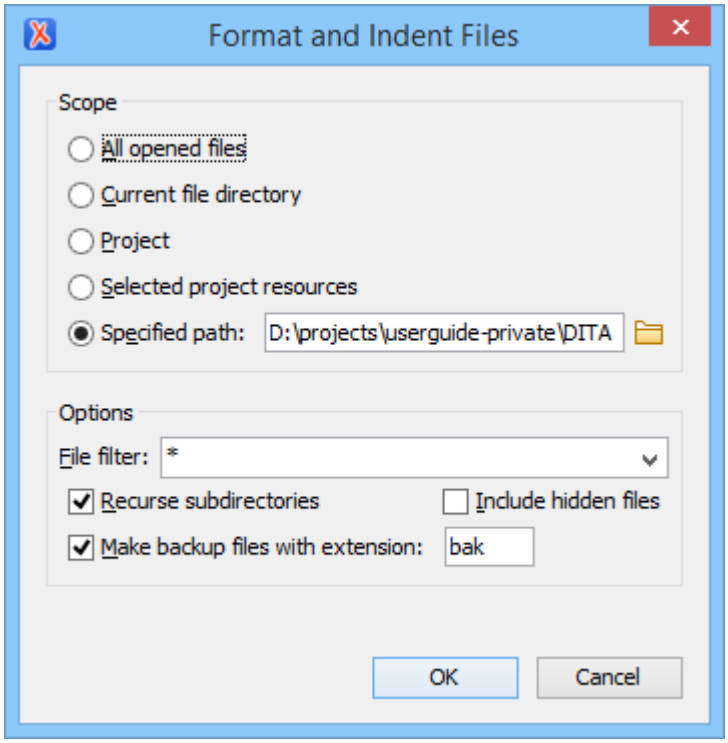
https://www.youtube.com/embed/gKdabeh49Qk

Format and Indent (Pretty-Print) Multiple Files

Oxygen XML Editor provides support for formatting and indenting (*pretty-print (on page 3422)*) multiple files at once. This action is available for any document in XML format, as well as for XQuery, CSS, JavaScript, and JSON documents.

To format and indent multiple files, use the **Format and Indent Files** action that is available in the contextual menu of the **Project** view *(on page 413)* or from the **Tools** menu. This opens the **Format and Indent Files** dialog box that allows you to configure options for the action.

Figure 665. Format and Indent Files Dialog Box



The **Scope** section allows you to choose from the following scopes:

- **All opened files** - The *pretty-print (on page 3422)* is performed in all opened files.
- **Directory of the current file** - All the files in the folder of the currently edited file.
- **Project files** - All files from the current project.
- **Selected project files** - The selected files from the current project.
- **Specified path** - the *pretty-print (on page 3422)* is performed in the files located at a specified path.

The **Options** section includes the following options:

- **File filter** - Allow you to filter the files from the selected scope.
- **Recurse subdirectories** - When selected, the *pretty-print (on page 3422)* is performed recursively for the specified scope. The one exception is that this option is ignored if the scope is set to **All opened files**.
- **Include hidden files** - When selected, the *pretty-print (on page 3422)* is also performed in the hidden files.
- **Make backup files with extension** - When selected, Oxygen XML Editor makes backup files of the modified files. The default extension is `.bak`, but you can change the extension as you prefer.

Generate Documentation

Oxygen XML Editor includes a tool for generating documentation for XSLT, XML Schema, XQuery, WSDL, JSON schema, and OpenAPI documents.

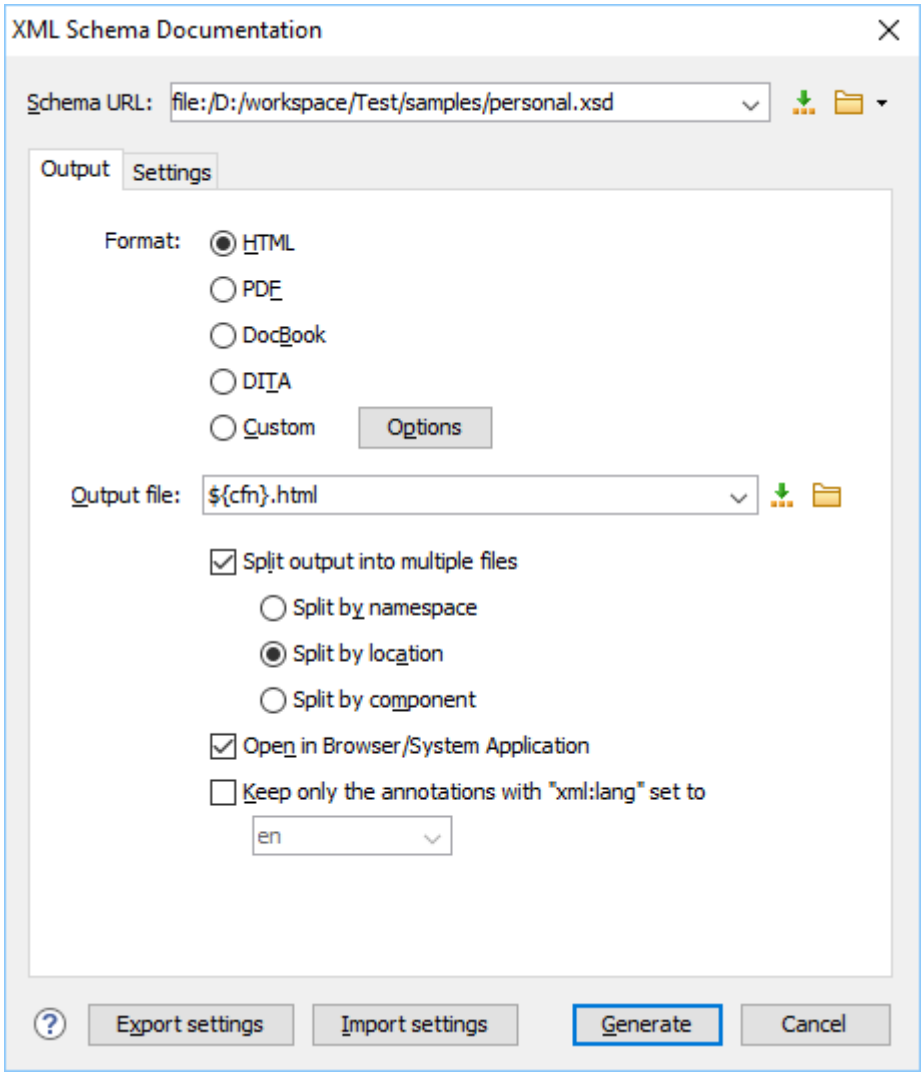
Generating Documentation for an XML Schema

Oxygen XML Editor can generate detailed documentation for the components of an XML Schema in HTML, PDF, DocBook, or other custom formats. You can select the components and the level of detail. The components are hyperlinked in both HTML and DocBook documents.

Note:
You can generate documentation for both XML Schema version 1.0 and 1.1.

To generate documentation for an XML Schema document, select **XML Schema Documentation** from the **Tools > Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the **Project** view *(on page 413)*. You can also open the tool by using the  **Generate Documentation** toolbar button.

Figure 666. XML Schema Documentation Dialog Box



The **Schema URL** field of the dialog box must contain the full path to the XML Schema (XSD) file that will have documentation generated. The schema may be a local or a remote file. You can specify the path to the schema by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in HTML output format *(on page 1029)*.
  - **PDF** - The documentation is generated in PDF output format *(on page 1032)*.
  - **DocBook** - The documentation is generated in DocBook output format *(on page 1032)*.
  - **DITA** - The documentation is generated in DITA output format *(on page 1032)*.
  - **Custom** - The documentation is generated in a custom output format *(on page 1032)*, allowing you to control the output. Click the **Options** button to open a **Custom format options** dialog box where you can specify a custom stylesheet for creating the output. There is also an option to

Copy additional resources to the output folder and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.

- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the  **Insert Editor Variables** button or the options in the  **Browse** drop-down menu.
- **Split output into multiple files** - Instructs the application to split the output into multiple files. You can choose to split them by namespace, location, or component name.
- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type. For DITA and DocBook documents, this option appears as **Open in Editor** and the result will be opened in Oxygen XML Editor (in the current editor).

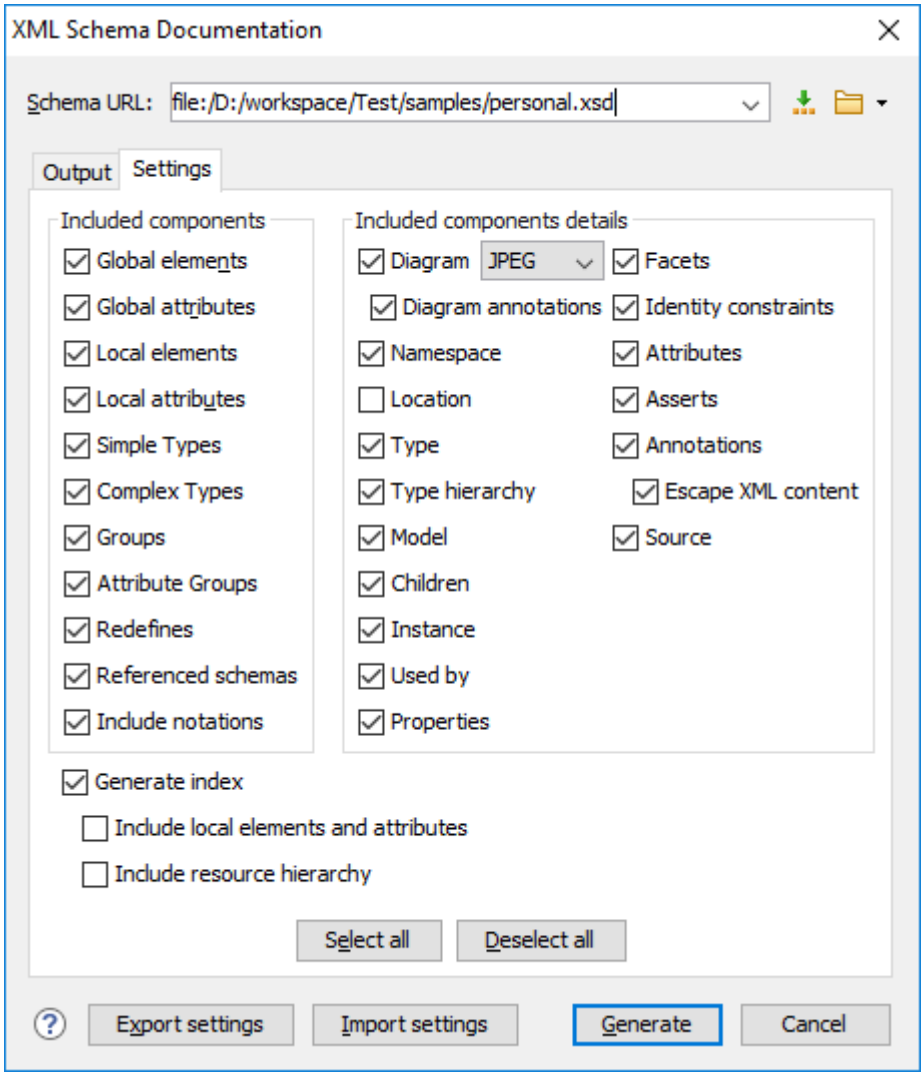
Note:
To set the browser or system application that will be used, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

- **Keep only the annotations with xml:lang set to** - The generated output will contain only the annotations with the `@xml:lang` attribute set to the selected language. If you choose a primary language code (for example, **en** for English), this includes all its possible variations (**en-us**, **en-uk**, etc.).

Settings Tab

When you generate documentation for an XML schema you can choose what components to include in the output and the details to be included in the documentation.

Figure 667. Settings Tab of the XML Schema Documentation Dialog Box



The **Settings** tab allows you to choose whether or not to include the following components: **Global elements**, **Global attributes**, **Local elements**, **Local attributes**, **Simple Types**, **Complex Types**, **Groups**, **Attribute Groups**, **Redefines**, **Referenced schemas**, **Include notations**.

You can choose whether or not to include the following other details:

- **Diagram** - Displays the diagram for each component. You can choose the image format (JPEG, PNG, GIF, SVG) to use for the diagram section. The generated diagrams are dependent on the options from the Schema Design Properties *(on page 206)* page.
- **Diagram annotations** - This option controls whether or not the annotations of the components presented in the diagram sections are included.
- **Namespace** - Displays the namespace for each component.
- **Location** - Displays the schema location for each component.
- **Type** - Displays the component type if it is not an anonymous one.
- **Type hierarchy** - Displays the types hierarchy.
- **Model** - Displays the model (sequence, choice, all) presented in BNF form. The separator characters that are used depend upon the information item used:

    - **xs:all** - Its children will be separated by space characters.
    - **xs:sequence** - Its children will be separated by comma characters.
    - **xs:choice** - Its children will be separated by | characters.
- **Children** - Displays the list of component's children.
- **Instance** - Displays an XML instance generated based on each schema element.
- **Used by** - Displays the list of all the components that reference the current one. The list is sorted by component type and name.
- **Properties** - Displays some of the component's properties.
- **Facets** - Displays the facets for each simple type.
- **Identity constraints** - Displays the identity constraints for each element. For each constraint there are presented the name, type (unique, key, keyref), reference attribute, selector and field(s).
- **Attributes** - Displays the attributes for the component. For each attribute there are presented the name, type, fixed or default value, usage and annotation.
- **Asserts** - Displays the **assert** elements defined in a complex type. The test, XPath default namespace, and annotation are presented for each assert.
- **Annotations** - Displays the annotations for the component. If you choose **Escape XML Content**, the XML tags are present in the annotations.
- **Source** - Displays the text schema source for each component.
- **Generate index** - Displays an index with the components included in the documentation.
    - **Include local elements and attributes** - If selected, local elements and attributes are included in the documentation index.
    - **Include resource hierarchy** - Specifies whether or not the resource hierarchy for an XML Schema documentation is generated. It is deselected by default.

Export settings - Save the current settings in a settings file for further use (for example, if you need the exported settings file for generating the documentation from the command-line interface).

Import settings - Reloads the settings from the exported file.

Generate - Use this button to generate the XML Schema documentation.

Tip:
This function can be executed from an automated command-line script, for more details, see Scripting Oxygen *(on page 3383)*.

Related Information:
Customizing PDF or DocBook Output of Generated XML Schema Documentation *(on page 1033)*

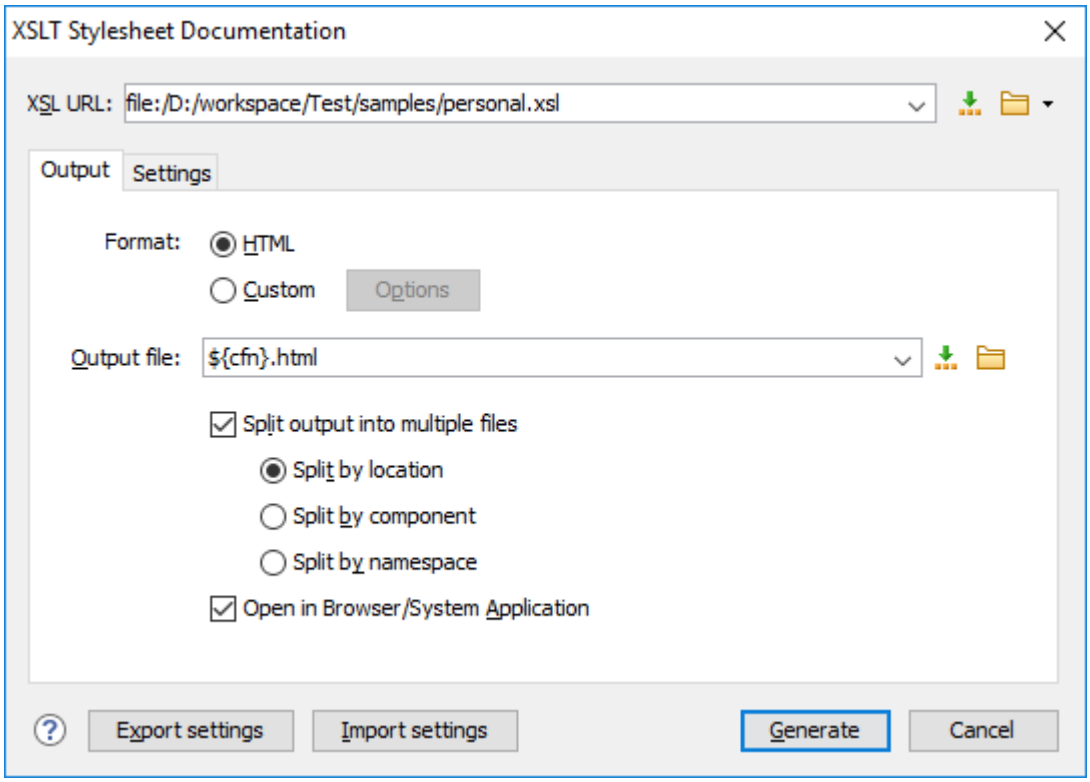
Generating Documentation for an XSLT Stylesheet

You can use Oxygen XML Editor to generate detailed documentation in HTML format for the elements (top-level elements whose names are in the XSLT namespace) of an XSLT stylesheet. You can select what XSLT elements to include in the generated documentation and also the level of details to present for each of them.

The elements are hyperlinked. To generate documentation in a custom output format *(on page 944)*, you can edit the XSLT stylesheet used to generate the documentation, or create your own stylesheet.

To open the **XSLT Stylesheet Documentation** dialog box, select **XSLT Stylesheet Documentation** from the **Tools > Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the **Project** view *(on page 413)*. You can also open the tool by using the **Generate Documentation** toolbar button.

Figure 668. XSLT Stylesheet Documentation Dialog Box



The **XSL URL** field of the dialog box must contain the full path to the XSL Stylesheet file you want to generate documentation for. The stylesheet may be a local or a remote file. You can specify the path to the stylesheet by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in HTML output format *(on page 941)*.
  - **Custom** - The documentation is generated in a custom output format *(on page 944)*, allowing you to control the output. Click the **Options** button to open a **Custom format options** dialog box *(on page 945)* where you can specify a custom stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the

additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.

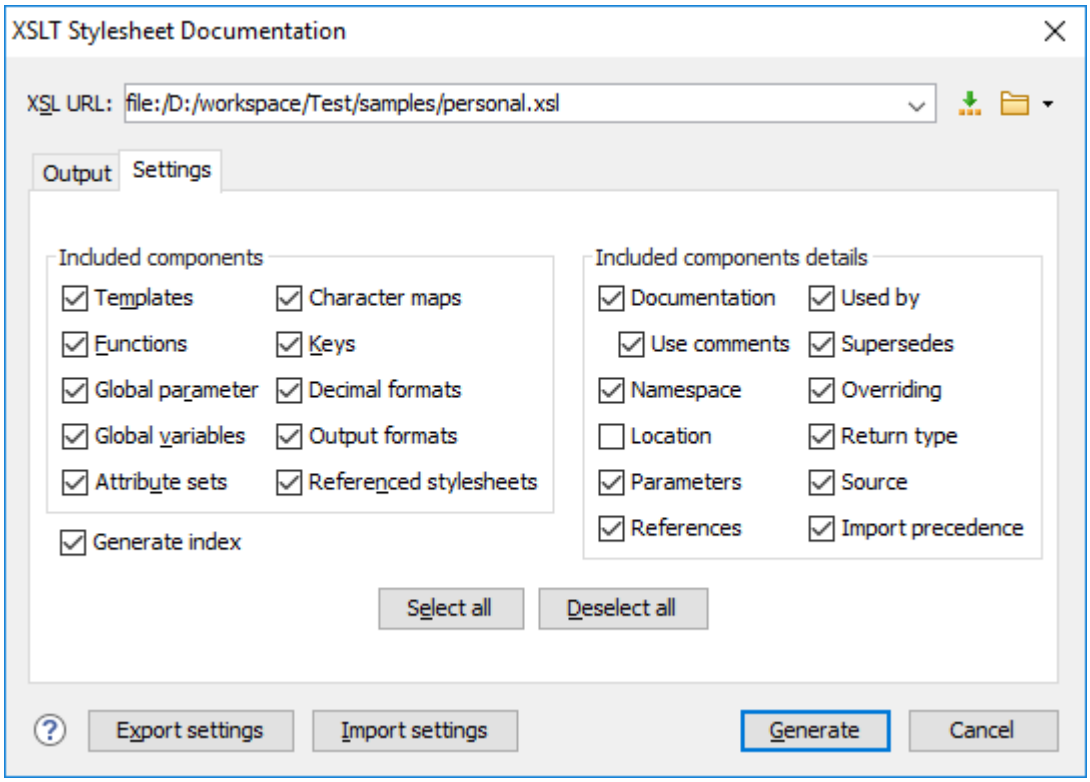
- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.
- **Split output into multiple files** - Instructs the application to split the output into multiple files. For large XSLT stylesheets, choosing another split criterion may generate smaller output files, providing faster documentation browsing. You can choose to split them by namespace, location, or component name.
- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type.

> **Note:**
> To set the browser or system application that will be used, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

Settings Tab

When you generate documentation for an XSLT stylesheet you can choose what XSLT elements to include in the output (templates, functions, global parameters, global variables, attribute sets, character maps, keys, decimal formats, output formats, XSLT elements from referenced stylesheets) and the details to include in the documentation.

Figure 669. Settings Tab of the XSLT Stylesheet Documentation Dialog Box



The **Settings** tab allows you to choose whether or not to include the following components: **Templates**, **Functions**, **Global parameters**, **Global variables**, **Attribute sets**, **Character maps**, **Keys**, **Decimal formats**, **Output formats**, **Referenced stylesheets**.

You can choose whether or not to include the following other details:

- **Documentation** - Shows the documentation for each XSLT element. For HTML format, the user-defined data elements that are recognized and transformed in documentation blocks of the XSLT elements they precede, are the ones from the following schemas:
  - Oxygen XML Editor built-in XSLT documentation schema.
  - A subset of DocBook 5 elements. The recognized elements are: *section*, *sect1* to *sect5*, *emphasis*, *title*, *ulink*, *programlisting*, *para*, *orderedlist*, *itemizedlist*.
  - A subset of DITA elements. The recognized elements are: *concept*, *topic*, *task*, *codeblock*, *p*, *b*, *i*, *ul*, *ol*, *pre*, *sl*, *sli*, *step*, *steps*, *li*, *title*, *xref*.
  - Full XHTML 1.0 support.
  - XSLStyle documentation environment. XSLStyle uses DocBook or DITA languages inside its own user-defined data elements. The supported DocBook and DITA elements are the ones mentioned above.
  - DOXSL documentation *framework (on page 3420)*. Supported elements are: *codefrag*, *description*, *para*, *docContent*, *documentation*, *parameter*, *function*, *docSchema*, *link*, *list*, *listitem*, *module*, *parameter*, *template*, *attribute-set*.

    Other XSLT documentation blocks that are not recognized will just be serialized inside an HTML *pre* element. You can change this behavior by using a custom format *(on page 944)* instead of the built-in HTML format *(on page 941)* and providing your own XSLT stylesheets.
- **Use comments** - Controls whether or not the comments that precede an XSLT element is treated as documentation for the element they precede. Comments that precede or succeed the *xsl:stylesheet* element, are treated as documentation for the whole stylesheet. Note that comments that precede an import or include directive are not collected as documentation for the imported/included module. Also, comments from within the body of the XSLT elements are not collected at all.
- **Namespace** - Shows the namespace for named XSLT elements.
- **Location** - Shows the stylesheet location for each XSLT element.
- **Parameters** - Shows parameters of templates and functions.
- **References** - Shows the named XSLT elements that are referenced from within an element.
- **Used by** - Shows the list of all the XSLT elements that reference the current named element.
- **Supersedes** - Shows the list of all the XSLT elements that are superseded the current element.
- **Overriding** - Shows the list of all the XSLT elements that override the current element.
- **Return type** - Shows the return type of the function.
- **Source** - Shows the text stylesheet source for each XSLT element.
- **Import precedence** - Shows the computed import precedence as declared in the XSL transformation specifications.
- **Generate index** - Creates an index with all the XSLT elements included in the documentation.

Export settings - Save the current settings in a settings file for further use (for example, if you need the exported settings file for generating the documentation from the command-line interface).

Import settings - Reloads the settings from the exported file.

Generate - Use this button to generate the XSLT documentation.

Tip:
This function can be executed from an automated command-line script, for more details, see Scripting Oxygen *(on page 3383)*.

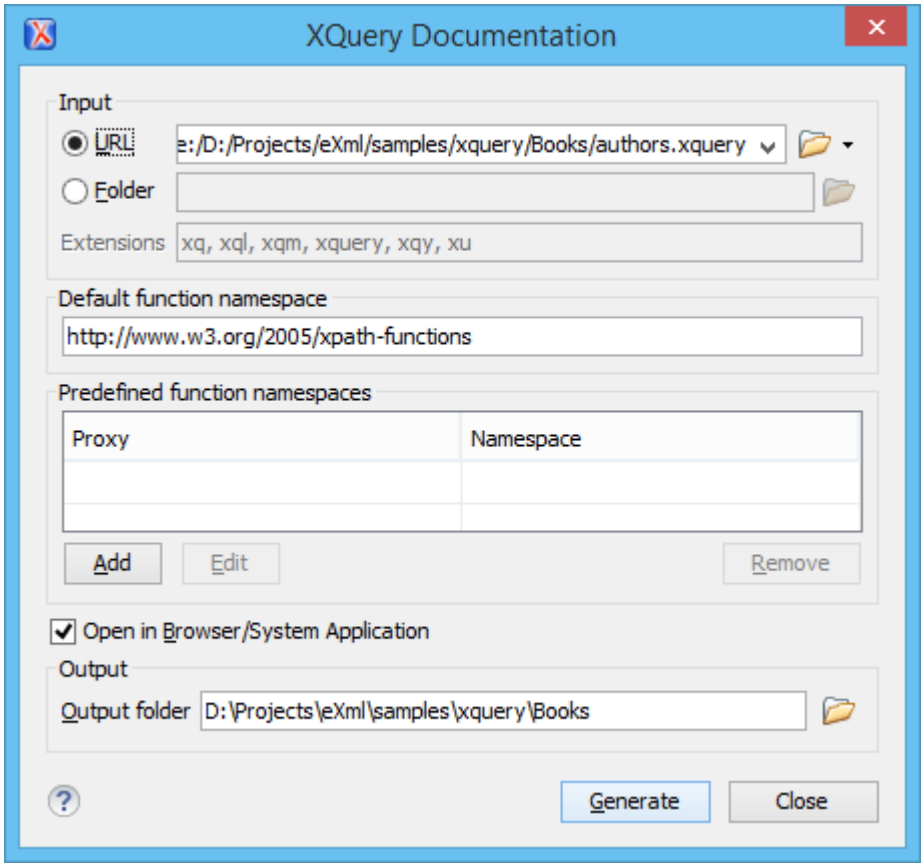
Related Information:
XSLT Stylesheet Component Documentation Support *(on page 925)*

Generating HTML Documentation for an XQuery Document

To generate HTML documentation for an XQuery document, use the **XQuery Documentation** dialog box. It is opened with the **XQuery Documentation** action that is available from the **Tools > Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the **Project** view *(on page 413)*. You can also open the tool by using the **Generate Documentation** toolbar button.

The dialog box allows you to configure a set of parameters for the process of generating the HTML documentation.

Figure 670. XQuery Documentation Dialog Box



The following options are available:

- **Input** - The full path to the XQuery file must be specified in one of the two fields in this section:
  - **URLFile** - The URL of the file to be used for generating the documentation.
  - **Folder** - The directory that contains the files to be used for generating the documentation. You can also specify the XQuery file extensions to be searched for in the specified directory.
- **Default function namespace** - Optional URI for the default namespace for the submitted XQuery.
- **Predefined function namespaces** - Optional, engine-dependent, predefined namespaces that the submitted XQuery refers to. They allow the conversion to generate annotation information to support the presentation component hypertext linking (only if the predefined modules have been loaded into the local xqDoc XML repository).
- **Open in Browser/System Application** - Select this option if you want the result to be opened in the system application associated with that file type.

> **Note:**
> To set the browser or system application that will be used, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

- **Output** - Allows you to specify where the generated documentation is saved on disk.

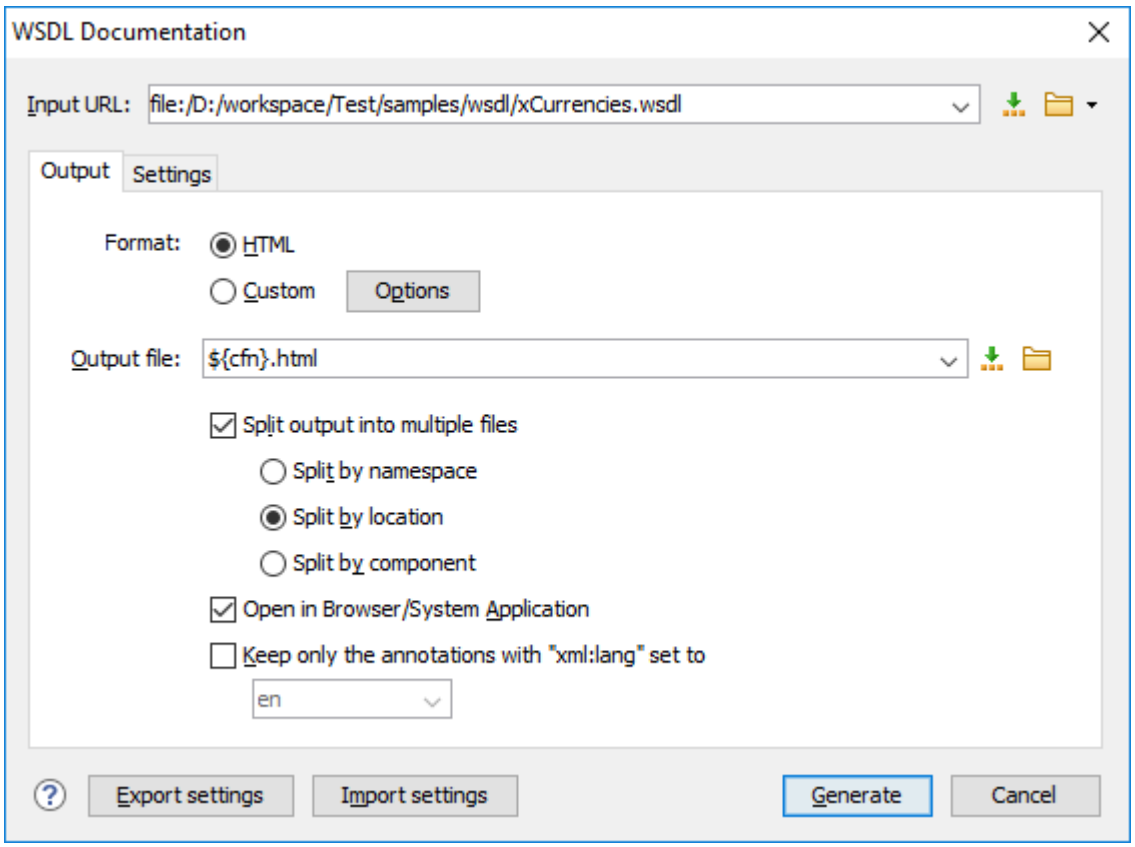
Generating Documentation for WSDL Documents (Deprecated)

You can use Oxygen XML Editor to generate detailed documentation for the components of a WSDL document in HTML format. You can select the WSDL components to include in your output and the level of details to present for each of them. Also, the components are hyperlinked. You can also generate the documentation in a custom output format *(on page 1085)* by using a custom stylesheet.

Note:
The WSDL documentation includes the XML Schema components that belong to the internal or imported XML schemas.

To generate documentation for a WSDL document, select **WSDL Documentation** from the **Tools > Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the **Project** view *(on page 413)*. You can also open the tool by using the **Generate Documentation** toolbar button.

Figure 671. WSDL Documentation Dialog Box



The **Input URL** field of the dialog box must contain the full path to the WSDL document that you want to generate documentation for. The WSDL document may be a local or a remote file. You can specify the path to the WSDL file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in HTML output format *(on page 1084)*.
  - **Custom** - The documentation is generated in a custom output format *(on page 1085)*, allowing you to control the output. Click the **Options** button to open a **Custom format options** dialog box where you can specify a custom stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.
- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.
- **Split output into multiple files** - Instructs the application to split the output into multiple files. For large WSDL documents, choosing a different split criterion may generate smaller output files providing a faster documentation browsing. You can choose to split them by namespace, location, or component name.
- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type.

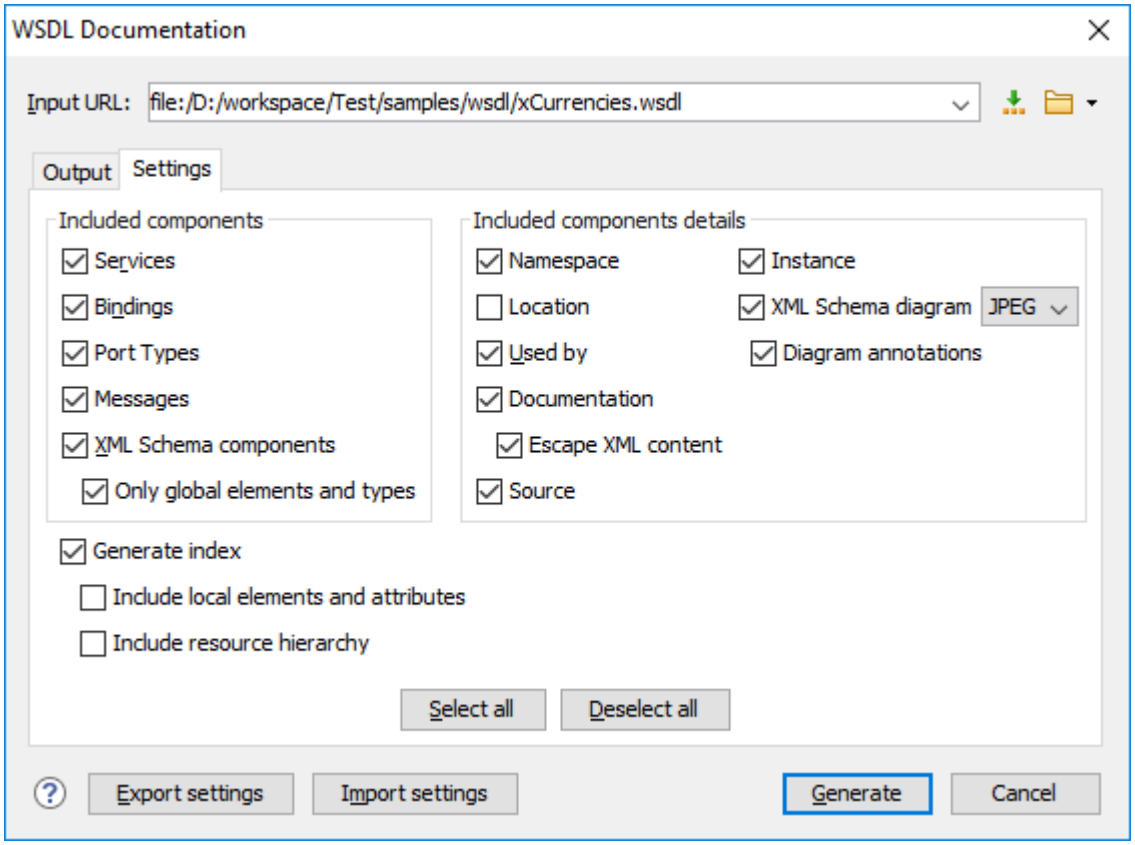
  > **Note:**
  > To set the browser or system application that will be used, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

- **Keep only the annotations with xml:lang set to** - The generated output will contain only the annotations with the `@xml:lang` attribute set to the selected language. If you choose a primary language code (for example, **en** for English), this includes all its possible variations (**en-us**, **en-uk**, etc.).

Setting Tab

When you generate documentation for a WSDL document, you can choose what components to include in the output and the details to be included in the documentation.

Figure 672. Settings Tab of the WSDL Documentation Dialog Box



The **Settings** tab allows you to choose whether or not to include the following:

- **Components**
  - **Services** - Specifies whether or not the generated documentation includes the WSDL services.
  - **Bindings** - Specifies whether or not the generated documentation includes the WSDL bindings.
  - **Port Types** - Specifies whether or not the generated documentation includes the WSDL port types.
  - **Messages** - Specifies whether or not the generated documentation includes the WSDL messages.
  - **XML Schema Components** - Specifies whether or not the generated documentation includes the XML Schema components.
  - **Only global elements and types** - Specifies whether or not the generated documentation includes only global elements and types.
- **Component Details**
  - **Namespace** - Presents the namespace information for WSDL or XML Schema components.
  - **Location** - Presents the location information for each WSDL or XML Schema component.
  - **Used by** - Presents the list of components that reference the current one.
  - **Documentation** - Presents the component documentation. If you choose **Escape XML Content**, the XML tags are presented in the documentation.
  - **Source** - Presents the XML fragment that defines the current component.
  - **Instance** - Generates a sample XML instance for the current component.

Note:
This option applies to the XML Schema components only.

- **XML Schema Diagram** - Displays the diagram for each XML Schema component. You can choose the image format (JPEG, PNG, GIF, SVG) to use for the diagram section.
- **Diagram annotations** - Specifies whether or not the annotations of the components presented in the diagram sections are included.

- **Generate index** - Displays an index with the components included in the documentation.
  - **Include local elements and attributes** - If selected, local elements and attributes are included in the documentation index.
  - **Include resource hierarchy** - Specifies whether or not the resource hierarchy for an XML Schema documentation is generated. It is deselected by default.

Export settings - Save the current settings in a settings file for further use (for example, if you need the exported settings file for generating the documentation from the command-line interface).

Import settings - Reloads the settings from the exported file.

Generate - Use this button to generate the WSDL documentation.

Tip:
This function can be executed from an automated command-line script, for more details, see Scripting Oxygen *(on page 3383)*.

Generating JSON Schema Documentation

Oxygen XML Editor includes a tool for generating documentation for a JSON Schema file in HTML format. To generate JSON Schema documentation, select **JSON Schema Documentation** from the **Tools > Generate Documentation** menu. You can also open the tool by using the  **Generate Documentation** toolbar button. This opens a dialog box where you can specify the location of the JSON Schema file and HTML output file.

This tool requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor presents a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **JSON Schema Documentation** action will invoke the tool.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

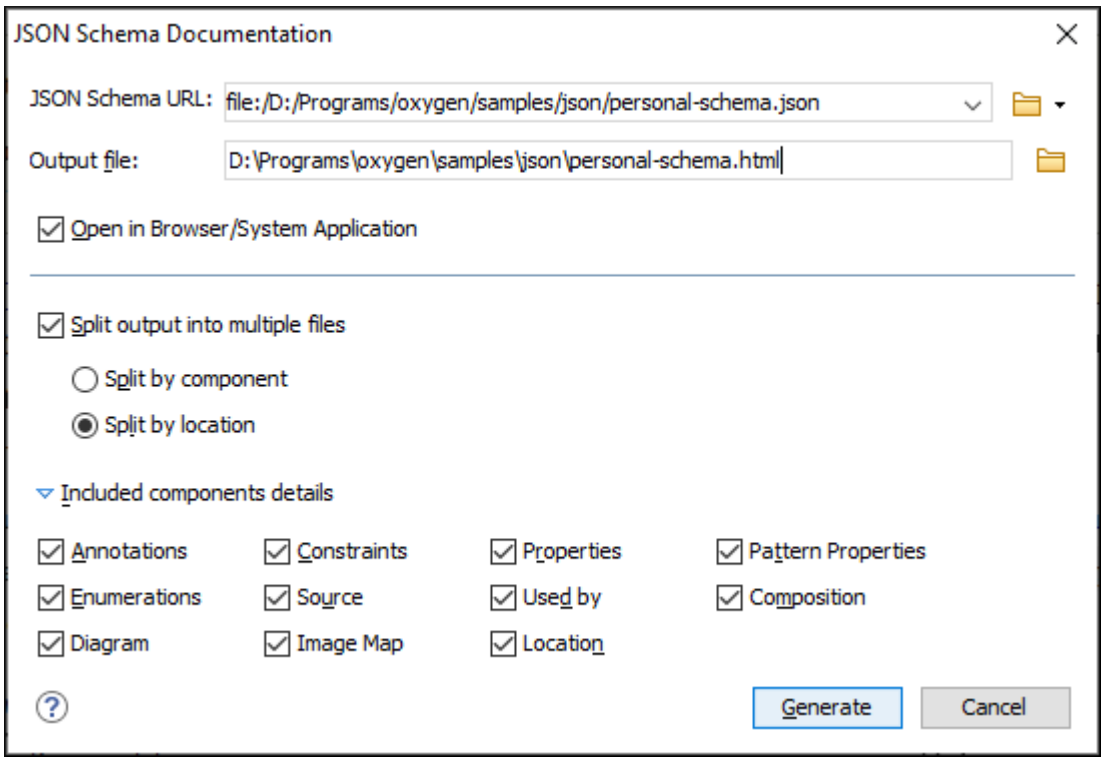
   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **JSON Schema Documentation** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

Result: The **JSON Schema Documentation** dialog box is now available and can be selected from the **Tools > Generate Documentation** menu.

JSON Schema Documentation Dialog Box

Figure 673. JSON Schema Documentation Dialog Box



The **JSON Schema Documentation** dialog box includes the following fields and options:

JSON Schema URL

The URL of the JSON Schema file. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the  **Browse** drop-down list. The tool supports schemas with versions *Draft 04*, *06*, *07* and, starting with version 4.0.0 of the add-on, *2019-09* and *2020-12*.

Output file

The path to the folder where the generated HTML file will be saved.

Split output into multiple files

If selected, the application splits the output into multiple files. You can choose between splitting them by **component** name or **location**.

Open in Browser/System Application

If selected, the generated result is opened in the system application associated with the output file type (HTML).

Included component details

This section can be used to specify whether or not the following components are shown in the generated documentation:

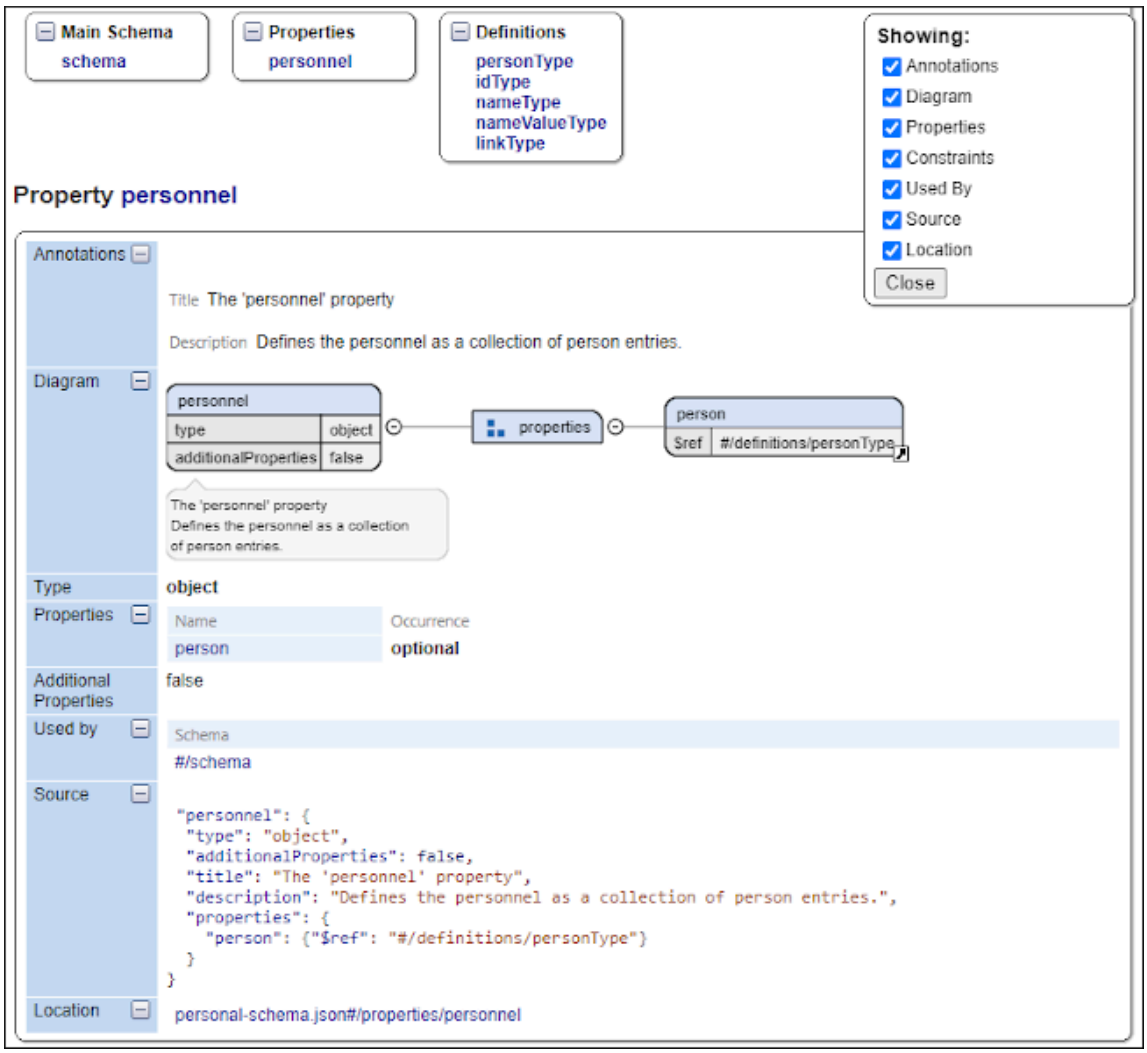
- **Annotations** - Displays the annotations (title, description) for each component (property or definition).
- **Constraints** - Displays the schema constraints for each component, according to its type.
- **Properties** - Displays the `properties` of an Object Schema.
- **Pattern Properties** - Displays the `patternProperties` of an Object Schema.
- **Enumerations** - Displays the enumerated values, if specified in the schema.
- **Source** - Displays the text schema source for each component.
- **Used By** - Displays the list of all the components that reference the current definition.
- **Composition** - Displays the `oneOf`, `anyOf`, and `allOf` compositors that are used for combining schemas.
- **Diagram** - Displays the diagram image for each component. The diagrams are generated according to the options specified in the **Schema Design** preferences page *(on page 206)*. Diagrams are also generated for components within schemas from referenced files.
- **Image Map** - Diagrams will include hyperlinks that navigate to each particular component.
- **Location** - Displays the schema location for each component.

You can click **Generate** at any point to generate the JSON Schema documentation.

Generated JSON Schema Documentation in HTML Format

After generating the JSON Schema documentation, it is presented in a visual diagram style with various sections, hyperlinks, and options.

Figure 674. JSON Schema Documentation Example Opened in a Browser



The generated documentation includes a Table of Contents on the left pane with links to particular sections in the right pane. You can collapse or expand details by using the **Showing** options or the **Collapse** or **Expand** buttons.

Generating OpenAPI Documentation

Oxygen XML Editor includes a tool for generating documentation for *OpenAPI* 3.0, or 3.1 documents in either JSON or YAML format, including annotations and cross references. The documentation displays information about the servers, paths, components and tags defined in the OpenAPI documents and you can choose whether the output is presented in HTML (with various sections, hyperlinks, and filtering options), DITA, or PDF.

Quick Installation

You can drag the following **Install** button and drop it into the main editor in **Oxygen** to quickly initiate the installation process:

Install

Manual Installation

To manually install it the add-on, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.

   > **Note:**
   > If you have issues connecting to the default update site, you can download the add-on package, unzip it, then use the **Browse for local files** action in the **Install new add-ons** dialog box to locate the downloaded `addon.xml` file.

3. Select the **OpenAPI Documentation Generator** add-on and click **Next**.
4. Read the end-user license agreement. Then select the **I accept all terms of the end-user license agreement** option and click **Finish**.
5. Restart the application.

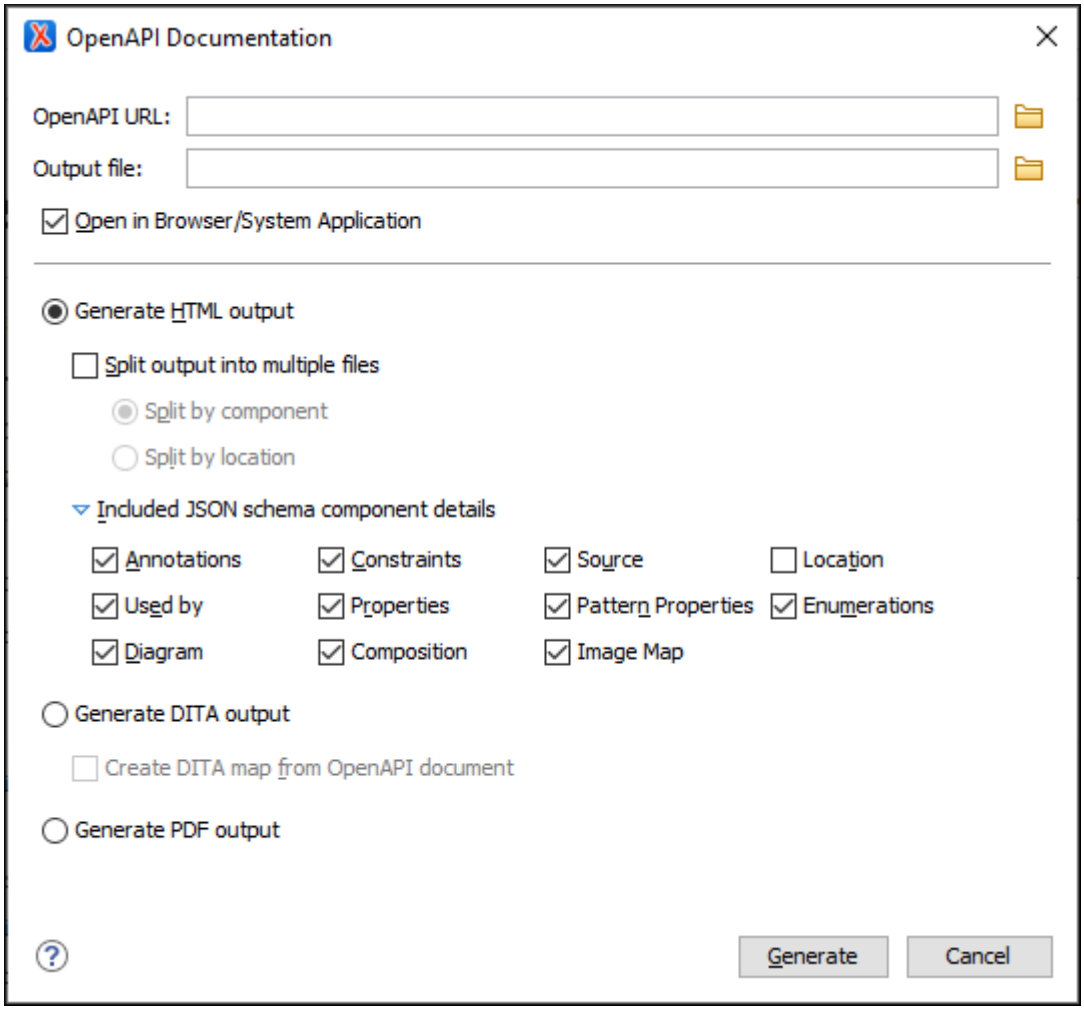
Result: The **OpenAPI Documentation** dialog box is now available and can be selected from the **Tools > Generate Documentation** menu.

Generating OpenAPI Documentation

To generate OpenAPI documentation, select **OpenAPI Documentation** from the **Tools > Generate Documentation** menu. This opens a dialog box where you can specify the location of the OpenAPI file and the output file, as well as the type of output to generate.

This tool requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor presents a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **OpenAPI Documentation** action will invoke the tool.

Figure 675. OpenAPI Documentation Dialog Box



The **OpenAPI Documentation** dialog box includes the following fields and options:

OpenAPI URL

The URL of the OpenAPI file (it can be in either JSON or YAML format). You can specify the path by using the text field or the browsing button ( ).

Output file

The path to the folder where the generated file(s) will be saved.

Generate HTML output

Choose this option to generate the output in HTML format.

Split output into multiple files

If selected, the application splits the output into multiple files. You can choose between splitting them by **component** name or **location**.

Included JSON schema component details

This section can be used to specify whether or not details about the following components that belong to internal or imported schemas are shown in the generated documentation:

- **Annotations** - Displays the annotations (title, description) for each component (property or definition).
- **Constraints** - Displays the schema constraints for each component, according to its type.
- **Source** - Displays the text schema source for each component.
- **Location** - Displays the schema location for each component.
- **Used By** - Displays the list of all the components that reference the current definition.
- **Properties** - Displays the `properties` of an Object Schema.
- **Pattern Properties** - Displays the `patternProperties` of an Object Schema.
- **Enumerations** - Displays the enumerated values, if specified in the schema.
- **Diagram** - Displays the diagram image for each component. The diagrams are generated according to the options specified in the **Schema Design** preferences page *(on page 206)*. Diagrams are also generated for components within schemas from referenced files.
- **Composition** - Displays the `oneOf`, `anyOf`, and `allOf` compositors that are used for combining schemas.

Generate DITA output

Choose this option to generate the output in DITA format.

Create DITA map from OpenAPI document

If selected, the application generates a DITA map with referenced topics based on the input OpenAPI document.

Generate PDF output

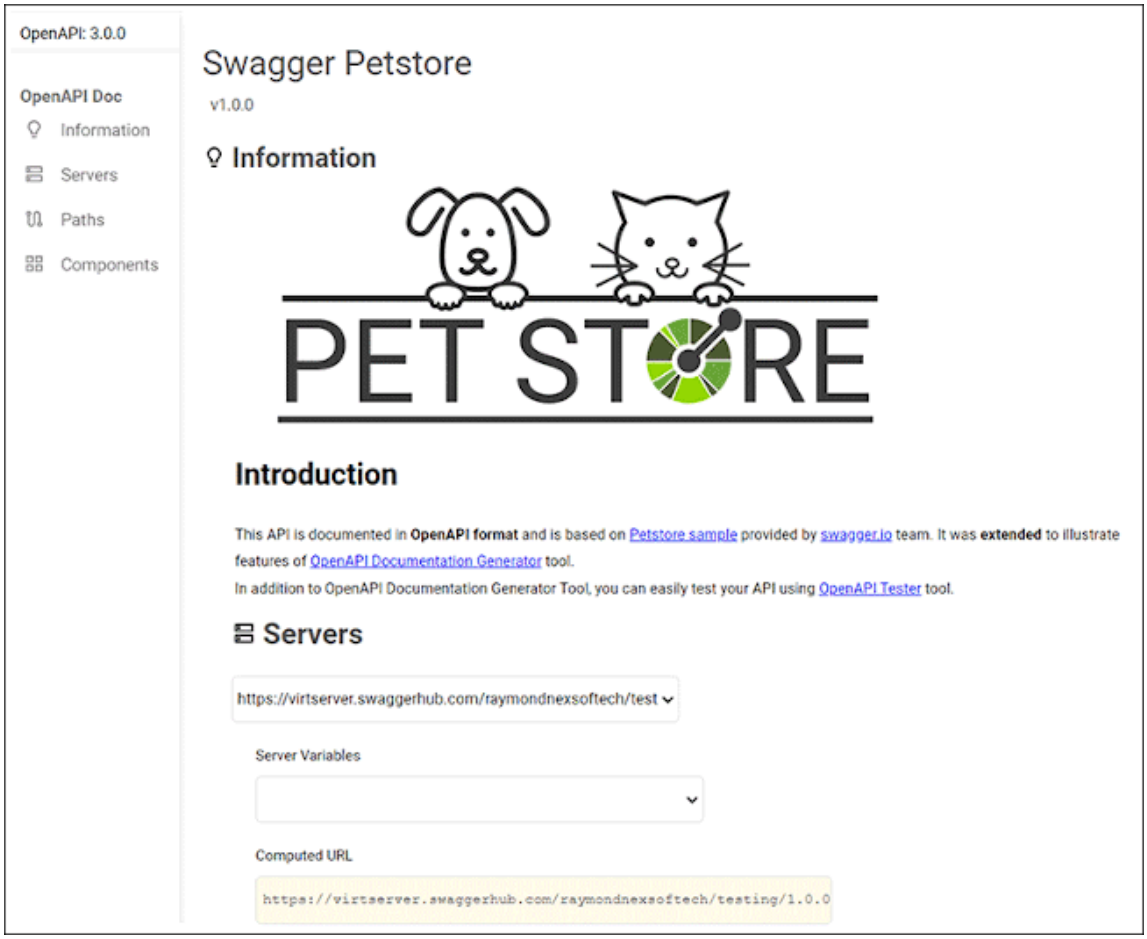
Choose this option to generate the output in PDF format.

Click the **Generate** button to generate the OpenAPI documentation.

Generated OpenAPI Documentation in HTML Format

When generating the OpenAPI documentation in HTML format, it is presented in the browser with various sections, hyperlinks, and options.

Figure 676. OpenAPI Documentation Example



The generated documentation includes a Table of Contents on the left pane with links to particular sections in the right pane. You can collapse or expand details by using the **Collapse** or **Expand** buttons.

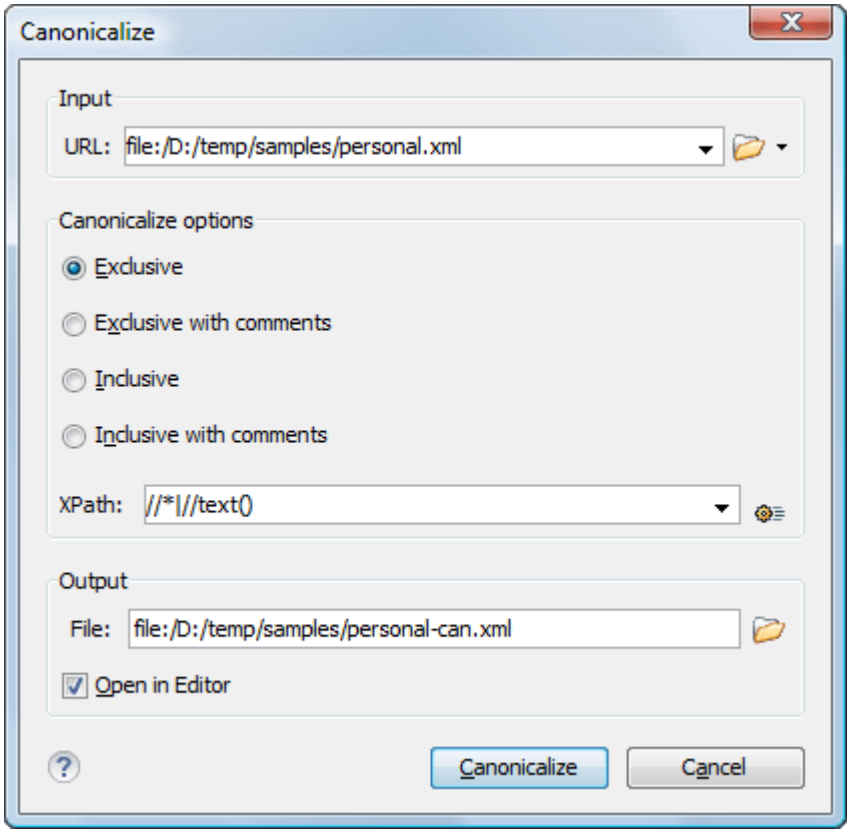
https://www.youtube.com/embed/gKdabeh49Qk

Canonicalizing Files

You can select the *canonicalization (on page 3418)* algorithm to be used for a document from the dialog box that is displayed by using the **Canonicalize** action that is available from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu.

Figure 677. Canonicalization Settings Dialog Box



The **Canonicalize** dialog box allows you to set the following options:

- **Input URL** - Available if the **Canonicalize** action was selected from the **Tools** menu. It allows you to specify the location of the input file.
- **Exclusive** - If selected, the exclusive (uncommented) *canonicalization (on page 3418)* method is used.

> **Note:**
> *Exclusive Canonicalization* just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents (or you need self-signed structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.

- **Exclusive with comments** - If selected, the exclusive with comments *canonicalization (on page 3418)* method is used.
- **Inclusive** - If selected, the inclusive (uncommented) *canonicalization (on page 3418)* method is used.

> **Note:**
> *Inclusive Canonicalization* copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. Inclusive *Canonicalization* is useful when it is less likely that the signed data will be inserted

in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the Inclusive *Canonicalization* will copy them and the signature will be invalid.

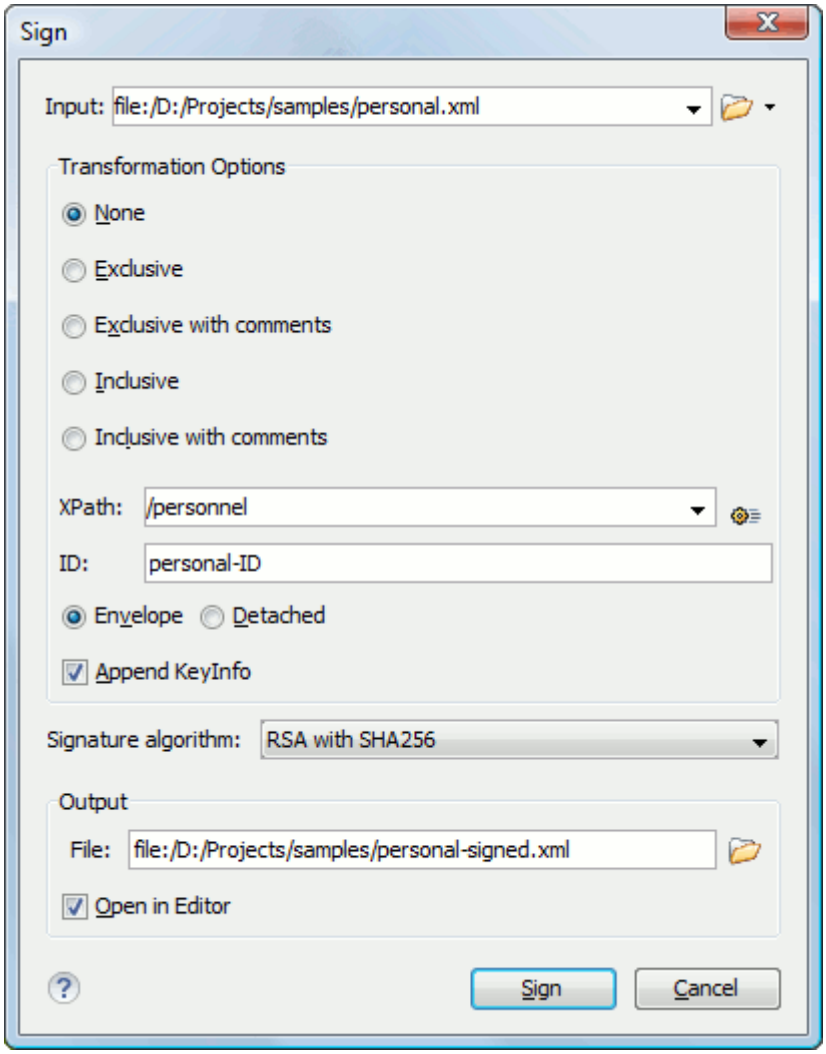
- **Inclusive with comments** - If selected, the inclusive with comments *canonicalization (on page 3418)* method is used.
- **XPath** - The XPath expression provides the fragments of the XML document to be signed.
- **Output** - Available if the **Canonicalize** action was selected from the **Tools** menu. It allows you to specify the output file path where the signed XML document will be saved.
- **Open in editor** - If selected, the output file will be opened in the editor.

Related Information:
Digital Signatures Overview *(on page 890)*

Signing Files

You can select the type of signature to be used for documents from a signature settings dialog box. To open this dialog box, select the **Sign** action from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu.

Figure 678. Signature Settings Dialog Box



The following options are available:

Note:
If Oxygen XML Editor could not find a valid certificate, a link is provided at the top of the dialog box that opens the XML Signing Certificates preferences page *(on page 276)* where you can configure a valid certificate.

- **Input** - Available if the **Sign** action was selected from the **Tools** menu. Specifies the location of the input URL.
- **Transformation Options** - See the Digital Signature Overview *(on page 890)* section for more information about these options.

- **None** - If selected, no *canonicalization (on page 3418)* algorithm is used.
- **Exclusive** - If selected, the exclusive (uncommented) *canonicalization (on page 3418)* method is used.

> **Note:**
> *Exclusive Canonicalization* just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents (or you need self-signed structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.

- **Exclusive with comments** - If selected, the exclusive with comments *canonicalization (on page 3418)* method is used.
- **Inclusive** - If selected, the inclusive (uncommented) *canonicalization (on page 3418)* method is used.

> **Note:**
> *Inclusive Canonicalization* copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. Inclusive *Canonicalization* is useful when it is less likely that the signed data will be inserted in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the Inclusive *Canonicalization* will copy them and the signature will be invalid.

- **Inclusive with comments** - If selected, the inclusive with comments *canonicalization (on page 3418)* method is used.

- **XPath** - The XPath expression provides the fragments of the XML document to be signed.
- **ID** - Provides ID of the XML element to be signed.
- **Envelope** - If selected, the *enveloped* signature is used. See the Digital Signature Overview *(on page 890)* for more information.
- **Detached** - If selected, the *detached* signature is used. See the Digital Signature Overview *(on page 890)* for more information.
- **Append KeyInfo** - If this option is selected, the `<ds:KeyInfo>` element will be added in the signed document.
- **Signature algorithm** - The algorithm used for signing the document. The following options are available: **RSA with SHA1**, **RSA with SHA256**, **RSA with SHA384**, and **RSA with SHA512**.
- **Output** - Available if the **Sign** action was selected from the **Tools** menu. Specifies the path of the output file where the signed XML document will be saved.
- **Open in editor** - If selected, the output file will be opened in Oxygen XML Editor.

Related Information:
Digital Signatures Overview *(on page 890)*
Verifying Signature *(on page 898)*
Example of How to Digitally Sign XML Files or Content *(on page 898)*

Verifying Signature

You can verify the signature of a file by selecting the **Verify Signature** action from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu. The **Verify Signature** dialog box then allows you to specify the location of the file whose signature is verified.

If the signature is valid, a dialog box displays the name of the signer. Otherwise, an error shows details about the problem.

Example of How to Digitally Sign XML Files or Content *(on page 898)*

WSDL SOAP Analyzer Tool (Deprecated)

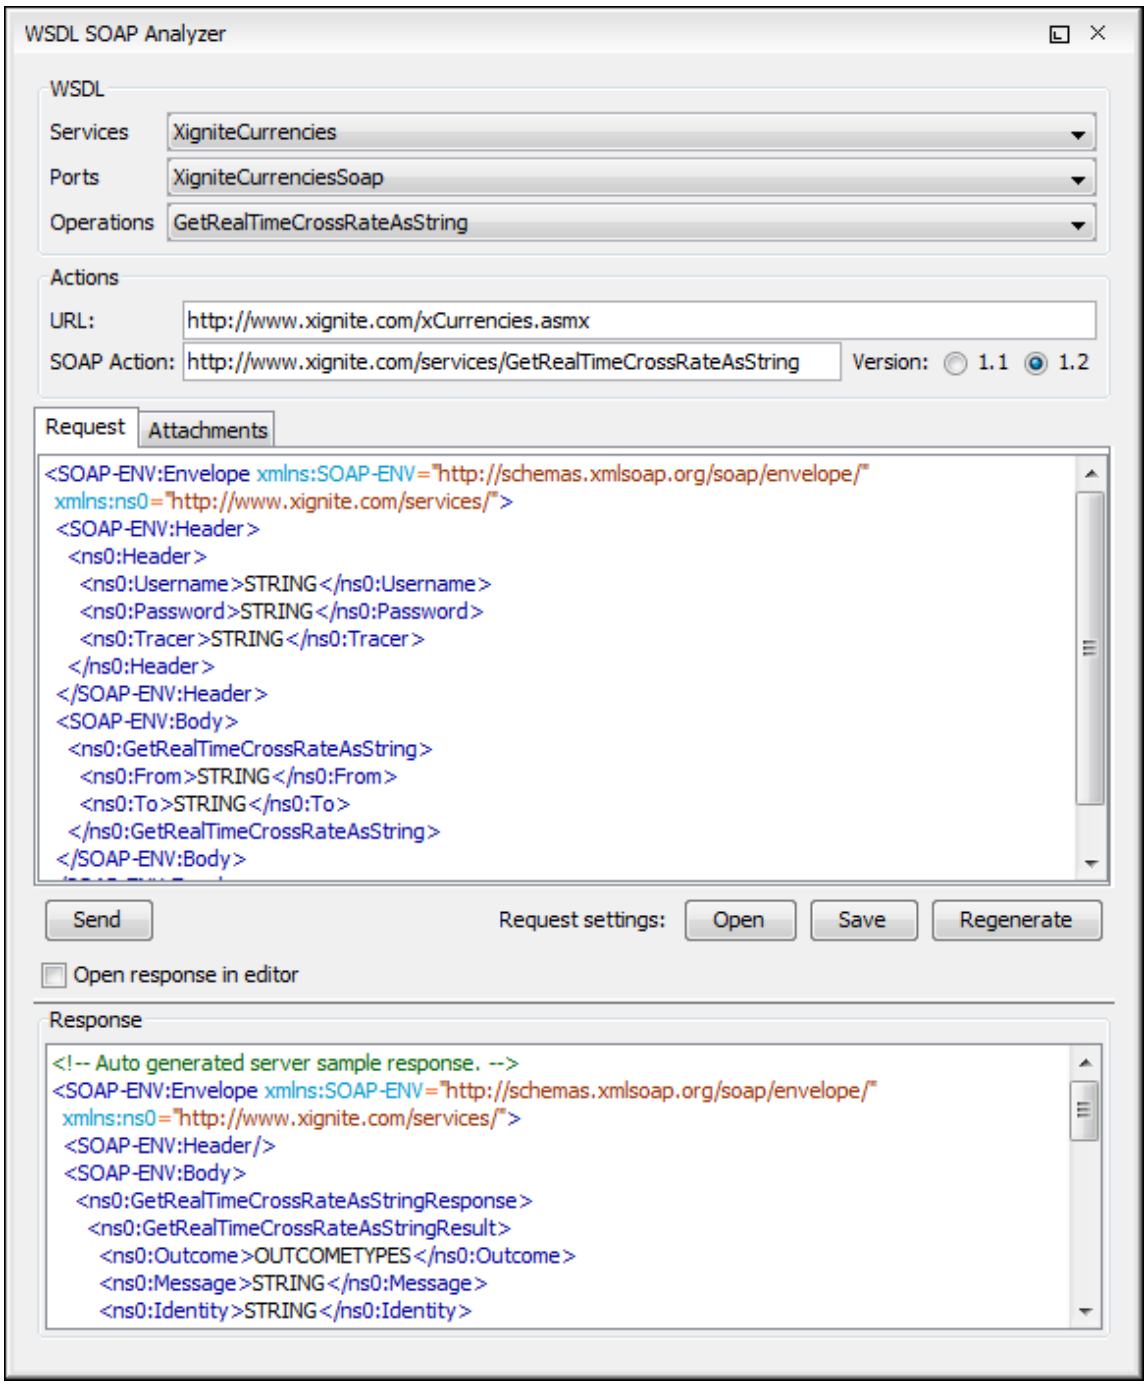
WSDL SOAP Analyzer is a tool that helps you test if the messages defined in a Web Service Descriptor (WSDL) are accepted by a Web Services server.

After you edit and validate your Web service descriptor against a mix of the XML Schemas for WSDL and SOAP, it is easy to check if the defined SOAP messages are accepted by the remote Web Services server by using the integrated **WSDL SOAP Analyzer** tool (available from the toolbar or **Tools** menu).

Oxygen XML Editor provides two ways of testing, one for the currently edited WSDL document and another for the remote WSDL documents that are published on a web server. To open the **WSDL SOAP Analyzer** tool for the currently edited WSDL document do one of the following:

- Click the **WSDL SOAP Analyzer** toolbar button.
- Use the **WSDL SOAP Analyzer** action from the **Tools** menu.
- Go to **Open with > WSDL SOAP Analyzer** in the contextual menu of the **Project** *(on page 413)* view.

Figure 679. WSDL SOAP Analyzer Dialog Box



This tool contains a SOAP analyzer and sender for Web Services Description Language file types. The analyzer fields are as follows:

- **Services** - The list of services defined by the WSDL file.
- **Ports** - The ports for the selected service.
- **Operations** - The list of available operations for the selected service.
- **Action URL** - The script that serves the operation.
- **SOAP Action** - Identifies the action performed by the script.
- **Version** - Choose between 1.1 and 1.2. The SOAP version is selected automatically depending on the selected port.

- **Request Editor** - It allows you to compose the web service request. When an action is selected, Oxygen XML Editor tries to generate as much content as possible for the SOAP request. The envelope of the SOAP request has the correct namespace for the selected SOAP version, that is *http://schemas.xmlsoap.org/soap/envelope/* for SOAP 1.1 or *http://www.w3.org/2003/05/soap-envelope* for SOAP 1.2. Usually you just have to change a few values for the request to be valid. The *Content Completion Assistant (on page 3418)* is available for this editor and is driven by the schema that defines the type of the current message. While selecting various operations, Oxygen XML Editor remembers the modified request for each one. You can click the **Regenerate** button to overwrite your modifications for the current request with the initial generated content.
- **Attachments List** - You can define a list of file URLs to be attached to the request.
- **Response Area** - Initially it displays an auto generated server sample response so you can have an idea about how the response looks like. After pressing the **Send** button, it presents the message received from the server in response to the Web Service request. It may show also error messages. If the response message contains attachments, Oxygen XML Editor prompts you to save them, then tries to open them with the associated system application.
- **Errors List** - There may be situations where the WSDL file is respecting the WSDL XML Schema, but it fails to be valid (for example, in the case of a message that is defined by means of an element that is not found in the types section of the WSDL). In such a case, the errors are listed here. This list is presented only when there are errors.
- **Send Button** - Executes the request. A status dialog box is displayed when Oxygen XML Editor is connecting to the server.

The testing of a WSDL file is straight-forward. Click the WSDL analysis button, then select the service, the port, and the operation. The editor generates the skeleton for the SOAP request. You can edit the request, eventually attach files to it and send it to the server. Watch the server response in the response area. You can find more details in the Testing Remote WSDL Files *(on page 1088)* section.

Note:
SOAP requests and responses are automatically validated in the **WSDL SOAP Analyzer** using the XML Schemas specified in the WSDL file.

Once defined, a request derived from a Web Service descriptor can be saved with the **Save** button to a Web Service SOAP Call (WSSC) file for later reuse. In this way, you save time in configuring the URLs and parameters.

You can open the result of a Web Service call in an editor panel using the **Open** button.

Testing Remote WSDL Files

To open and test a remote WSDL file the steps are the following:

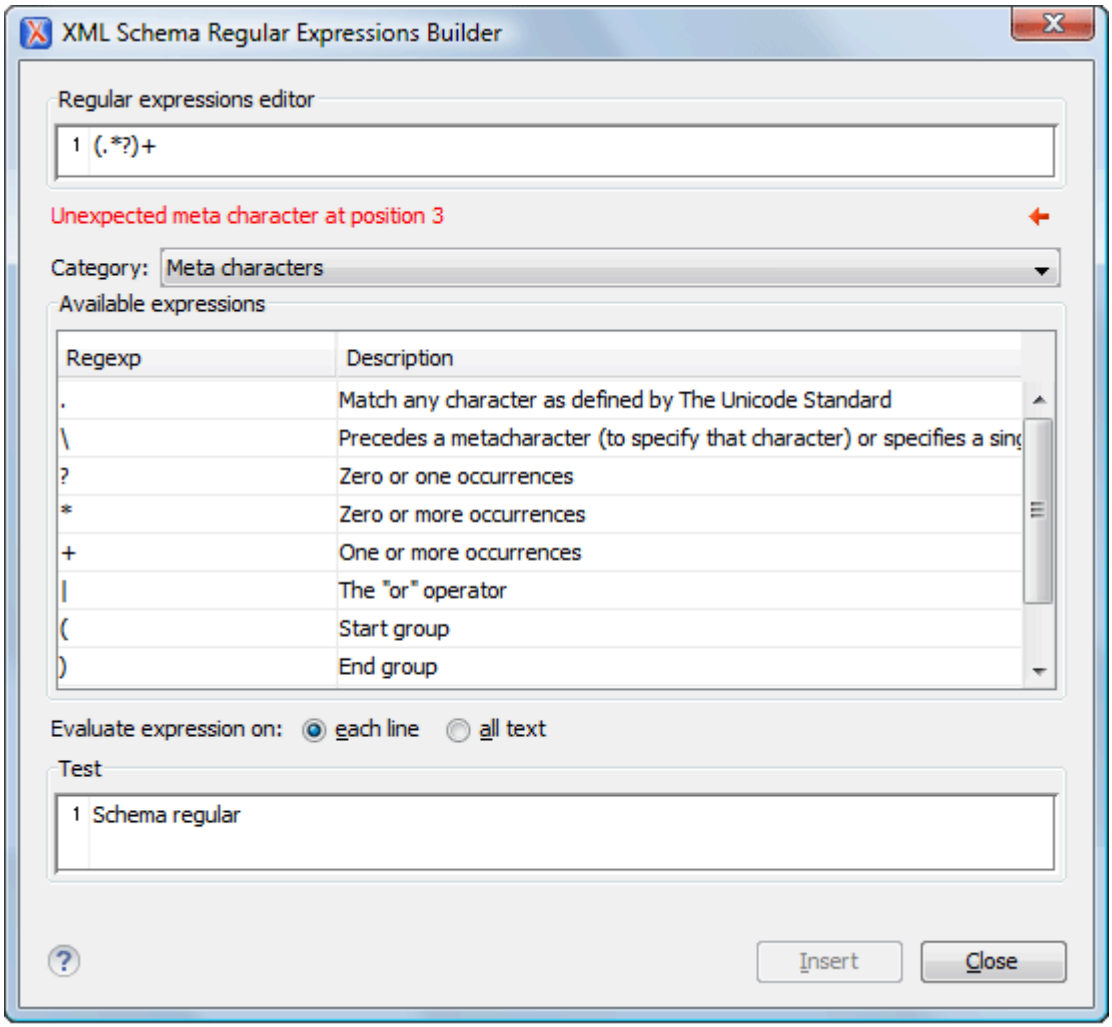
1. Go to **Tools >** **WSDL SOAP Analyzer** .
2. On the **WSDL File** tab enter the URL of the remote WSDL file.

3. Click the **OK** button.
   This will open the **WSDL SOAP Analyzer** tool *(on page 1085)*. In the **Saved SOAP Request** tab you can open directly a previously saved Web Service SOAP Call (WSSC) file, thus skipping the analysis phase.

XML Schema Regular Expressions Builder Tool

The XML Schema regular expressions builder allows you to test regular expressions on a fragment of text as they are applied to an XML instance document. Start the tool by selecting **XML Schema Regular Expressions Builder** from the **Tools** menu.

Figure 680. XML Schema Regular Expressions Builder Dialog Box



The dialog box contains the following:

Regular expressions editor

Allows you to edit the regular expression to be tested and used. Content completion is available and presents a list with all the predefined expressions. It is triggered by pressing **Ctrl + Space**.

Error display area

If the edited regular expression is incorrect, an error message will be displayed here. The message contains the description and the exact location of the error. Also, clicking the quick navigation button ( ) highlights the error inside the regular expression.

Category

You can choose from several categories of predefined expressions. The selected category influences the displayed expressions in the **Available expressions** table.

Available expressions

This table includes the available regular expressions and a short description for each of them. The set of expressions depends on the category selected in the previous **Category** combo box. You can add an expression in the **Regular expressions editor** by double-clicking the expression row in the table. You will notice that in the case of **Character categories** and **Block names**, the expressions are also listed in complementary format.

Evaluate expression on

You can choose between two options:

- **Evaluate expression on each line** - The edited expression will be applied on each line in the **Test** area.
- **Evaluate expression on all text** - The edited expression will be applied on the whole text.

Test

A text editor that allows you to enter a text sample that will have the regular expression applied. All matches of the edited regular expression will be highlighted.

After editing and testing your regular expression you can insert it in the current editor. The **Insert** button will become active when an editor is opened in the background and there is an expression in the **Regular expressions editor**.

The regular expression builder cannot be used to insert regular expressions in the **Grid** mode *(on page 363)* or schema **Design** mode *(on page 364)*. Accordingly, the **Insert** button will be not available if the current document is edited in these modes.

Note:
Some regular expressions may indefinitely block the Java Regular Expressions engine. If the execution of the regular expression does not end in about five seconds, the application displays a dialog box that allows you to interrupt the operation.

Large File Viewer

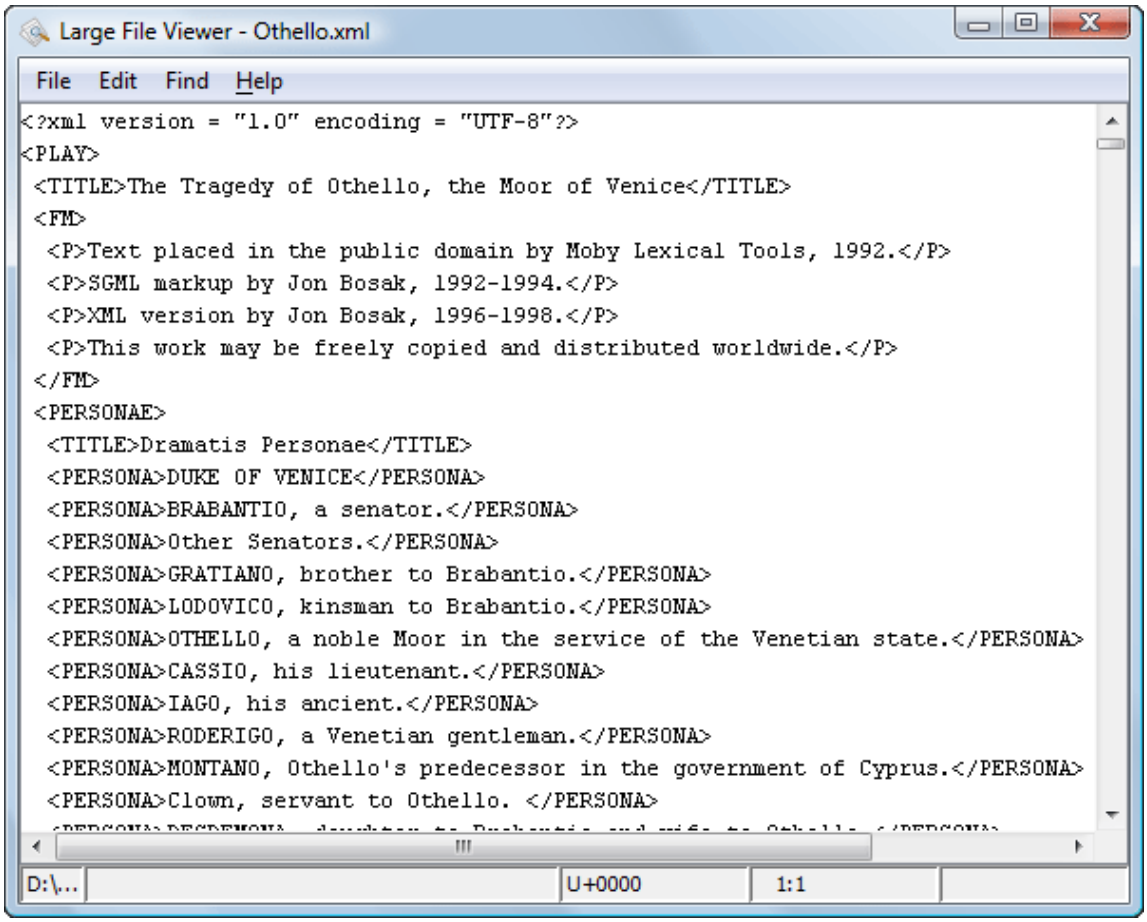
XML files tend to become larger and larger mostly because they are frequently used as a format for database export or for porting between multiple database formats. Traditional XML text editors simply cannot handle opening these huge export files, some having sizes exceeding one gigabyte, because all of the file content must be loaded in memory before the user can actually view it.

The best performance of the viewer is obtained for encodings that use a fixed number of bytes per character (such as UTF-16 or ASCII). The performance for UTF-8 is very good for documents that use mostly characters

of the European languages. For the same encoding, the rendering performance is higher for files consisting of long lines (up to few thousands characters) and may degrade for short lines. In fact, the maximum size of a file that can be rendered in the Large File Viewer decreases when the total number of the text lines of the file increases. Trying to open a very large file (for example, a file of 4 GB) with a very high number of short lines (100 or 200 characters per line) may produce an *out of memory* error (**OutOfMemoryError**) that would require either increasing the Java heap memory with the **-Xmx** startup parameter or decreasing the total number of lines in the file.

The powerful **Large File Viewer** is available from the **Tools** menu or as a standalone application. You can also right-click a file in your project and choose to open it with the viewer. It uses an efficient structure for indexing the open document. No information from the file is stored in the main memory, just a list of indexes in the file. In this way the viewer can open very large files, up to 10 gigabytes. If the open file is XML, the encoding used to display the text is detected from the XML prolog of the file. For other file types, the encoding is taken from the Oxygen XML Editor options. See Encoding for non-XML files *(on page 175)*.

Figure 681. Large File Viewer



Large File Viewer components:

- The menu bar provides menu driven access to all the features and functions that are available in **Large File Viewer**:

  File > Open

Opens files in the viewer (also available in the contextual menu).

File > Exit

Closes the viewer.

Edit > Copy

Copies the selected text to clipboard (also available in the contextual menu).

Find > Find

Opens a reduced **Find** dialog box that provides some basic search options, such as:

- **Case sensitive** - When selected, operations are case-sensitive.
- **Regular Expression** - When selected, allows you to use any regular expression in Perl-like syntax *(on page 457)*.
- **Wrap around** - Continues the find operation from the start/end of the document after reaching the end/, depending on whether the search is in forward or backward direction.

Help > Help

Provides access to the User Manual.

- The status bar provides information about the current file path, the Unicode representation of the character at the cursor position and the line and column in the open document where the cursor is located.

Attention:
For faster computation the **Large File Viewer** uses a fixed font (plain, monospace font of size 12) to display characters. The font is *not* configurable from the **Preferences** page *(on page 131)*.

Tip:
The best performance of the viewer is accomplished for encodings that use a fixed number of bytes per character (such as UTF-16 or ASCII). The performance for UTF-8 is very good for documents that use mostly characters of the European languages. For the same encoding the rendering performance is high for files consisting of short lines (up to a few thousand characters) and may degrade for long lines.

Hex Viewer

When the Unicode characters that are visible in a text viewer or editor are not enough and you need to see the byte values of each character of a document, you can start the **Hex Viewer** that is available on the **Tools** menu. It has two panels: the characters are rendered in the right panel and the bytes of each character are displayed in the left panel. There is a 1:1 correspondence between the characters and their byte representation: the byte representation of a character is displayed in the same matrix position of the left panel as the character in the matrix of the right panel.

Figure 682. Hex Viewer

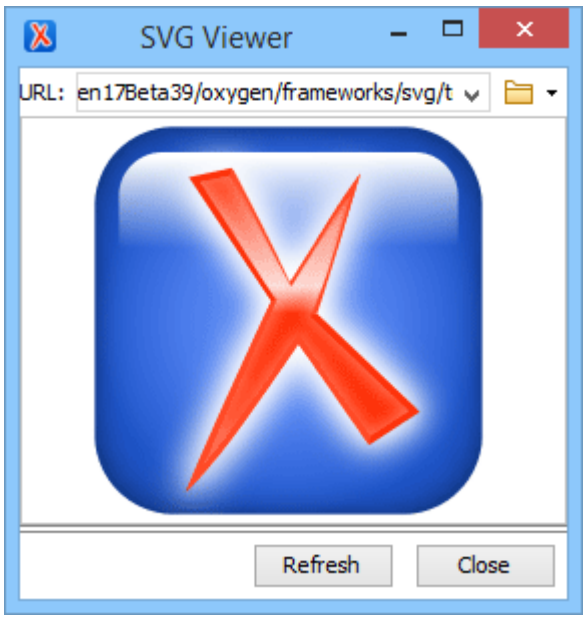
To open a file in **Hex Viewer** use the **File > Open** action. Alternatively, you can drag a file and drop it in the **Hex Viewer** panel.

Standalone SVG Viewer

Oxygen XML Editor includes a simple **SVG Viewer** that allows you to work with SVG images.

To open the viewer, select **SVG Viewer** from the **Tools** menu.

Figure 683. SVG Viewer



You can browse for and open any SVG file that has the `.svg` or `.svgz` extension.

If the file is included in the current project, you can open it in the viewer by right-clicking the image file in the **Project** view *(on page 413)* and selecting **Open with > SVG Viewer**.

Actions Available in the SVG Viewer

The following actions are available in the **SVG Viewer**:

Zoom in

To zoom in on an image, use any of the following methods:

- Scroll **forward** with the mouse wheel.
- Select **Zoom in** from the contextual menu.
- Use the **Ctrl + I (Command + I on macOS)** keyboard shortcut.

Zoom out

To zoom in on an image, use any of the following methods:

- Scroll **backward** with the mouse wheel.
- Use the **Ctrl + O (Command + O on macOS)** keyboard shortcut.
- Select **Zoom out** from the contextual menu.

Rotate

To rotate an image, use either of the following methods:

- Use the **Ctrl + Right-Click + Drag (Command + Right-Click + Drag on macOS)** shortcut.
- Select **Rotate** from the contextual menu. This rotates the image exactly 90 degrees clockwise.

Refresh

To refresh (or reset) an image, use either of the following methods:

- Use the **Ctrl + T (Command + T on macOS)** keyboard shortcut.
- Select **Refresh** from the contextual menu.

Move

To move an image, use either of the following methods:

- Use the **Arrow Keys** on your keyboard.
- Use the **Shift + Left-Click + Drag** shortcut.

Pan

To pan an image, **click and drag** the image with your mouse.

Related Information:
Editing SVG Files *(on page 1285)*

Tree Editor (Deprecated)

The **Tree Editor** (**Tools > Tree Editor**) is used for editing the content of a document displayed as an XML tree. The workspace offers the following functional areas:

- **Main menu** - Provides access to all the features and functions available in Oxygen XML Editor **Tree Editor**.
- **Toolbar** - Provides easy access to common and frequently used functions. Each icon is a button that acts as a shortcut to a related function.
- **Editor panel** - Easy editing of structured mark-up documents. Each token has an associated icon for easier visual identification.
- **Message panel** - Displays messages returned from user operations.
- **Model view** - Shows the detailed information about the attribute or element that you are working on.
- **All Elements panel** - Presents a list of all defined elements that can be inserted within your document.

The tree editor does not offer entity support. Entities are not presented with a special type of node in the tree and new entity nodes cannot be inserted in the document.

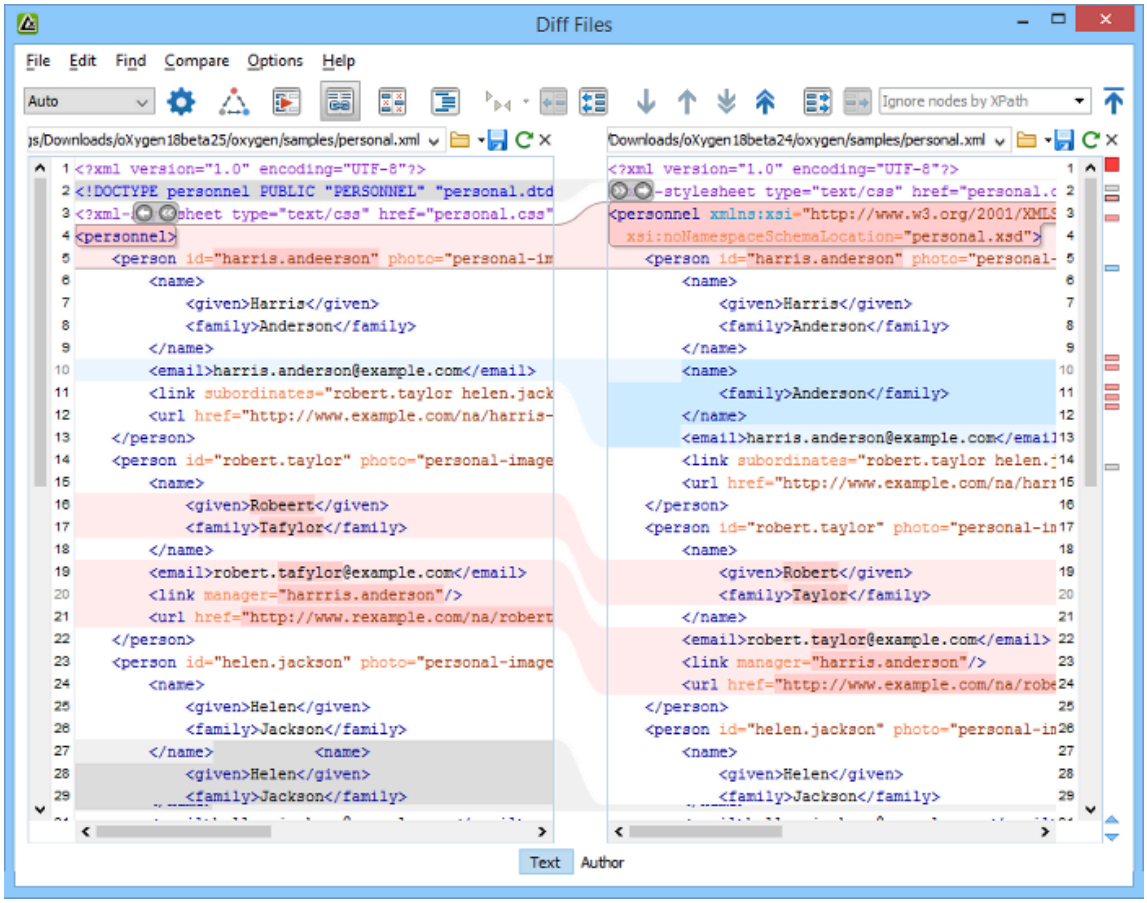
Comparison Tools

Oxygen XML Editor includes some useful tools for comparing files and directories. These tools are found in the **Comparison Tools** submenu within the **Tools** menu.

Compare Files Tool

The built-in **Compare Files** tool can be used to compare files or XML file fragments. The tool provides a mechanism for comparing two files or fragments, as well as the mechanism for a three-way comparison. The utility is available from the **Tools > Comparison Tools** menu or can be opened as a stand-alone application from the Oxygen XML Editor installation folder (`diffFiles.exe`).

Figure 684. Compare Files Tool



Two-Way Comparisons

The **Compare Files** tool can be used to compare the differences between two files or XML fragments.

Compare Files

To perform a two-way comparison, follow these steps:

1. Open a file in the left panel and the file you want to compare it to in the right panel. You can specify the path by using the text field, the history drop-down, or the browsing actions in the **Browse** drop-down menu.

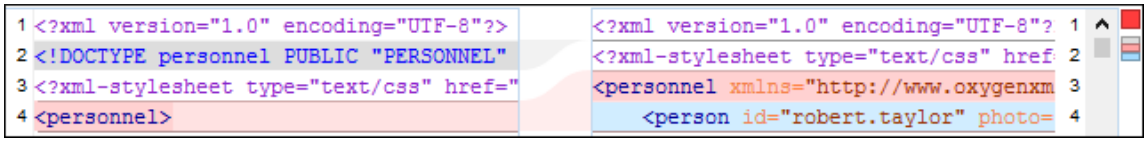
   Step Result: The selected files are opened in the two side-by-side editors. A text editing mode is used to offer a better view of the differences.

2. To highlight the differences between the two files, click the **Perform File Differencing** button from the toolbar.
3. You can use the drop-down menu on the left side of the toolbar to change the algorithm *(on page 2847)* for the operation.

4. You can also use the **Diff Options** button to access the **Files Comparison** preferences page where you can choose to ignore certain types of markup and configure various options.
5. If you are comparing XML documents using the **XML Fast** or **XML Accurate** algorithms, you can enter an XPath 2.0 expression in the **Ignore nodes by XPath** text field to ignore certain nodes from the comparison.

The resulting comparison will show you differences between the two files. The line numbers on each side and colored marks on the right-side vertical stripe help you to quickly identify the locations of the differences. Adjacent changes are grouped into blocks of changes. This layout allows you to easily identify and focus on a group of related changes.

Figure 685. Two-Way Differences



Highlighting Colors

The differences are also highlighted in several colors, depending on the type of change, and dynamic lines connect the compared fragments in the middle section between the two panes. The highlighting colors can be customized in the **Files Comparison / Appearance** preferences page *(on page 297)*, but the default colors and their shades mean the following:

- **Pink** - Identifies modifications on either side.
- **Gray** - Identifies an addition of a node in the left side (your outgoing changes).
- **Blue** - Identifies an addition of a node in the right side (incoming changes).
- **Lighter Shade** - Identifies blocks of changes that can be merged in their entirety.
- **Darker Shade** - Identifies specific changes within the blocks that can be merged more precisely.

Comparing Fragments (Copy/Paste)

To compare XML file fragments, you need to copy and paste the fragments you want to compare into each side, without selecting a file. If a file is already selected, you need to close it using the **Close (Ctrl + W (Command + W on macOS))** button, before pasting the fragments. Other notes for pasting fragments:

- As long as the fragment is more than 10 characters, the application will attempt to automatically detect the content type. It can detect the following types: XML, DTD, CSS, JSON, and Markdown (if it starts with #). If one of those content types is detected, the fragments will be displayed with syntax highlights.
- If you save modified fragments, a dialog box opens that allows you to save the changes as a new document.

Navigate Differences

To navigate through differences, do one of the following:

- Use the navigation buttons on the toolbar (or in the **Compare** menu).
- Select a block of differences by clicking its small colored marker in the overview ruler located in the right-most part of the window. At the top of the overview ruler there is a success indicator that turns green where there are no differences, or red if differences are found.
- Click a colored area in between the two text editors.

Editing Actions

You can edit the files directly in either editing pane. The two editors are constantly synchronized and the differences are refreshed when you save the modified document or when you click the **Perform File Differencing** button.

A variety of actions are available on the toolbar *(on page 496)* and in the various menus *(on page 500)* (these same actions are also available in the contextual menu in both editing panes). The tool also includes some inline actions to help you merge, copy, or remove changes. When you select a change, the following inline action widgets are available, depending on the type of change:

Append left change to right and Append right change to left

Copies the content of the selected change from one side and appends it on the other, according to the content of the corresponding change. As a result, the side where the arrow points to will contain the changes from both sides.

Copy change from left to right and Copy change from right to left

Replaces the content of a change from one side with the content of the corresponding change from the other side.

Remove change

Rejects the change on the particular side and preserves the particular content on the other side.

Two-Way Diff Algorithms

Oxygen XML Editor offers the following two-way diff algorithms to compare files or fragments:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Characters** - Computes the differences at character level, meaning that it compares two files or fragments looking for identical characters. This algorithm is not available when the file comparison is in **Author** comparison mode.
- **Words** - Computes the differences at word level, meaning that it compares two files or fragments looking for identical words. This algorithm is not available when the file comparison is in **Author** comparison mode.
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** comparison mode.

- **Syntax Aware** - Computes differences for known file types or fragments. This algorithm splits the files or fragments into sequences of *tokens* and computes the differences between them. The meaning of a *token* depends on the type of compared files or fragments.

  Known file types include those listed in the **New** dialog box, such as XML file types (XSLT files, XSL-FO files, XSD files, RNG files, NVDL files, etc.), XQuery file types (`.xquery`, `.xq`, `.xqy`, `.xqm` extensions), DTD file types (`.dtd`, `.ent`, `.mod` extensions), TEXT file type (`.txt` extension), or PHP file type (`.php` extension).

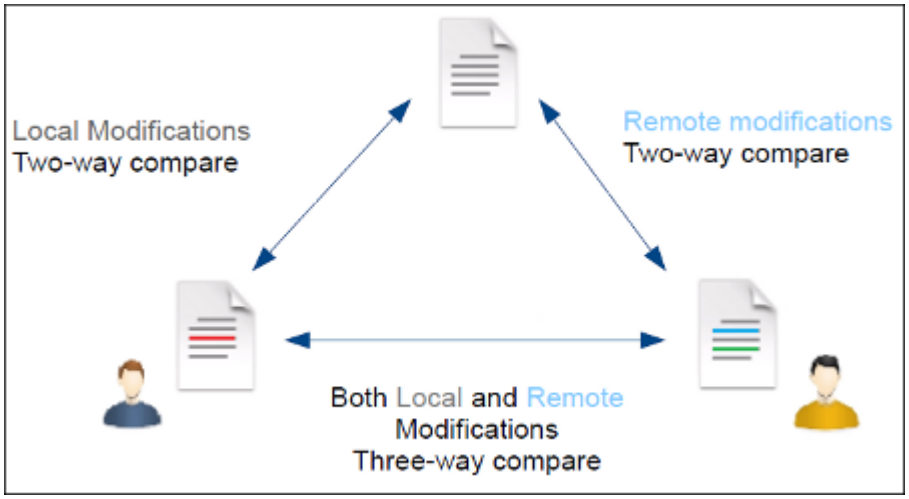
  For example:
  - When comparing XML files or fragments, a token can be one of the following:
    - The name of an XML tag
    - The **<** character
    - The **/>** sequence of characters
    - The name of an attribute inside an XML tag
    - The **=** sign
    - The **"** character
    - An attribute value
    - The text string between the start tag and the end tag (a text node that is a child of the XML element corresponding to the XML tag that encloses the text string)
  - When comparing plain text, a token can be any continuous sequence of characters or any continuous sequence of whitespaces, including a new line character.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Three-Way Comparisons

Oxygen XML Editor also includes a three-way comparison feature to help you solve conflicts and merge changes between multiple modifications. It is especially helpful for teams who have multiple authors editing and committing the same documents. It provides a comparison between a local change, another change, and the original base revision. Some additional advantages include:

- Visualize and merge content that was modified by you and another member of your team.
- Marks differences correctly even when the document structure is rearranged.
- Allows you to merge XML-relevant modifications.

Figure 686. Three-Way Comparison



Compare Files

To perform a three-way comparison, follow these steps:

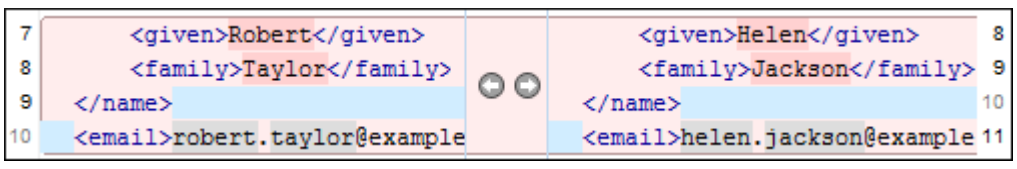
1. Open a file in the left panel and the file you want to compare it to in the right panel. You can specify the path by using the text field, the history drop-down, or the browsing actions in the **Browse** drop-down menu.

   Step Result: The selected files are opened in the two side-by-side editors. A text editing mode is used to offer a better view of the differences.

2. Click the **Three-Way Comparison** button on the toolbar and select the base (original) file in the **Base** field. You can specify the path by using the text field, the history drop-down, or the browsing actions in the **Browse** drop-down menu.
3. To highlight the differences, click the **Perform File Differencing** button on the toolbar.
4. You can use the drop-down menu on the left side of the toolbar to change the algorithm *(on page 2847)* for the operation.
5. You can also use the **Diff Options** button to access the **Files Comparison** preferences page where you can choose to ignore certain types of markup and configure various options.

The resulting comparison will show you differences between the two files, as well as differences between either of them and the base (original) file. The line numbers on each side and colored marks on the right-side vertical stripe help you to quickly identify the locations of the differences. Adjacent changes are grouped into blocks of changes.

Figure 687. Three-Way Differences



Highlighting Colors

The differences are also highlighted in several colors, depending on the type of change, and dynamic lines connect the compared fragments in the middle section between the two panes. The highlighting colors can be customized in the **Files Comparison / Appearance** preferences page *(on page 297)*, but the default colors and their shades mean the following:

- **Pink** - Identifies blocks of changes that include conflicts.
- **Gray** - Identifies your outgoing changes that do not include conflicts.
- **Blue** - Identifies incoming changes that do not include conflicts.
- **Lighter Shade** - Identifies blocks of changes that can be merged in their entirety.
- **Darker Shade** - Identifies specific changes within the blocks that can be merged more precisely.

Navigate Differences

To navigate through differences, do one of the following:

- Use the navigation buttons on the toolbar (or in the **Compare** menu).
- Select a block of differences by clicking its small colored marker in the overview ruler located in the right-most part of the window. At the top of the overview ruler there is a success indicator that turns green where there are no differences, or red if differences are found.
- Click a colored area in between the two text editors.

Editing Actions

You can edit the files directly in either editing pane. The two editors are constantly synchronized and the differences are refreshed when you save the modified document or when you click the  **Perform File Differencing** button.

A variety of actions are available on the toolbar *(on page 496)* and in the various menus *(on page 500)* (these same actions are also available in the contextual menu in both editing panes). The tool also includes some inline actions to help you merge, copy, or remove changes. When you select a change, the following inline action widgets are available, depending on the type of change:

Append left change to right and Append right change to left

Copies the content of the selected change from one side and appends it on the other, according to the content of the corresponding change. As a result, the side where the arrow points to will contain the changes from both sides.

Copy change from left to right and Copy change from right to left

Replaces the content of a change from one side with the content of the corresponding change from the other side.

Remove change

Rejects the change on the particular side and preserves the particular content on the other side.

Three-Way Diff Algorithms

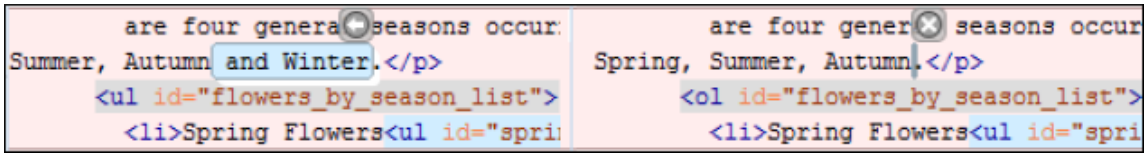
Oxygen XML Editor offers the following three-way diff algorithms to compare files:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** comparison mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Second-Level Comparisons

For both two-way and three-way comparisons, Oxygen XML Editor automatically performs a second-level comparison for the **Lines**, **XML Fast**, and **XML Accurate** algorithms. After the first comparison is finished, the second-level comparison for the **Lines** algorithm is processed on text nodes using a word level comparison, meaning that it looks for identical words. For the **XML Fast** and **XML Accurate** algorithms, the second-level comparison is processed using a syntax-aware comparison *(on page 2848)*, meaning that it looks for identical *tokens*. This second-level comparison makes it easier to spot precise differences and you can merge or reject the precise modifications.

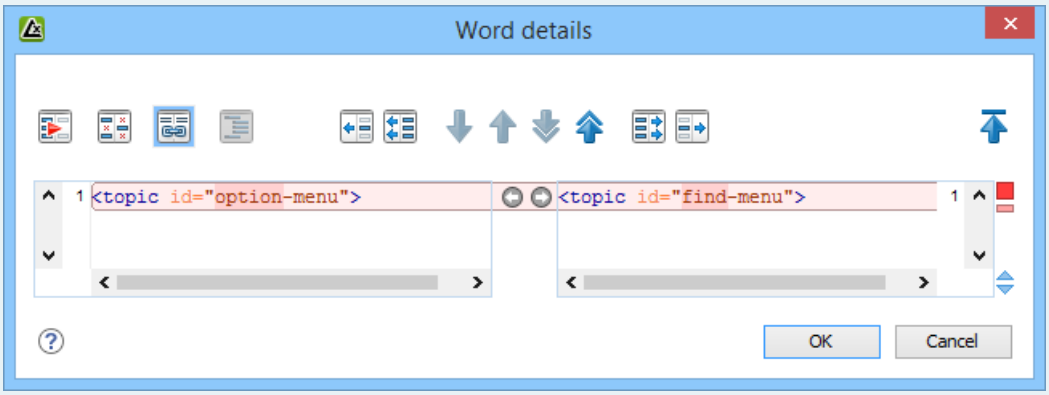
Figure 688. Second-Level Diff Comparison



Note:
If a modified text fragment contains XML markup (such as processing instructions, XML comments, CData, or elements), the second-level comparison will not automatically be performed. In this case you can manually select a second-level comparison by doing a word level or character level comparison.

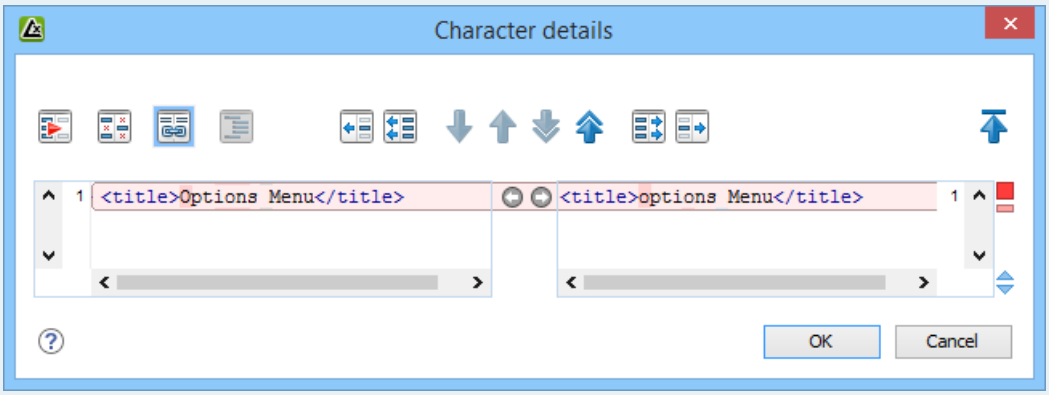
To do a word level comparison, select **Show word level details** from the contextual menu or **Compare** menu.

Figure 689. Word Level Comparison



To do a character level comparison, select **Show Character Level details** from the contextual menu or **Compare** menu.

Figure 690. Character Level Comparison



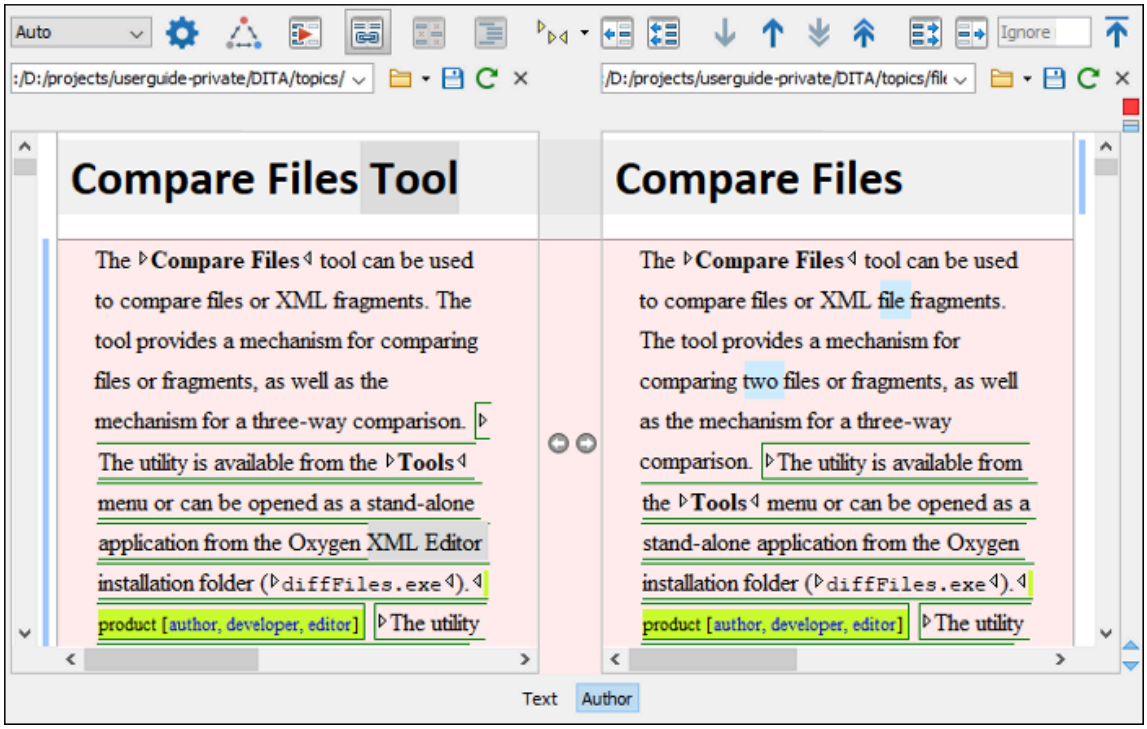
Author Visual Mode

The **Compare Files** tool includes an **Author** comparison mode that displays the files in a visual mode similar to the **Author** editing mode in *Oxygen XML Editor/Author*. This makes it easier to see how the compared changes will look in the final output. This visual mode is available when the compared files are detected as being XML. To determine whether the files are initially opened in the merge tool's **Text** or **Author** comparison mode, it detects the **Initial Edit Mode** in the *Document Type Association* configuration *(on page 149)* and the mode the files were last opened in *Oxygen XML Editor/Author*.

Note:
This mode is not available if the **Enable file comparison in Author mode** option *(on page 295)* is not selected in the **Diff > Files Comparison** preferences page.

This visual mode includes unique features such as a **Tags Display Mode** drop-down button *(on page 498)* on the toolbar that allows you to select the amount of tags to display in this visual mode. This mode also presents differences that were made using the **Track Changes** feature (although the **Track Changes** feature is not available in the comparison tool).

Figure 691. File Comparison Tool - Author Mode



Author Mode Algorithms

The visual **Author** comparison mode offers the following diff algorithms to compare files:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Author Mode Second-Level Comparisons

The visual **Author** comparison mode automatically performs a second-level comparison for the **XML Fast** and **XML Accurate** algorithms. After the first comparison is finished, the second-level comparisons is processed on text nodes using a word-level comparison, meaning that it looks for identical words. This second-level comparison makes it easier to spot precise differences and you can merge or reject the precise modifications.

Files Comparison Preferences Page *(on page 295)*
Compare Directories Tool *(on page 504)*

Starting File Comparison Tool from a Command Line

The file comparison tool can be started by using command-line arguments. In the installation folder there is an executable shell (`diffFiles.bat` on Windows, `diffFiles.sh` on macOS and Linux). To specify the files to

compare, you can pass command-line arguments using the following construct: `diffFiles.bat/diffFiles.sh [path to left file] [path to right file] [path to 3-way base file]`.

If three files are specified, the tool will start in the 3-way comparison mode *(on page 487)*. If only two files are specified, the tool will start in the 2-way comparison mode *(on page 484)*. The first specified file will be added to the left panel in the comparison tool, the second file to the right panel, and the optional third file will be the base (ancestor) file used for a 3-way comparison. If you pass only one argument, you are prompted to manually choose another file.

If you want to launch the file comparison tool from an external application with specified files and you want the file browsing buttons at the top of both panels to be hidden, you should use the `-ext` argument as the first command. There are some additional arguments that are allowed and to see all the details for the command-line construct, type `diffFiles.bat --help` in the command line.

Example:

To do a 3-way comparison, the command line might look like this:

Windows

```
diffFiles.bat "c:\docs\file 1" "c:\docs\file 2" c:\docs\basefile
```

> **Tip:**
> If there are spaces in the path names, surround the paths with quotes.

Linux

```
diffFiles.sh home/file1 home/file2 home/basefile
```

macOS

```
diffFiles.sh documents/file1 documents/file2 documents/basefile
```

How to Integrate the File Comparison Tool with Git

The file comparison tool can be integrated with Git clients. It requires that you configure your `.gitconfig` file and then you can simply start the tool from the command line.

To integrate the **Compare Files** tool with your Git client, follow this procedure:

1. Use one of the following methods to instruct your Git client to use the *Oxygen* **Compare Files** tool:
   - **Manual Configuration** - Locate your Git user-specific configuration file (`.gitconfig`) and edit it with a text editor (for example, in Windows, the `.gitconfig` file is most likely located in your user home directory). Add (or replace) the following lines:

```
[diff]
    tool = oxygendiff
[merge]
    tool = oxygendiff
```

```
[difftool "oxygendiff"]
    cmd = '[pathToOxygenInstallDir]/diffFiles.exe' -ext $REMOTE $LOCAL $LOCAL
[mergetool "oxygendiff"]
    cmd = '[pathToOxygenInstallDir]/diffFiles.exe' -ext $LOCAL $REMOTE $BASE $MERGED
    trustExitCode = true
[difftool]
    prompt = false
```

Note:
For macOS, the **cmd** lines would start with something like: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**. For Linux, the **cmd** lines would start with something like: **sh "/Oxygen XML Editor/diffFiles.sh"**.

Tip:
On Redhat 7, the following command would work, where the whole command is quoted and then inside that, the path to `diffFiles.sh` is quoted:

```
[difftool "oxygendiff"]
   cmd = '"/home/user/Oxygen XML Editor 21/diffFiles.sh"' -ext $REMOTE $LOCAL
 $LOCAL
[mergetool "oxygendiff"]
   cmd = '"/home/user/Oxygen XML Editor 21/diffFiles.sh"' -ext $LOCAL $REMOTE
 $BASE
        $MERGED trustExitCode = true
```

- **Command Line Configuration** - To automatically configure the `.gitconfig` file, you can run the following commands from a command line:

```
git config --global diff.tool oxygendiff
git config --global difftool.oxygendiff.cmd '[Oxygen install dir]/diffFiles.exe -ext
$REMOTE $LOCAL $LOCAL'
git config --global merge.tool oxygendiff
git config --global mergetool.oxygendiff.cmd '[Oxygen install dir]/diffFiles.exe
-ext $LOCAL $REMOTE $BASE $MERGED'
git config --global mergetool.oxygendiff.trustExitCode true
```

Note:
For macOS, the *Oxygen* file comparison tool would be specified in the second and fourth commands with something like: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**. For Linux, it would be something like: **sh "/Oxygen XML Editor/diffFiles.sh"**.

2. To start the **Compare Files** tool and see a comparison of changes for a particular file, run the following command from a command line:

```
git difftool [PathToFile]
```

> **Tip:**
> If the file you want to compare has conflicts, you can start the **Compare Files** tool as a *merge conflict resolution* tool by running the following command:
>
> ```
> git mergetool [PathToFile]
> ```

For more information about the Git *difftool* syntax, see https://git-scm.com/docs/git-difftool.

For more information about the Git *mergetool* syntax, see https://git-scm.com/docs/git-mergetool.

How to Integrate the File Comparison Tool with Sourcetree

The file comparison tool can be integrated with Sourcetree so that you can use it to compare changes. The advantages of doing this include:

- The *Oxygen* **Compare Files** tool presents the files side-by-side and makes it much easier to determine real changes.
- The *Oxygen* **Compare Files** tool includes XML comparison algorithms.
- The *Oxygen* **Compare Files** tool includes various options for configuring the comparison.
- The *Oxygen* **Compare Files** tool allows you to navigate through changes.

To integrate the **Compare Files** tool with Sourcetree, follow this procedure, depending on your operating system:

Windows

1. In Sourcetree, go to **Tools > Options**.
2. Go to the **Diff** tab.
3. In the **External Diff/Merge** section, configure the settings as follows:
   - **External Diff Tool** - Select **Custom**.
   - **Diff Command** - Enter the path of the *Oxygen* `diffFiles.exe` file (for example: `c:\Programs\Oxygen XML Editor\diffFiles.exe`).
   - **Arguments** - Enter **-ext $REMOTE $LOCAL $LOCAL**.
   - **Merge Tool** - Select **Custom**.
   - **Diff Command** - Enter the path of the *Oxygen* `diffFiles.exe` file (for example: `c:\Programs\Oxygen XML Editor\diffFiles.exe`).
   - **Arguments** - Enter **-ext $LOCAL $REMOTE $BASE $MERGED**.
4. Click **OK**.

Result: In Sourcetree, you can now compare file changes with the *Oxygen* **Compare Files** tool by simply selecting **External Diff** from the contextual menu, **Actions** menu, or **Ctrl+D**.

macOS

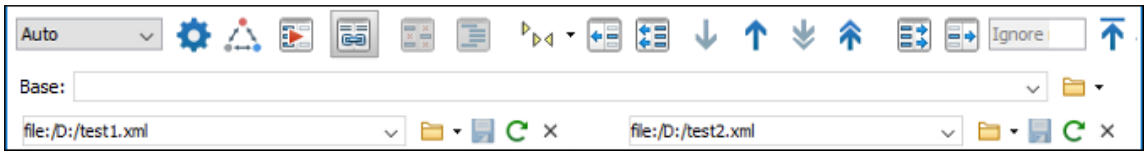
1. In Sourcetree, go to **Sourcetree > Preferences**.
2. Go to the **Diff** tab.
3. In the **External Diff/Merge** section, configure the settings as follows:
   - **External Diff Tool** - Select **Custom**.
   - **Diff Command** - Enter a command-line argument to launch the *Oxygen* `diffFiles.sh` file (for example: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**).
   - **Arguments** - Enter **-ext $REMOTE $LOCAL $LOCAL**.
   - **Merge Tool** - Select **Custom**.
   - **Diff Command** - Enter a command-line argument to launch the *Oxygen* `diffFiles.sh` file (for example: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**).
   - **Arguments** - Enter **-ext $LOCAL $REMOTE $BASE $MERGED**.
4. Close the preferences dialog box.

Result: In Sourcetree, you can now compare file changes with the *Oxygen* **Compare Files** tool by simply selecting **External Diff** from the contextual menu or **Actions** menu.

Toolbar and Contextual Menu Actions of the Compare Files Tool

The toolbar of the **Compare Files** tool contains operations that can be performed on the source and target files or XML fragments. Many of the actions are also available in the contextual menu.

Figure 692. Compare Toolbar



The following actions are available:

Algorithm

This drop-down menu allows you to select one of the following diff algorithms (depending on whether it is a two-way or three-way comparison):

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Characters** - Computes the differences at character level, meaning that it compares two files or fragments looking for identical characters. This algorithm is not available when the file comparison is in **Author** comparison mode.

- **Words** - Computes the differences at word level, meaning that it compares two files or fragments looking for identical words. This algorithm is not available when the file comparison is in **Author** comparison mode.
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** comparison mode.
- **Syntax Aware** - Computes differences for the file types or fragments known by Oxygen XML Editor, taking the syntax (the specific types of tokens) into consideration. This algorithm is not available when the file comparison is in **Author** comparison mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

 **Diff Options**

Opens the **Files Comparison** preferences page *(on page 295)* where you can configure various options.

 **Three-Way Comparison**

Toggle action that allows you to perform a three-way comparison between the two files displayed in the two editing panes and a base (ancestor) file.

 **Perform Files Differencing**

Looks for differences between the two files displayed in the left and right side panels.

 **Synchronized scrolling**

Toggles synchronized scrolling on or off so that a selected difference can be seen on both sides of the application window. This option is on by default.

 **Ignore Whitespaces**

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces. This option is not available when in the **Author** comparison mode.

 **Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on macOS))**

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences. This option is not available when in the **Author** comparison mode.

Note:
When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Tags Display Mode

Allows you to select the amount of markup to be displayed in the **Author** visual comparison mode *(on page 491)*. You can choose between: **Full Tags with Attributes**, **Full Tags**, **Block Tags**, **Block Tags without Element Names**, **Inline Tags**, **Partial Tags**, or **No Tags**.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Next Block of Changes (Ctrl + Period (Command + Period on macOS))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

> **Note:**
> A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on macOS))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on macOS))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on macOS))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Copy All Changes from Left to Right

Copies all changes from the file in the left panel to the file in the right panel.

Copy Change from Left to Right

Copies the selected difference from the file in the left panel to the file in the right panel.

Ignore Nodes by XPath

You can use this text field to enter an XPath expression *(on page 2117)* to ignore certain nodes from the comparison. It will be processed as XPath version 2.0. You can also enter the name

of the node to ignore all nodes with the specified name (for example, if you want to ignore all ID attributes from the document, you could simply enter `@id`). This field is only available when comparing XML documents using the **XML Fast** or **XML Accurate** algorithms.

> **Note:**
> If an XPath expression is specified in the **Ignore nodes by XPath** option *(on page 297)* in the **Diff / File Comparison** preferences page, that one is used as a default when the application is started. If you then enter an expression in this field on the toolbar, this one will be used instead of the default. If you delete the expression from this field, neither will be used.

First Change (Ctrl + B (Command + B on macOS))

Jumps to the first change.

Base

Available for three-way comparisons *(on page 487)*. It is the base file that will be compared with the files opened in the left and right editors. You can specify the path to the file by using the text field, its history drop-down, or the browsing actions in the **Browse** drop-down menu.

Left-Side (Source) File

You can specify the path to the file to be compared on the left side (source) by using the text field, its history drop-down, or the browsing actions in the **Browse** drop-down menu.

Save

Saves the changes made in the source (left-side) file.

Reload

Reloads the source (left-side) file.

Close

Closes the source (left-side) file.

Right-Side (Target) File

You can specify the path to the file to be compared on the right side (target) by using the text field, its history drop-down, or the browsing actions in the **Browse** drop-down menu.

Save

Saves the target (right-side) file.

Reload

Reloads the target (right-side) file.

Close

Closes the target (right-side) file.

Compare Files Tool Menus

The menus in the **Compare Files** tool contain some of the same actions that are on the toolbar, as well as some common actions that are identical to the same actions in the Oxygen XML Editor menus. The menu actions include:

File Menu

Source > Open

Browses for a file that will be displayed in the left panel.

Source > Open URL

Browses for a remote file that will be displayed in the left panel.

Source > Open File from Archive

Browses an archive for a file that will be displayed in the left panel.

Source > Reload

Reloads the file in the left panel.

Source > Save

Saves the changes made to the file in the left panel.

Source > Save As

Allows you to choose a destination to save the file in the left panel.

Source > Close

Closes the file in the left panel.

Target > Open

Browses for a file that will be displayed in the right panel.

Target > Open URL

Browses for a remote file that will be displayed in the right panel.

Target > Open File from Archive

Browses an archive for a file that will be displayed in the right panel.

Target > Reload

Reloads the file in the right panel.

Target > Save

Saves the changes made to the file in the right panel.

Target > Save As

Allows you to choose a destination to save the file in the right panel.

Target > Close

Closes the file in the right panel.

Base > Open

Browses for a file that will be compared with both files in a three-way comparison *(on page 487)*.

Base > Open URL

Browses for a remote file that will be compared with both files in a three-way comparison *(on page 487)*.

Base > Open File from Archive

Browses an archive for a file that will be compared with both files in a three-way comparison *(on page 487)*.

Save Results as HTML (Available in Text mode only)

Generates an HTML file that contains detailed information about the comparison result. See an example of what the generated report look like in the Generate HTML Report for Directory Comparison topic *(on page 521)*.

Save Comparison as Document with Tracked Changes (Available for two-way comparison in Author mode only)

Allows you to merge two compared documents based on the differences detected and save the results as a specified file that includes the special change tracking marks. You can load the resulting file in **Oxygen's Author** mode to review the changes that resulted from the merge process and you can accept or reject them. Note that if the documents to be compared already contain tracked changes, they will be automatically accepted before generating the output file.

Close (Ctrl + W (Command + W on macOS))

Closes the application.

Edit Menu

Cut

Cut the selection from the currently focused editor panel to the clipboard.

Copy

Copy the selection from the currently focused editor panel to the clipboard.

Paste

Paste content from the clipboard into the currently focused editor panel.

Select all

Selects all content in the currently focused editor panel.

Undo

Undo changes in the currently focused editor panel.

Redo

Redo changes in the currently focused editor panel.

Find Menu

Find/Replace

Perform *find/replace* operations in the currently focused editor panel.

Find Next

Go to the next match using the same options as the last *find* operation. This action runs in both editor panels.

Find Previous

Go to the previous match using the same options as the last *find* operation. This action runs in both editor panels.

Compare Menu

Three-Way Comparison

Toggle action that allows you to perform a three-way comparison between the two files displayed in the two editing panes and a base (ancestor) file.

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Next Block of Changes (Ctrl + Period (Command + Period on macOS))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

> **Note:**
> A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on macOS))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on macOS))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on macOS))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Last Change (Ctrl + E (Command + E on macOS))

Jumps to the last change.

First Change (Ctrl + B (Command + B on macOS))

Jumps to the first change.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Copy All Changes from Left to Right

Copies all changes from the file in the left panel to the file in the right panel.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy Change from Left to Right

Copies the selected difference from the file in the left panel to the file in the right panel.

Show Word Level Details

Provides a word-level comparison of the selected change.

Show Character Level Details

Provides a character-level comparison of the selected change.

Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on macOS))

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences.

> **Note:**
> When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Options Menu

Preferences

Opens the preferences dialog box that includes numerous pages of options that can be configured.

Menu Shortcut Keys

Opens the **Menu Shortcut Keys** option page where you can configure keyboard shortcuts available for menu items.

Reset Global Options

Resets options to their default values. Note that this option appears only when the tool is executed as a stand-alone application.

Import Global Options

Allows you to import an options set that you have previously exported.

Export Global Options

Allows you to export the current options set to a file.

Help Menu

Help (F1)

Opens a **Help** dialog box that displays the User Manual at a section that is appropriate for the context of the current cursor position.

Use Online Help

If this option is selected, when you select Help or press F1 while hovering over any part of the interface, Oxygen XML Editor attempts to open the help documentation in online mode. If this option is not selected or an internet connection fails, the help documentation is opened in offline mode.

Report problem

Opens a dialog box that allows the user to write the description of a problem that was encountered while using the application. You can change the URL where the reported problem is sent by using the `com.oxygenxml.report.problems.url` system property. The report is sent in XML format through the `report` parameter of the POST HTTP method.

Support Center

Opens the Oxygen XML Editor Support Center web page in a browser.

How to Compare and Merge Documents with Change Tracking Highlights

Oxygen XML Editor includes two actions (**Merge Documents with Change Tracking Highlights** and a **Merge Directories with Change Tracking Highlights**) within the **Tools > Comparison Tools** menu that can be used to compare and merge content and the comparison results are saved as documents with highlighted tracked changes that can be later reviewed and accepted or rejected.

This topic provides instructions and several different use cases for how to get the most out of comparing and merging documents with change tracking highlights present.

Use Case 1: Review Changes Made to an XML Document

The **Merge Documents with Change Tracking Highlights** tool *(on page 2872)* can be used to merge two XML documents, based on a 2-way mode comparison. The files involved in the process are merged by saving the comparison results as documents with highlighted tracked changes.

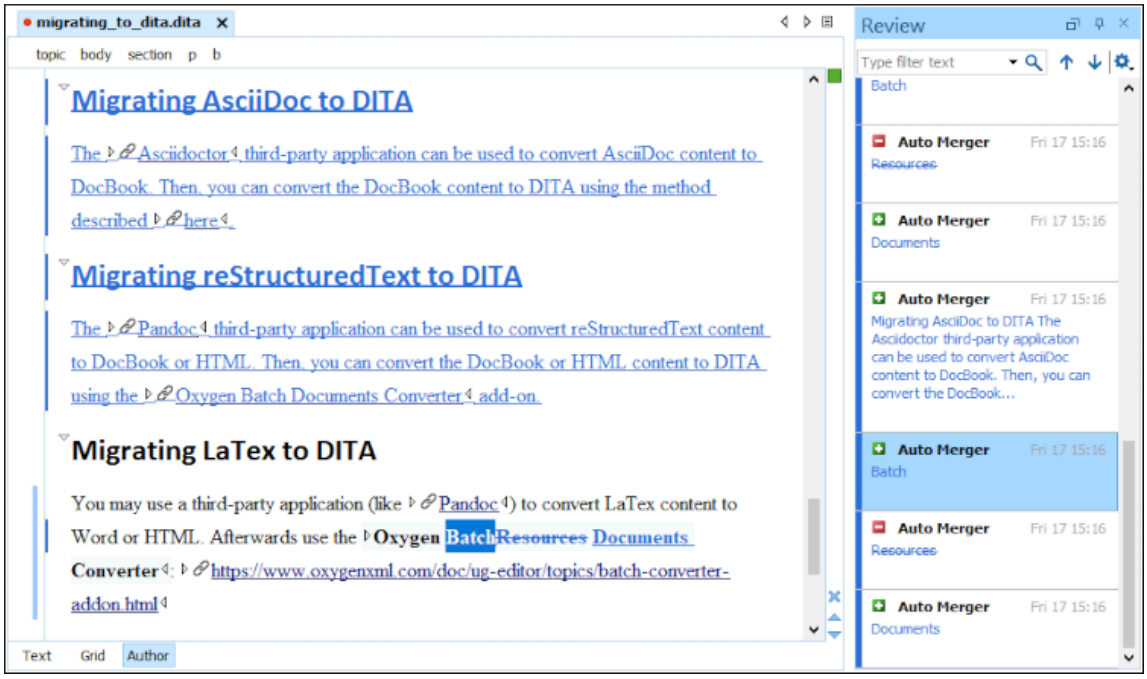
Here is the basic procedure:

1. Select the **Merge Documents with Change Tracking Highlights** action that is found in the **Tools > Comparison Tools** menu to invoke the tool. It opens a dialog box where you can specify the documents to merge.
2. In the resulting dialog box, you need to provide the URLs of the base version of the document (**Base document**) and the modified version (**Document to merge with**), and then click the **Merge** button.

   Step Result: The resulting document is automatically loaded into a new editor tab. It incorporates special markings for the tracked changes/differences between the 2 compared and analyzed XML files.
3. Switch to the **Author** mode and then open the **Review** view (click the  **Manage reviews** button on the toolbar or select it from the **Window > Show View** menu).

   Step Result: All detected changes are listed in the **Review** view and they are marked accordingly in the resulting document as well.
4. You can analyze each detected change one by one and accept or reject them individually or in bulk.
5. Save the changes you made during the reviewing process.

Figure 693. Revised Merged Document

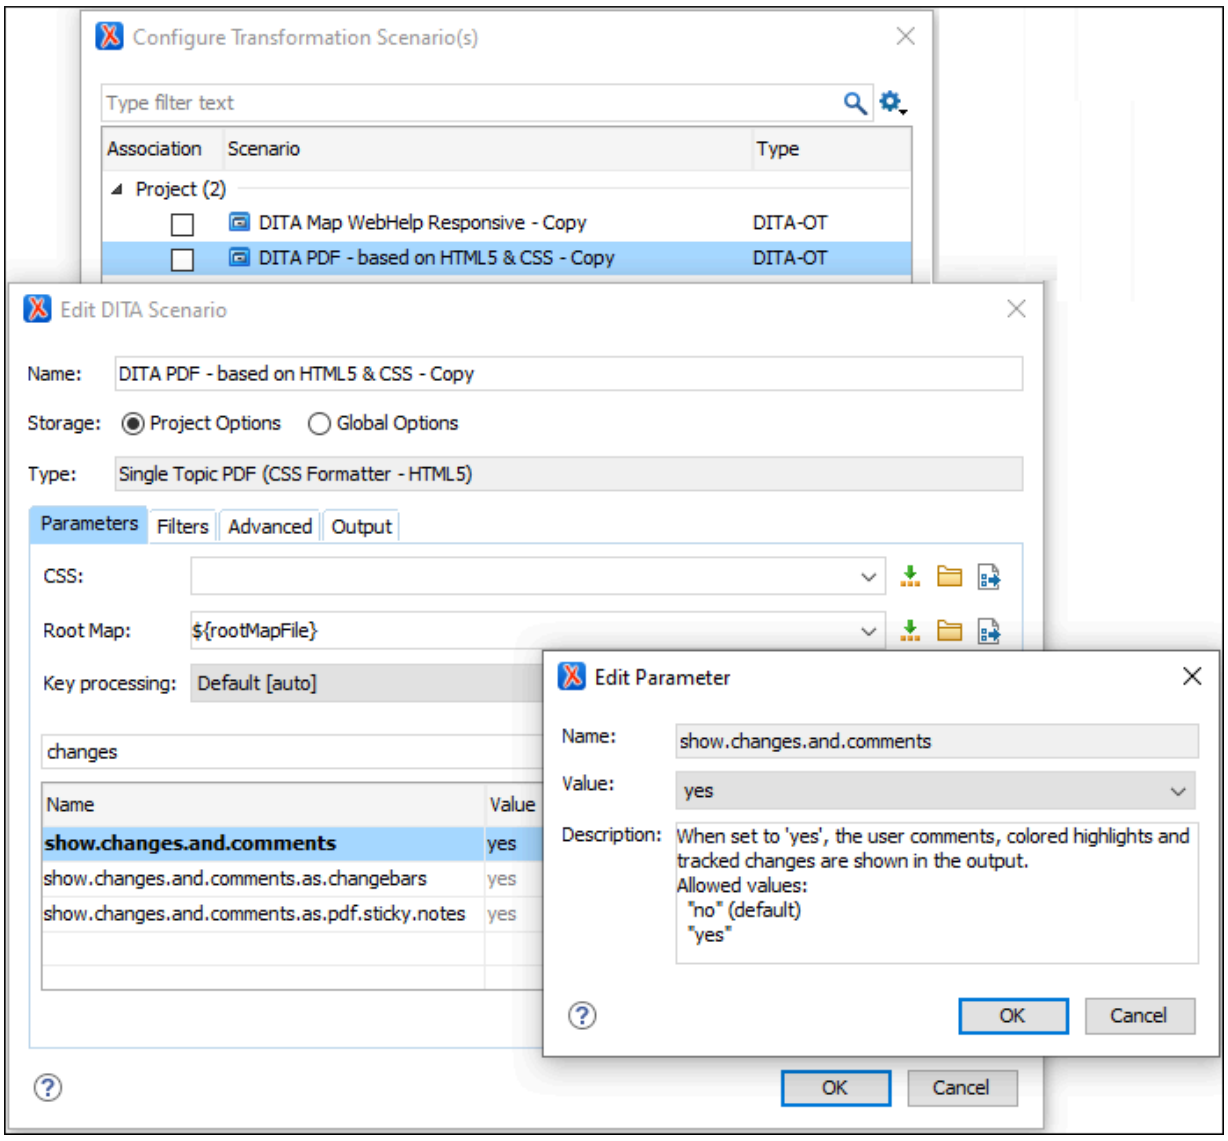


Use Case 2: Compare Differences Between Two Versions

Another interesting way of using the resulting merged document that incorporates the change tracking marks between 2 versions is to apply a transformation of the resulting document into a PDF file that highlights the changes between the compared versions.

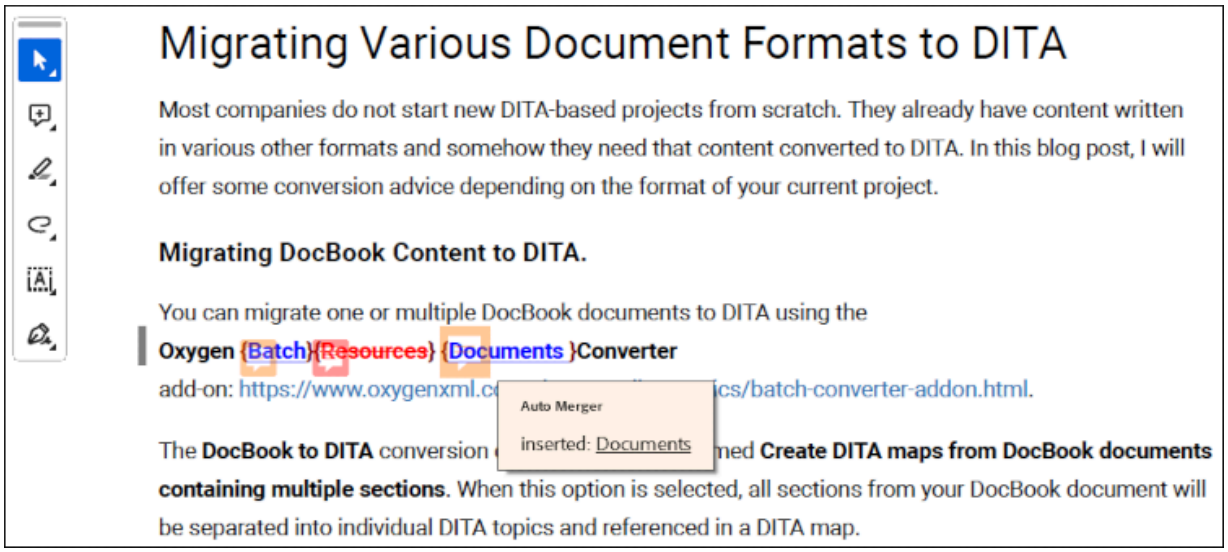
Here is the basic procedure (for this particular example, suppose the resulting merged document is a DITA file):

1. Select the **Merge Documents with Change Tracking Highlights** action that is found in the **Tools > Comparison Tools** menu to invoke the tool. It opens a dialog box where you can specify the documents to merge.
2. In the resulting dialog box, you need to provide the URLs of the base version of the document (**Base document**) and the modified version (**Document to merge with**), and then click the **Merge** button.
3. With the resulting merged document open in the editor, click the **Configure Transformation Scenario(s)** button from the toolbar.
4. Select the default read-only scenario **DITA PDF - based on HTML5 & CSS** and click the **Duplicate** button to create a copy so that you can make a few changes to the default settings.
5. In the resulting **Edit DITA Scenario** dialog box, go to the **Parameters** tab and type "changes" in text filter field above the table of parameters. This will display the three parameters that are responsible for displaying the tracked changes in the resulting PDF and they must all be set to the value of *yes*:
   - `show.changes.and.comments`
   - `show.changes.and.comments.as.changebars`
   - `show.changes.and.comments.as.pdf.sticky.notes`



6. Click **OK**, and with the newly created copy of the scenario selected, click the **Apply associated** button to run the transformation.

   Result: Once the transformation is finished, the resulting PDF is automatically opened in the system's default PDF reader (e.g. Adobe). If you hover the mouse over the presented colored markers, you will notice that the tooltip shows that some are of the type "inserted", while others are of the type "deleted". Text areas and fragments with changes are also marked with gray "change" bars on the left. The changed content is placed between curly brackets and is colored blue or red depending on the type of change (insertion or deletion).



Use Case 3: Compare and Merge Entire Directories

Another use case is to use the **Merge Directories with Change Tracking Highlights** action to merge entire directories instead of specified pairs of XML files.

Here is the basic procedure (for this particular example, suppose you want to review the changes between two versions of an entire DITA project):

1. Select the **Merge Directories with Change Tracking Highlights** action that is found in the **Tools > Comparison Tools** menu to invoke the tool. It opens a dialog box where you can specify the documents to merge.
2. In the resulting dialog box, you need to provide the URLs of the **Base directory**, the **Directory to merge with**, and the **Output directory**.
3. You can optionally select the **Backup the base directory** option. Not that this option is automatically activated and selected in the following cases:
   - The output directory is not specified (the field is left blank).
   - The specified output directory is the base directory itself.

   In these situations, a backup of the base directory will be performed automatically and the backup operation must succeed to proceed with the merge. Otherwise, the merge process is aborted.

4. You can adjust the settings in the **Merge options** section. You can find details for each option in Merge Directories with Change Tracking Highlights: Merge Options *(on page 2892)*. Note that all of these options are enabled by default except for **Create change tracking markers for the XML files to be added**.

   To better understand the merge options presented in this section, note that the merge process has a preliminary phase where the entire structure and the content of the base directory is copied to the output directory.

   Since this example is for reviewing the changes between two versions of an entire DITA project, you would select all options in the **Merge options** section, including the **Create change tracking markers for XML files to be added** option.

5. Click the he **Merge** button to start the process of generating the results of the merge operation. Depending on the number of files in the compared directories and the total number of changes detected, the process may take some time.

   Step Result: The operation report should automatically open in **Author** mode. The listed URLs are actually links that will open the corresponding merged DITA file in the editor. You can inspect the changes and accept or reject them, individually or in bulk.

   The first group of URLs listed represents the group of XML files detected as modified and merged with change tracking highlights.

The modified non-XML file group follows. Since the **Update the modified non-XML files** option was selected, these type of non-XML files from the **Base directory** were replaced by their corresponding files in the **Directory to merge with**.

Next are the XML files that were initially present only in the **Directory to merge with**. They were also added to the **Output directory**, since the **Add the files found only in the directory to merge with** option was selected.

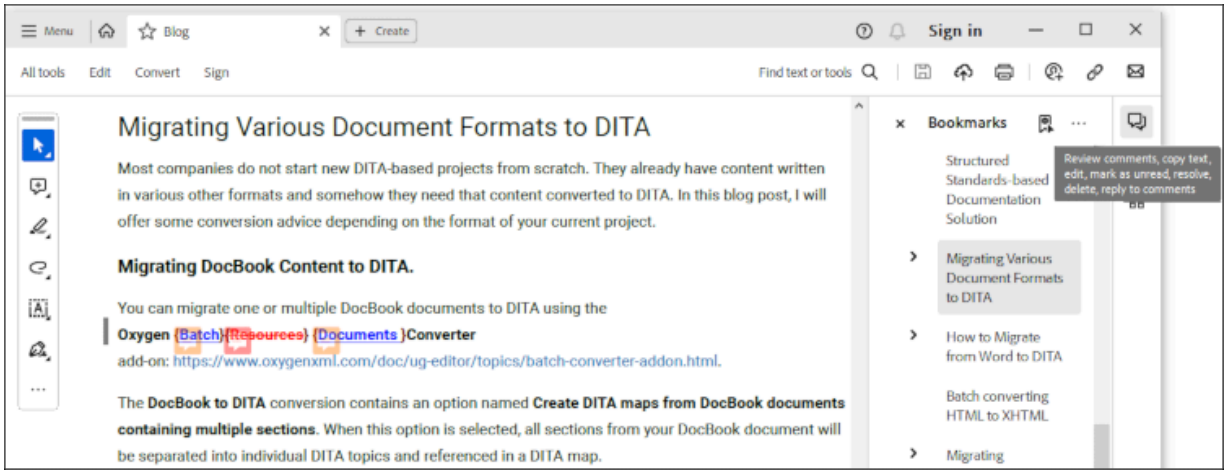
Since the **Create change tracking markers for the XML files to be added** was also selected, change tracking markers of type "entire content added/inserted" were created. Note that it does not make sense to reject that type of change. The **Create change tracking markers for the XML files to be added** option is not intended for the merge process itself, but it is useful if you want to apply various *Oxygen* transformation scenarios to the resulting output directory, as explained later.

Next comes the group of non-XML files initially present only in the **Directory to merge with** and they were also copied to the output directory. Basically, these are resources (usually image or video files) used by the file group listed above. Clicking these types of file links results in opening them in the appropriate application installed on your computer.

The last group listed in the report represents the group of files from the "base directory" that have no longer counterparts in the "directory to merge with". Since the **Delete the files found only in the base directory** option was selected, these files are eventually deleted, even if they were initially copied to the output directory. The links also work for them, opening the associated files from the **Base directory**.

6. Now that you have the directory resulting from the merge operation at your disposal, you can apply a transformation scenario to obtain a PDF document that highlights the changes between the 2 versions. Open the DITA map that resulted from the merge operation in the **DITA Maps Manager**, click the **Configure Transformation Scenario(s)** button in the toolbar of the view, and apply the **DITA Map PDF - based on HTML5 & CSS - Copy** transformation scenario using the same configuration as explained in Use Case 2: Compare Differences Between Two Versions *(on page 2866)*.

   Step Result: Once the transformation is finished, the resulting PDF is automatically opened in the system's default PDF reader (e.g. Adobe).
7. In Adobe, there is a side view identified as **Bookmarks** (on the right or left side, depending of the Adobe version). By selecting **Contents** in this view and then scrolling down, you can hover the mouse over the presented colored markers for the new topics and you will notice that tooltip shows that they are "inserted". You can click on any of these new topics to scroll to the respective topic and you will notice that it is marked with blue in the document (the color used for newly added content). If you continue to scroll down the PDF, you will notice various "insert" and "delete" changes.
8. Click the **Review comments** button on the side stripe of the **Bookmarks** view:



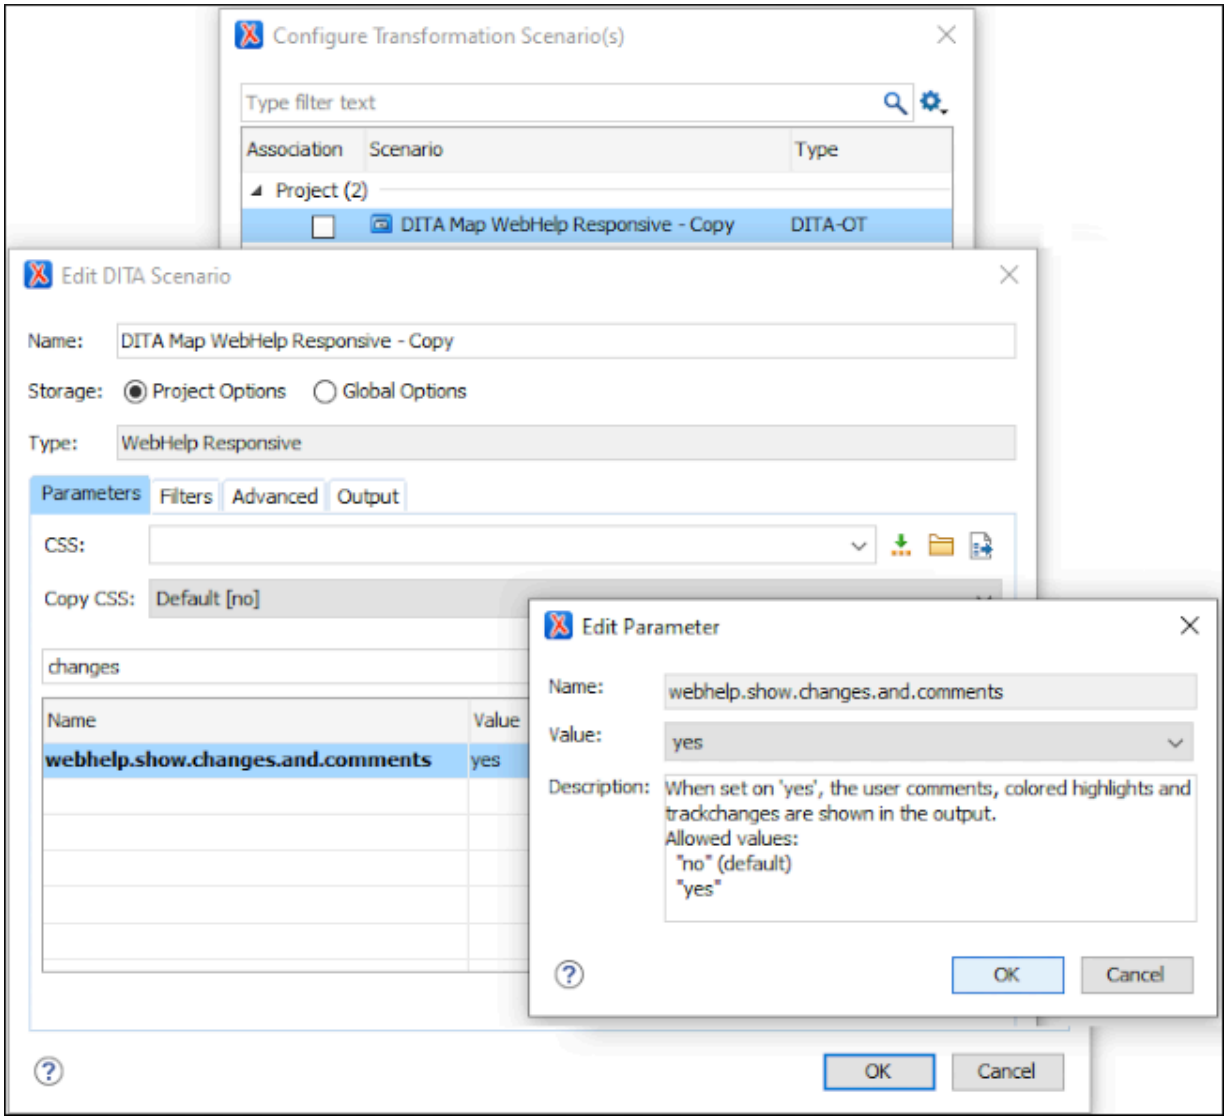
Step Result: A list appears that contains all highlighted changes in the PDF.

9. You can scroll through the list and click on the changes listed to conveniently analyze and review all tracked and highlighted changes between the 2 versions of the DITA project.

WebHelp Responsive Alternative

As an alternative to the **DITA Map PDF - based on HTML5 & CSS** transformation, there are other types of transformations that can be applied to the resulting DITA map, leading to a different kind of output. For example, you can use the **DITA Map WebHelp Responsive** transformation scenario:

1. Select the default read-only scenario **DITA Map WebHelp Responsive** and click the **Duplicate** button to create a copy so that you can make a few changes to the default settings.
2. In the resulting **Edit DITA Scenario** dialog box, go to the **Parameters** tab and type "changes" in text filter field above the table of parameters. Make sure the `webhelp.show.changes.and.comments` parameter is set to *yes*.



3. Click **OK**, and with the newly created copy of the scenario selected, click the **Apply associated** button to run the transformation.

   Step Result: Once the transformation finishes, the resulting WebHelp output is opened in your default Internet browser. By clicking on any of the chapters listed, you can browse the respective content and observe how the changes are rendered. The color code is the same (blue for the changes of the type "added" or "inserted", and red for those of the type "deleted"). The yellow markings on the right side also help to navigate through and analyze/review the highlighted changes.

Resources

For more information about how to merge documents/directories with change tracking highlights, watch our video demonstration:

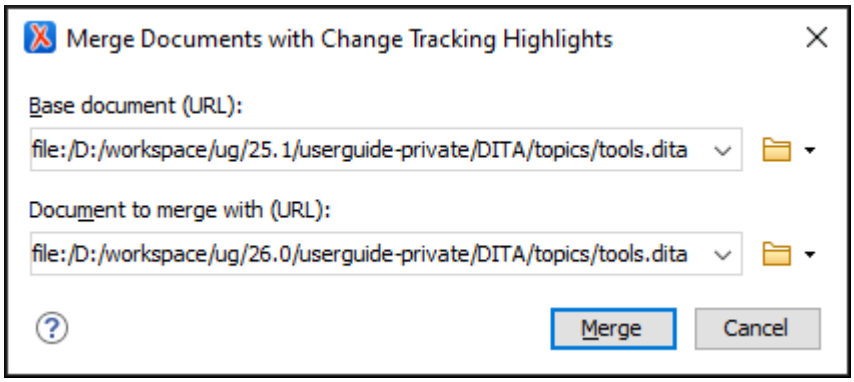
Merge Documents with Change Tracking Highlights

The **Merge Documents with Change Tracking Highlights** tool can be used to merge two XML documents (based on a 2-way mode comparison) and the files involved in the process are merged by saving the

comparison results as documents with highlighted tracked changes that can later be reviewed and accepted or rejected.

To invoke the tool, select the **Merge Documents with Change Tracking Highlights** action that is found in the **Tools > Comparison Tools** menu. It opens a dialog box where you can specify the documents to merge.

Figure 694. Merge Documents with Change Tracking Highlights Dialog Box



The **Merge Documents with Change Tracking Highlights** dialog box contains the following options:

Base document (URL)

Specifies the URL of the base document.

Directory to merge with (URL)

Specifies the URL of the document to merge with.

After specifying the documents to be merged, click the **Merge** button to trigger the operation.

Once the merge operation is complete, the merged document is opened in a new editor tab. With the merged document open in **Author** mode, the highlighted tracked changes can easily be reviewed and accepted or rejected, thus finishing the entire merge process. Initially, the merged document is untitled and not saved. You can choose the name when saving it in a location of your choosing (for example, a common use case is to overwrite the base document with the final resulting merged file).

Additional Notes and Limitations:

- When comparing documents in **Author** mode, changes made in the prolog of XML documents (where the XML version and encoding are declared) are not reported and therefore not considered in the merge process.
- Any "doctype" changes are not reported and therefore not considered in the merge process.
- If one or both of the compared XML documents contain tracked changes (represented internally by custom XML processing instructions), all these modifications are automatically accepted prior to the compare and merge procedures.

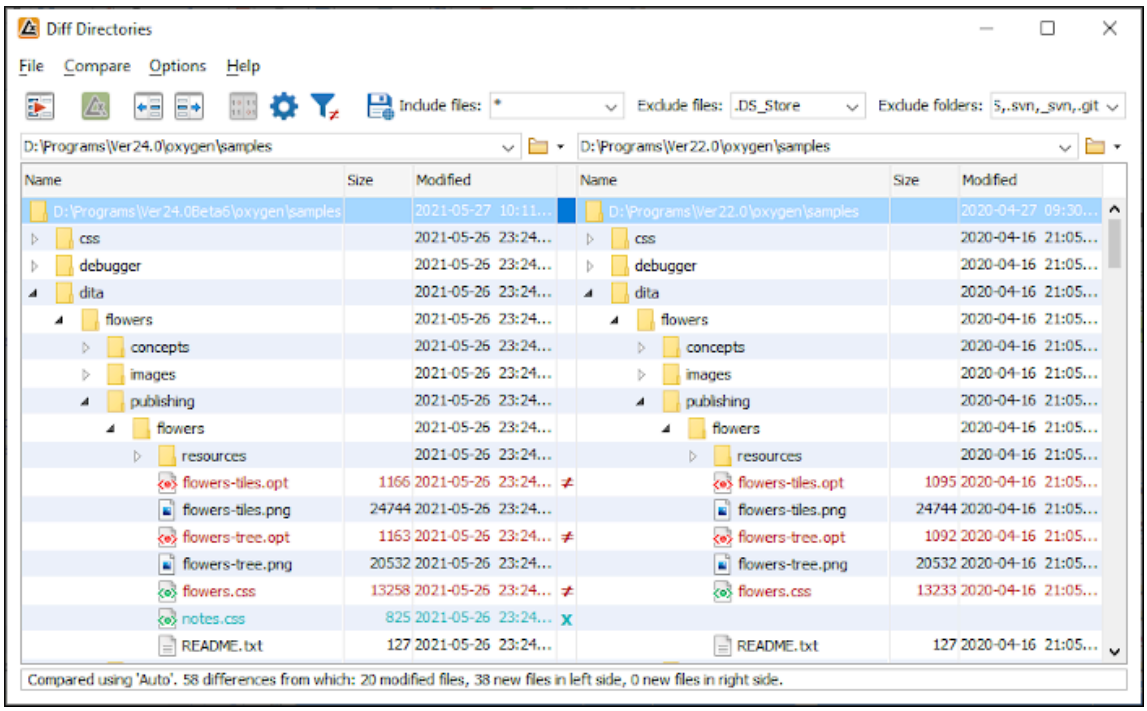
For more information about the merge with change tracking support, see the following resources:

- Video: **Mastering Document Comparisons: A Guide to Generating Tracked Changes Between Two Versions**
- Webinar: **Discover the Power of Diff with Change Tracking**

Compare Directories Tool

The **Compare Directories** tool can be used to compare and manage changes to files and folders within the structure of your directories. The utility is available from the **Tools > Comparison Tools** menu or can be opened as a stand-alone application from the Oxygen XML Editor installation folder (`diffDirs.exe`).

Figure 695. Diff Directories Dialog Box



Starting the Tool from a Command Line

The directory comparison tool can also be started by using command-line arguments. In the installation folder there is an executable shell (`diffDirs.bat` on Windows, `diffDirs.sh` on macOS and Linux). To specify the directories to compare, you can pass command-line arguments using the following construct: `diffDirs.bat/diffDirs.sh [directory path 1] [directory path 2]`.

If you pass only one argument, you are prompted to manually choose the second directory or archive.

Example:

To do a comparison between two directories, the command line would look like this:

Windows

```
diffDirs.bat "c:\documents new" "c:\documents old"
```

Tip:
If there are spaces in the path names, surround the paths with quotes.

Linux

```
diffDirs.sh home/documents1 home/documents2
```

macOS

```
diffDirs.sh documents1 documents2
```

Directory Comparisons

To perform a directory comparison, follow these steps:

1. Select a folder in the left panel and the folder you want to compare it to in the right panel. You can specify the path by using the text field, the history drop-down, or the **Browse for local directory** action in the **Browse** drop-down menu.

   Step Result: The selected directory structures are opened in the two side-by-side panels.
2. To highlight the differences between the two folders, click the **Perform Directories Differencing** button from the toolbar.
3. You can also use the **Diff Options** button to access the **Directories Comparison** preferences page *(on page 298)* where you can configure various options.

To compare the content of two archives, follow these steps:

1. Use the **Browse for archive file** action in the **Browse** drop-down menu to select the archives in the left and right panels.
2. By default, the supported archives are not treated as directories and the comparison is not performed on the files inside them. To make Oxygen XML Editor treat supported archives as directories, select the **Look in archives** option *(on page 299)* in the **Directories Comparison** preferences page.
3. To highlight the differences, click the **Perform Directories Differencing** button from the toolbar.

The directory comparison results are presented using two tree-like structures showing the files and folders, including their name, size, and modification date. A column that contains graphic symbols separates the two tree-like structures. The graphic symbols can be one of the following:

- An **X** symbol, when a file or a folder exists in only one of the compared directories.
- A ≠symbol, when a file exists in both directories but the content differs. The same sign appears when a collapsed folder contains differing files.

The color used for the symbol and the directory or file name can be customized in the **Directories Comparison / Appearance** preferences page *(on page 299)*. You can double-click lines marked with the ≠ symbol to open a **Compare Files** window, which shows the differences between the two files.

The directories that contain files that differ are expanded automatically so that you can focus directly on the differences. You can merge the contents of the directories by using the copy actions. If you double-click (or press **Enter**) on a line with a pair of files, Oxygen XML Editor starts a file comparison *(on page 484)* between the two files, using the **Compare Files** tool.

Toolbar and Contextual Menu Actions of the Compare Directories Tool

The toolbar of the **Compare Directories** tool contains operations that can be performed on the compared directory structure. Some of the toolbar actions are also available in the contextual menu.

Figure 696. Compare toolbar

Toolbar Actions

Perform Directories Differencing

Looks for differences between the two directories displayed in the left and right side of the application window.

Perform Files Differencing

Opens the **Compare Files** tool *(on page 484)* that allows you to compare the currently selected files.

Copy Change from Right to Left

Copies the selected change from the right side to the left side (if there is no file/folder in the right side, the left file/folder is deleted).

Copy Change from Left to Right

Copies the selected change from the left side to the right side (if there is no file/folder in the left side, the right file/folder is deleted).

Binary Compare

Performs a byte-level comparison on the selected files.

Diff Options

Opens the **Directory Comparison** preferences page *(on page 298)* where you can configure various options.

Show Only Modifications

Displays a more uncluttered file structure by hiding all identical files.

Save Results as HTML

Generates an HTML file that contains detailed information about the comparison result.

File and folder filters

Differences can be filtered using three combo boxes: **Include files**, **Exclude files**, and **Exclude folders**. They come with predefined values and are editable to allow custom values. All of them accept multiple comma-separated values and the ***** and **?** wildcards. For example, to filter out all `JPEG` and `GIF` image files, edit the **Exclude files** filter box to read **`*.jpeg`**, **`*.png`**. Each filter includes a drop-down menu with the latest 15 filters applied.

Contextual Menu Actions

Perform Files Differencing

Opens the **Compare Files** tool *(on page 484)* that allows you to compare the currently selected files.

Binary Compare

Performs a byte-level comparison on the selected files.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy Change from Left to Right

Copies the selected difference from the file in the left panel to the file in the right panel.

Open

If the action is invoked on a file, the selected file is opened in Oxygen XML Editor. If the action is invoked on a directory, the selected directory is opened in the default file browser for your particular operating system.

Open in System Application

Opens the selected file in the system application that is associated with that type of file. The action is available when launching the **Compare Directories** tool from the **Tools** menu in Oxygen XML Editor.

Show in Explorer

Opens the default file browser for your particular operating system with the selected file highlighted.

Compare Directories Tool Menus

The menus in the **Compare Directories** tool contain some of the same actions that are on the toolbar, as well as some common actions that are identical to the same actions in the Oxygen XML Editor menus. The menu actions include:

File Menu

 **Save Results as HTML**

Generates an HTML file that contains detailed information about the comparison result. See an example of what the generated report look like in the Generate HTML Report for Directory Comparison topic *(on page 521)*.

Close (Ctrl + W (Command + W on macOS))

Closes the application.

Compare Menu

 **Perform Directories Differencing**

Looks for differences between the two directories displayed in the left and right side of the application window.

 **Perform Files Differencing**

Opens the **Compare Files** tool *(on page 484)* that allows you to compare the currently selected files.

 **Copy Change from Right to Left**

Copies the selected change from the right side to the left side (if there is no file/folder in the right side, the left file/folder is deleted).

 **Copy Change from Left to Right**

Copies the selected change from the left side to the right side (if there is no file/folder in the left side, the right file/folder is deleted).

Options Menu

Preferences

Opens the preferences dialog box that includes numerous pages of options that can be configured.

Menu Shortcut Keys

Opens the **Menu Shortcut Keys** option page where you can configure keyboard shortcuts available for menu items.

Reset Global Options

Resets options to their default values. Note that this option appears only when the tool is executed as a stand-alone application.

Import Global Options

Allows you to import an options set that you have previously exported.

Export Global Options

Allows you to export the current options set to a file.

Help Menu

Help (F1)

Opens a **Help** dialog box that displays the User Manual at a section that is appropriate for the context of the current cursor position.

Use Online Help

If this option is selected, when you select Help or press F1 while hovering over any part of the interface, Oxygen XML Editor attempts to open the help documentation in online mode. If this option is not selected or an internet connection fails, the help documentation is opened in offline mode.

Report problem

Opens a dialog box that allows the user to write the description of a problem that was encountered while using the application. You can change the URL where the reported problem is sent by using the `com.oxygenxml.report.problems.url` system property. The report is sent in XML format through the `report` parameter of the POST HTTP method.

Support Center

Opens the Oxygen XML Editor Support Center web page in a browser.

Compare Images

You can use the **Compare Directories** tool to compare images. If you double-click a line that contains two different images, the **Compare images** window is displayed. This dialog box presents the images in the left and right sides, scaled to fit the available view area. You can use the contextual menu actions to scale the images to their original size or scale them down to fit in the view area.

The supported image types are: *GIF*, *JPG*, *JPEG*, *PNG*, and *BMP*.

Compare Directories Against a Base (3-Way) Tool

The **Compare Directories Against a Base (3-way)** tool allows you to perform three-way comparisons on directories to help you identify and merge changes between multiple modifications of the same directory structure. It is especially helpful for teams that have multiple authors contributing documents to the same directory system. It offers information about conflicts and changes, and includes actions to easily merge, accept, overwrite, or ignore changes to the directory system.

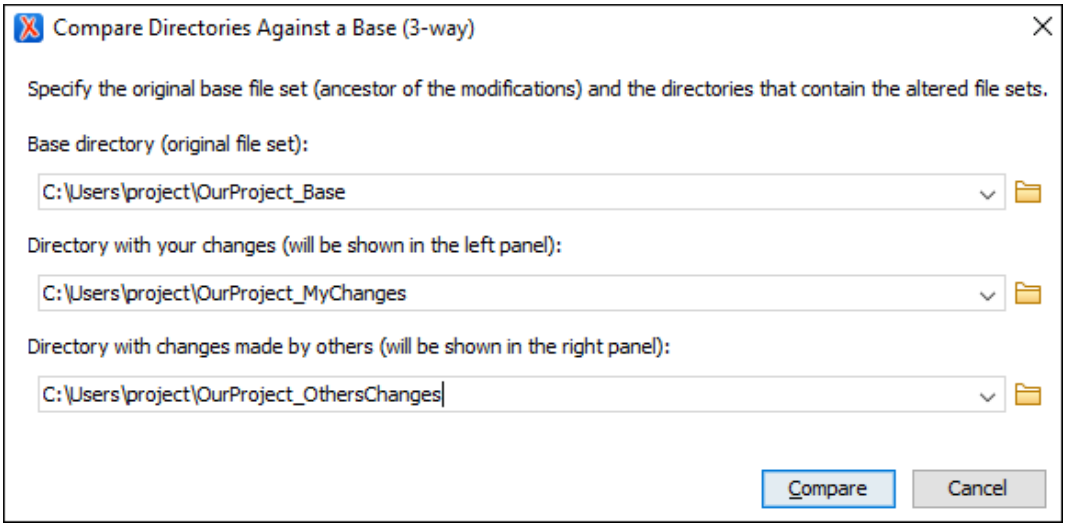
How to Perform 3-Way Directory Comparisons

To perform a 3-way directories comparison, follow these steps:

1. Select **Compare Directories Against a Base (3-way)** from the **Tools > Comparison Tools** menu.

   Step Result: This opens a dialog box that allows you to select the 3 file sets that will be used for the comparison.

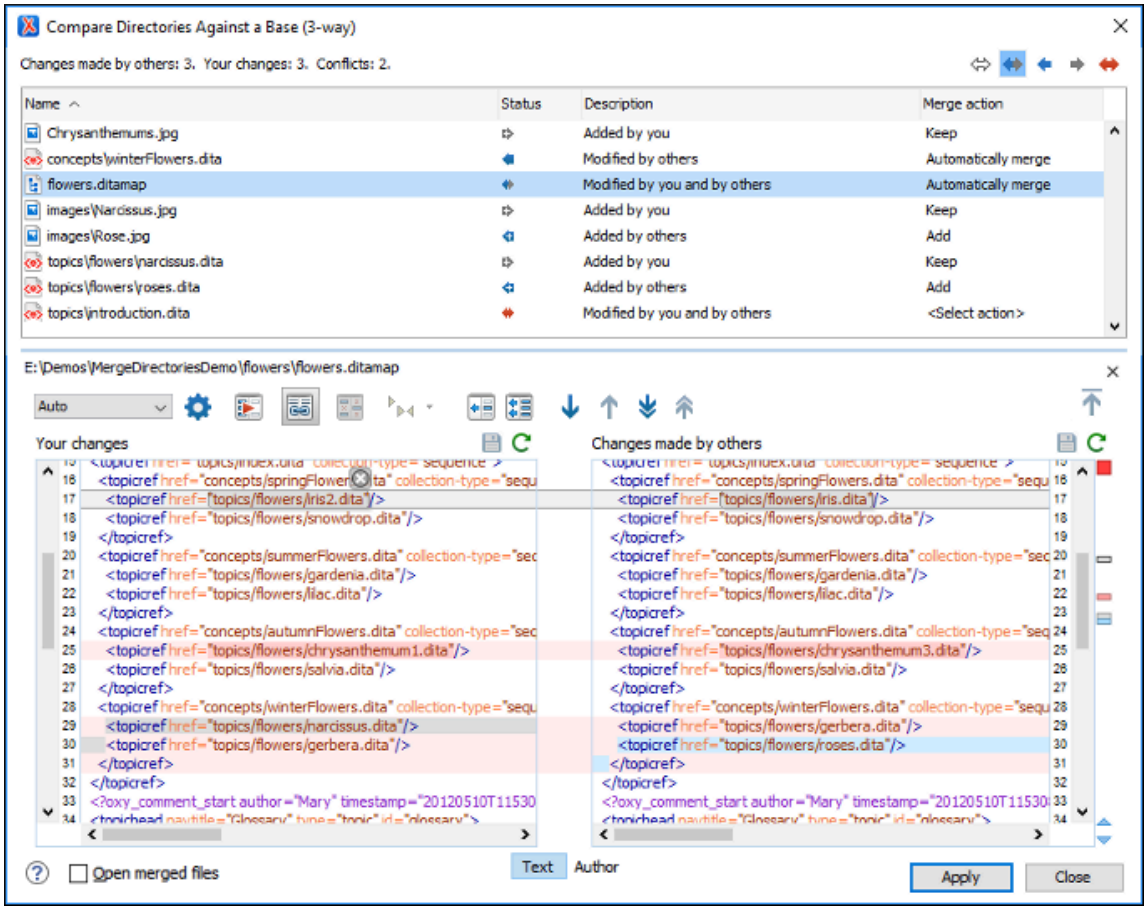
   Figure 697. Compare Directories Against a Base File Set Chooser

2. Select the file sets to be compared:
   - **Base directory** - This is the original (base) file set before any modifications were made by you or others.
   - **Directory with your changes** - This is the file set with changes that you have made. This file set will be displayed in the left panel in the comparison tool.
   - **Directory with changes made by others** - This is the file set with changes made by others that you want to merge with your changes. This file set will be displayed in the right panel in the comparison tool.
3. Click the **Compare** button to compare the file sets and open the comparison and merge tool.
4. Use the features and actions described in the next section to identify and merge the changes.

3-Way Directory Comparison and Merge Tool

Figure 698. Comparison and Merge Tool



The 3-way directory comparison and merge tool includes the following information, features, and actions:

Number of Changes and Conflicts

The first thing you see in the top-left corner of the tool is the grand total of all the changes made by others, changes made by you, and the number of conflicts.

Filter Buttons

In the top-right corner you can use the toggle buttons to filter the list of modifications:

Show all files

Use this button to show all modified and unmodified files, as well as conflicts.

Show only files modified by you and others

Filters the list to show all files that have been modified, including conflicts.

Show only files modified by others

Filters the list to only show the files that were modified by others.

Show only files modified by you

Filters the list to only show the files that were modified by you.

Show only conflicting files

Filters the list to only show files that contain conflicts.

List of Files Panel

This panel shows the list of files in the compared file sets based upon the filter button that is selected. This panel includes the following sortable columns:

- **Name** - The file names.
- **Status** - An icon that represents the file status. Red icons indicate some sort of conflict. Gray icons indicate modifications made by you. Blue icons indicate modifications made by others.
- **Description** - A description of the file status.
- **Merge Action** - This column provides a drop-down menu for each file that allows you to choose some merge actions depending upon its status. A default action is always set to **Automatically merge** the changes made by others with your changes. If there is a conflict, the default is **<Select action>** and you are required to make a selection. Click this column to access the drop-down menu where you can make a selection. The same actions are available in the contextual menu.

Tip:
If the solution proposed in the **Merge Action** column for any particular file is not satisfactory, you can change it directly in that column (even if that file is not selected) without automatically re-triggering the comparison (except for in certain cases where re-triggering the comparison is necessary).

You can click a file to open it in the file comparison panel (the file from your file set is shown in the left panel while the file from the file set with changes made by others is shown in the right panel). For image files, the comparison panel shows a preview of the image. For other binary files, a preview is not available and you will just see its status.

File Comparison Panels

If you click a file in the top panel, the file is opened in this file comparison section. The file from your file set is shown in the left panel and the file from the other file set is shown in the right panel.

Note:
If Oxygen XML Editor does not recognize the file type, a dialog box will be displayed that allows you to select the type of editor you want it to be associated with for this comparison (if you want Oxygen XML Editor to remember this association, you can select the **Associate file type with editor** option at the bottom of the dialog box).

This panel includes the following information and toolbar actions:

File Path

The first thing you see in this panel is the file path where merge actions will be applied if you make changes.

Close

Closes the file comparison panel.

Algorithm Drop-down Menu

This drop-down menu allows you to select one of the following diff algorithms to be used for file comparisons:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** comparison mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Diff Options

Opens the **Files Comparison** preferences page *(on page 295)* where you can configure various options.

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Synchronized scrolling

Toggles synchronized scrolling. When toggled on, a selected difference can be seen in both panels.

Ignore Whitespaces

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces. This option is not available when the file comparison is in **Author** mode.

Tags Display Mode

Allows you to select the amount of markup to be displayed in the **Author** visual mode. You can choose between: **Full Tags with Attributes**, **Full Tags**,

Block Tags, **Block Tags without Element Names**, **Inline Tags**, **Partial Tags**, or **No Tags**.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Next Block of Changes (Ctrl + Period (Command + Period on macOS))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

> **Note:**
> A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on macOS))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on macOS))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on macOS))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

First Change (Ctrl + B (Command + B on macOS))

Jumps to the first change.

Left-Side File (Your changes)

Above the panel you can see the file path and the following two buttons:

Save

Saves changes made to the file.

Reload

Reloads the file.

Right-Side File (Changes made by others)

Above the panel you can see the file path and the following two buttons:

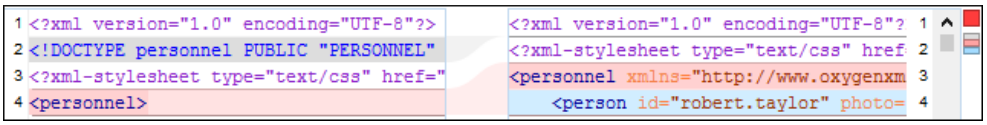
Reload

Reloads the file.

Displaying Changes in the File Comparison Panels

The line numbers on each side and colored marks on the right-side vertical stripe help you to quickly identify the locations of the differences. Adjacent changes are grouped into blocks of changes.

Figure 699. File Comparison Panels



The differences are also highlighted in several colors, depending on the type of change, and dynamic lines connect the compared fragments in the middle section between the two panes. The highlighting colors can be customized in the **Files Comparison / Appearance** preferences page *(on page 297)*, but the default colors and their shades mean the following:

- **Pink** - Identifies modifications on either side.
- **Gray** - Identifies an addition of a node in the left side (your outgoing changes).
- **Blue** - Identifies an addition of a node in the right side (incoming changes).
- **Lighter Shade** - Identifies blocks of changes that can be merged in their entirety.
- **Darker Shade** - Identifies specific changes within the blocks that can be merged more precisely.

Direct Editing Actions in the File Comparison Panels

In addition to selecting merge actions from the drop-down menus in the **Merge Action** column in the top panel, you can also edit the files directly in the left pane (your local changes). The two editors are constantly synchronized and the differences are refreshed when you save the modified document (**Save** button or **Ctrl+S**) or when you click the **Perform File Differencing** button.

A variety of actions are available in the contextual menu in both editing panes. The tool also includes some inline actions to help you merge, copy, or remove changes. When you select a change, the following inline action widgets are available, depending on the type of change:

Append right change to left

Copies the content of the selected change from the right side and appends it on the left side.

Copy change from right to left

Replaces the content of a change in the left side with the content of the change in the right side.

Remove change

Removes the change from the left side.

Anytime you save manual changes (**Save** button or **Ctrl+S**), the selection in the **Merge Action** column in the top panel automatically changes to **Use merged** and a copy of the original file is kept so that you can revert to the original file if necessary. To discard your manual changes and revert to your original changes, select a different action in the **Merge Action** drop-down menu.

Open Merged Files

If you select this option, all the files that will be modified by the merge operation will be opened in the editor after the operation is finished.

Applying Changes

When you click the **Apply** button, all the merge actions you have selected and the changes you have made will be processed.

If there are unresolved conflicts (conflicts where no merge action is selected in the **Merge Action** drop-down menu), a dialog box will be displayed that allows you to choose how to solve the conflicts. You can choose between the following:

- **Keep your changes** - If you select this option and then click **Apply**, your local changes will be preserved for the unresolved conflicts.
- **Overwrite your changes** - If you select this option and then click **Apply**, your local changes will be overwritten with the changes made by others, for the unresolved conflicts.
- **Cancel** - You can click the **Cancel** button to go back to the merge tool to resolve the conflicts individually.

Canceling Changes

If you click the **Cancel** button at the bottom of the merge tool, all the changes you made in the tool will be lost.

Author Visual Mode

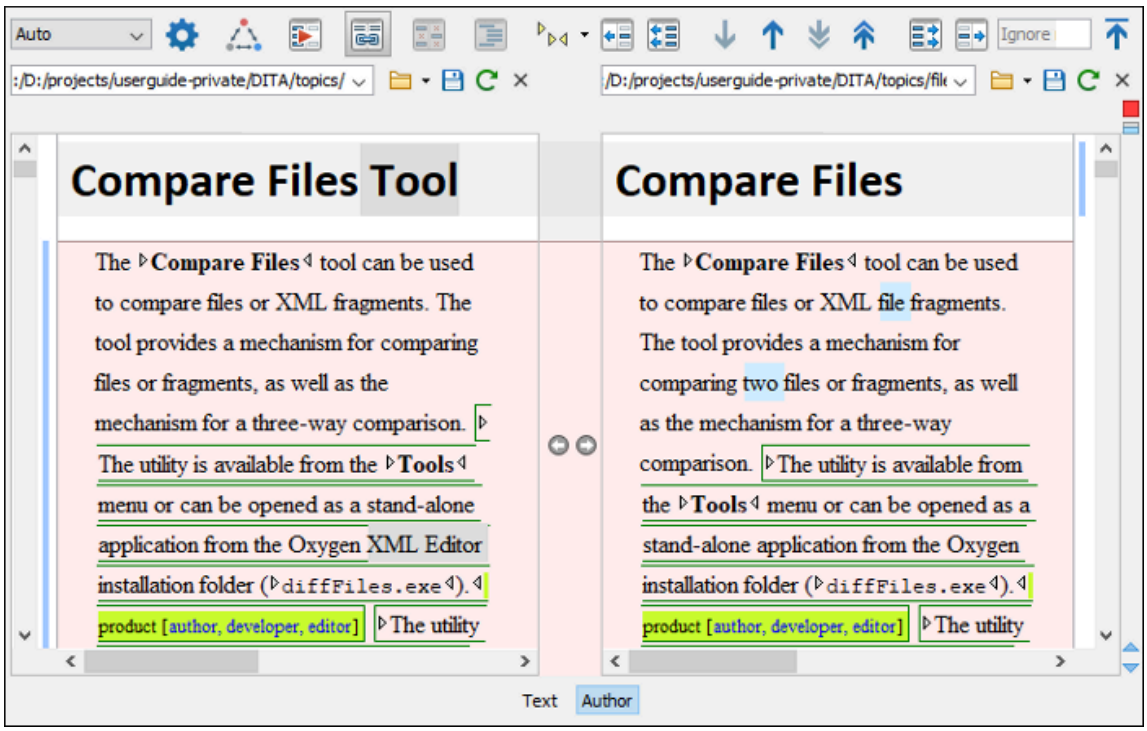
The **Comparison and Merge** tool includes an **Author** mode that displays the files in a visual mode similar to the **Author** editing mode in *Oxygen XML Editor/Author*. This makes it easier to see how the compared changes will look in the final output. This visual mode is available when the compared files are detected as being XML. To determine whether the files are initially opened in the merge tool's **Text** or **Author** mode, it

detects the **Initial Edit Mode** in the *Document Type Association* configuration *(on page 149)* and the mode the files were last opened in *Oxygen XML Editor/Author*.

Note:
This mode is not available if the **Enable file comparison in Author mode** option *(on page 295)* is not selected in the **Diff > Files Comparison** preferences page.

This visual mode includes unique features such as a **Tags Display Mode** drop-down button *(on page 2883)* on the toolbar that allows you to select the amount of tags to display in this visual mode. This mode also presents differences that were made using the **Track Changes** feature (although the **Track Changes** feature is not available in the comparison tool).

Figure 700. File Comparison Tool - Author Mode



Author Mode Algorithms

The visual **Author** mode offers the following diff algorithms to compare files:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Author Mode Second-Level Comparisons

The visual **Author** mode automatically performs a second-level comparison for the **XML Fast** and **XML Accurate** algorithms. After the first comparison is finished, the second-level comparison is processed on text nodes using a word level comparison, meaning that it looks for identical words. This second-level comparison makes it easier to spot precise differences and you can merge or reject the precise modifications.

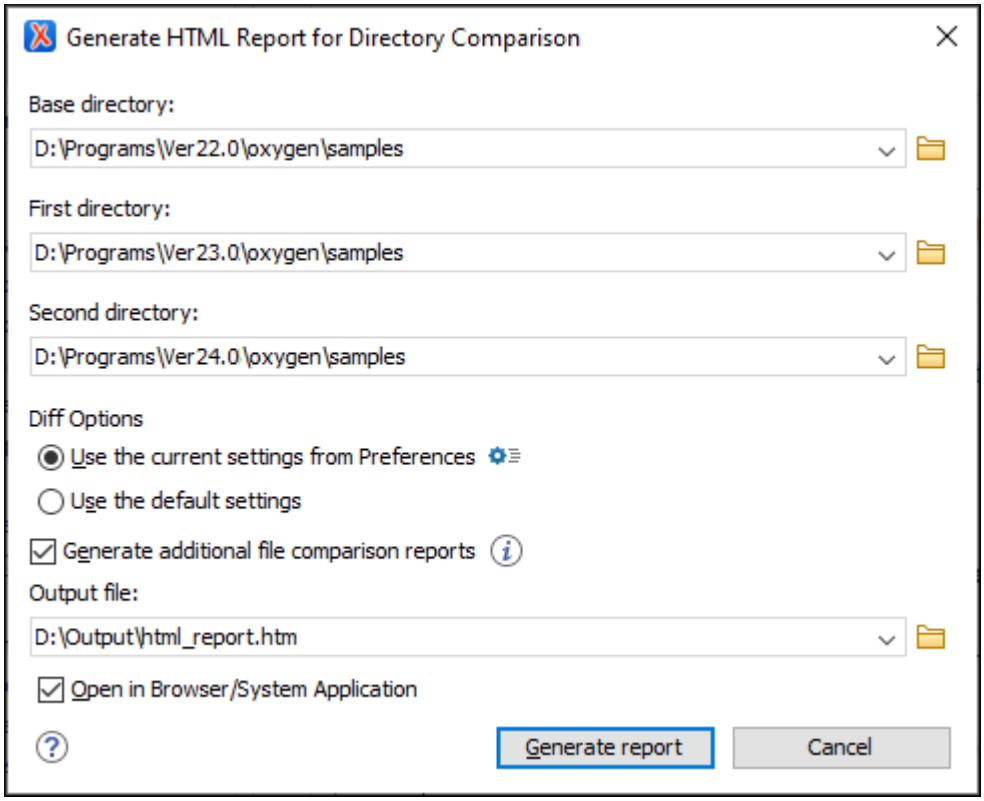
Compare Files Tool *(on page 484)*

Generate HTML Report for Directory Comparison

The **Generate HTML report for directory comparison** tool can be used to generate a report in the form of an HTML file that contains the results of a directory comparison (for either 2-way or 3-way comparisons). The **Generate HTML report for directory comparison** action for invoking the tool can be found in the **Tools > Comparison Tools** menu. It opens a dialog box where you can specify the directories to compare as well as some other options.

Figure 701. Generate HTML Report for Directory Comparison Dialog Box



The **Generate HTML report for directory comparison** dialog box contains the following options:

Base directory

Specifies the path of the base directory that the other two directories will be compared against in a 3-way comparison. This field should be left empty for 2-way comparisons.

First directory

Specifies the path of the first directory to be included in the comparison.

Second directory

Specifies the path of the second directory to be included in the comparison.

Diff options

Specifies which option set to use for generating the comparison report. If you choose **Use the current settings from Preferences**, the options set in the **Directories Comparison** preferences page *(on page 298)* and the include/exclude filter options in the **Compare Directories** tool *(on page 507)* are taken into account when generating the comparison result. You can also click the **Diff options** button to open the **Directories Comparison** preferences page where you can see or modify the current settings. If you choose **Use the default settings**, the default values for all settings are used.

Generate additional file comparison reports

Generates further comparison reports for all non-binary modified file pairs and provides links to them in the main report (in the middle cells of the results table). See the example below *(on page 2890)*. These additional file comparison reports are saved to a directory that will have the same parent directory and the same name as the output file provided, suffixed by "**-OXY-FC-REPORTS**". The links created in the main report are relative to this directory. If the main HTML report is later copied or moved to another location, to retain full functionality in the browser, the directory with the additional file comparison reports must also be copied/moved to the same location.

Note:
Generating additional file comparison reports could significantly increase the execution time. A progress tracker for the whole operation is available.

Tip:
An XPath expression specified in the **Ignore nodes by XPath** text field within the **Files Comparison** preferences page *(on page 295)* is now taken into account if you enable the **Generate additional file comparison reports** option.

Output file

Specifies the path for an output file to save the comparison results file.

Open in Browser/System Application

Opens the comparison results file in the browser or system application that is associated with HTML files.

After clicking the **Generate report** button, a report in the form of an HTML file is generated with details about the comparison results.

Compare Directories Tool *(on page 504)*
Compare Directories Against a Base (3-Way) Tool *(on page 510)*
Compare Files Tool *(on page 484)*

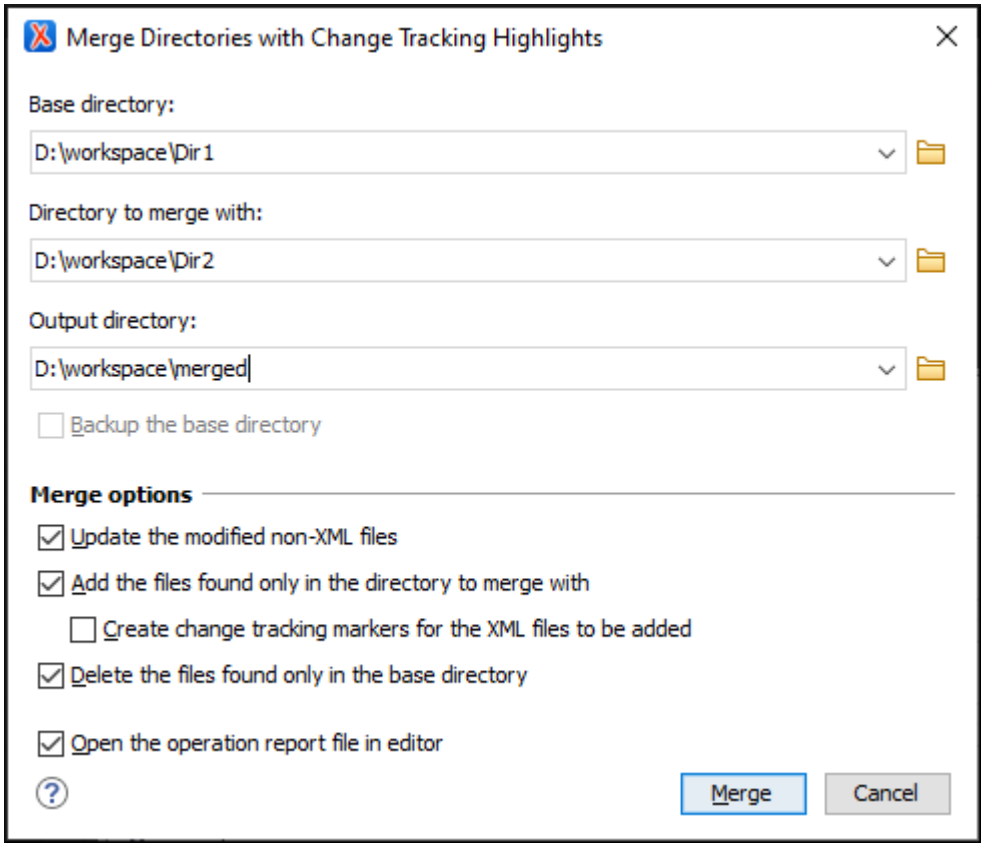
Merge Directories with Change Tracking Highlights

The **Merge Directories with Change Tracking Highlights** tool can be used to merge two directories (based on a 2-way mode comparison) and all pairs of modified XML files involved in the process are merged by saving the comparison results as documents with highlighted tracked changes that can be later reviewed and accepted or rejected.

All other detected situations are treated based on several options that are applicable to both XML and non-XML files, or another option that is applicable only to non-XML files.

To invoke the tool, select the **Merge Directories with Change Tracking Highlights** action that is found in the **Tools > Comparison Tools** menu. It opens a dialog box where you can specify the directories to merge and the output directory to save the results, as well as some other options.

Figure 704. Merge Directories with Change Tracking Highlights Dialog Box



The **Merge Directories with Change Tracking Highlights** dialog box contains the following options:

Base directory

Specifies the path of the base directory.

Directory to merge with

Specifies the path of the directory to merge with.

Output directory

Specifies the path of the directory where the merge operation results are saved to. You can leave this field blank and the merge results will be saved in the base directory by overwriting it, or you can choose a separate output directory.

Note:
You cannot choose the same directory specified as the directory to merge with as the output directory.

Backup the base directory

If this option is selected, a backup copy is saved on your hard disk when the operation completes. This option is automatically activated and selected in the following cases:

- The output directory is not specified (the field is left blank).
- The specified output directory is the base directory itself.
- In both of the above situations, a backup of the base directory will be performed automatically and the backup operation must succeed to proceed with the merge. Otherwise, the merge process being aborted.

Note:
The backup copy will have the same parent directory as the base directory and its name will be the name of the base directory suffixed by ".OXY.BAK".

Merge options

The merge process has a preliminary phase where the entire structure and the content of the base directory is copied to the output directory. The following merge options are available:

Update the modified non-XML files

If this option is selected, all files in the output directory that are copies of non-XML files in the base directory are replaced by their corresponding files in the directory to merge with. Otherwise, they remain unchanged.

Add the files found only in the directory to merge with

If this option is selected, all files that are only present in the directory to merge with are also added to the output directory.

Create change tracking markers for the XML files to be added

This option can only be used in conjunction with the **Add the files found only in the directory to merge with** option. Select this option

if you want to create change tracking markers for the XML files that are only present in the directory to merge with and will be added to the output directory. Although these files have no counterparts in the base directory, change tracking markers of type "entire content added/inserted" will be created.

The option is not necessarily intended for the merge process itself, but it is useful if you want to apply various *Oxygen* transformation scenarios to the resulting output directory. For example, if you merge 2 versions of a DITA project and then want a PDF to highlight the changes between those versions, you can apply a transformation on the resulting `ditamap` file. This option results in presenting the new DITA files as "added content" in the resulting PDF.

Delete the files found only in the base directory

If this option is selected, all files that are only present in the base directory and initially copied to the output directory are deleted. Otherwise, they are preserved.

Open the operation report file in editor

Opens the merge operation report (XML file) in the editor.

Once the merge operation is complete, loading the report file in Oxygen XML Editor provides additional functionality. Aside from the fact that the report provides an overview of the merge process, it also provides links to all the files in the resulting output directory. This is helpful for generating XML documents with tracked changes. For example, you can use the respective links to load these XML files in **Author** mode to review the tracked changes and accept or reject them. This phase of reviewing and manually merging the XML files is typically the final phase of the entire merge procedure.

Figure 705. Example of an Operation Overview Report File

Syncro SVN Client (Deprecated)

The Syncro SVN Client is a client application for the Apache Subversion™ version control system, compatible with Subversion 1.6, 1.7, and 1.8 servers. It manages files and directories that change over time and are stored in a central repository. The version control repository is much like an ordinary file server, except that it remembers every change ever made to your files and directories. This allows you to access older versions of your files and examine the history of how and when your data changed.

To start Syncro SVN Client, go to **Tools > SVN Client**.

Attention:
The Syncro SVN Client that comes bundled with Oxygen XML Editor is considered deprecated as of version 21.0.

Main Window

This section explains the main window of Syncro SVN Client.

Views

The main window consists of the following views:

- **Repositories** view *(on page 2985)* - Allows you to define and manage Apache Subversion™ repository locations.
- **Working Copy** view *(on page 2990)* - Allows you to manage with ease the content of the working copy.
- **History** view *(on page 3005)* - Displays information (author name, revision number, commit message) about the changes made to a resource during a specified period of time.
- **Editor** view *(on page 3011)* - Allows you to edit various types of text files, with full syntax-highlight.
- **Annotations** view *(on page 3012)* - Displays a list with information regarding the structure of a document (author and revision for each line of text).
- **Compare** view *(on page 3014)* - Displays the differences between two revisions of a text file from the working copy.
- **Image Preview** panel *(on page 3018)* - Allows you to preview standard image files supported by Syncro SVN Client: JPG, GIF and PNG.
- **Compare Images** view *(on page 3018)* - Displays two images side by side.
- **Properties** view *(on page 3018)* - Displays the SVN properties of a resource under version control.
- **Console** view *(on page 3020)* - Displays information about the currently running operation, similar with the output of the Subversion command-line client.
- **Dynamic Help** view *(on page 3020)* - Shows information about the currently selected view.

The main window's status bar presents in the left side the operation in progress or the final result of the last performed action. In the right side there is a progress bar for the running operation and a stop button to cancel the operation.

SVN Main Menu

The main menu of the Syncro SVN Client is composed of the following menus:

File Menu

New submenu:

New File

This operation creates a new file as a child of the selected folder from the **Repositories** view *(on page 2985)* tree or the **Working Copy** view *(on page 2990)* tree, depending on the view that was last used. Note that for the **Working Copy** view *(on page 2990)*, the file is added to *version control* only if the selected folder is under *version control*.

New Folder(Ctrl + Shift + F (Command + Shift + F on macOS))

This operation creates a new folder as a child of the selected folder from the **Repositories** view *(on page 2985)* tree or the **Working Copy** view *(on page 2990)* tree, depending on the view that was last used. Note that for the **Working Copy** view *(on page 2990)*, the file is added to *version control* only if the selected folder is under *version control*.

New External Folder (Ctrl + Shift + W (Command + Shift + W on macOS))

This operation allows you to add a new external definition on the selected folder. An external definition is a mapping of a local directory to a URL of a versioned directory *(on page 3025)*, and ideally a particular revision, stored in the `svn:externals` property of the selected folder.

Tip:
You can specify a particular revision of the external item by using a *peg* revision *(on page 3027)* at the end of the URL (for example, `URL@rev1234`). You can also use peg revisions to access external items that were deleted, moved, or replaced.

The URL used in the external definition format can be relative. You can specify the repository URL that the external folder points to by using one of the following relative formats:

- **../** - Relative to the URL of the directory that the `svn:externals` property is set.
- **^/** - Relative to the root of the repository where the `svn:externals` property is versioned.
- **//** - Relative to the scheme of the URL of the directory that the `svn:externals` property is set.
- **/** - Relative to the root URL of the server that has the `svn:externals` property versioned.

Important:
To change the target URL of an external definition, or to delete an external item, do the following:

1. Modify or delete the item definition found in the `svn:externals` property that is set on the parent folder.
2. For the change to take effect, use the **Update** operation on the parent folder of the external item.

Note:
Syncro SVN Client does not support definitions of local relative external items.

Open (Ctrl + O (Command + O on macOS))

This action opens the selected file in an editor where you can modify it. The action is active only when a single item is selected. The action opens a file with the internal editor or the external application associated with that file type. This action works on any file selection from the **Repositories** view *(on page 2985)*, **Working Copy** view *(on page 2990)*, **History** view *(on page 3005)*, or **Directory Change Set** view *(on page 3010)*, depending on the view that was last used to invoke it. In the case of a folder, the action opens the selected folder with the system application for folders (for example, Windows Explorer on Windows or Finder on macOS). Note that opening folders is available only for folders selected in the **Working Copy** view *(on page 2990)*.

Open with(Ctrl + Shift + O (Command + Shift + O on macOS))

Displays the **Open with** dialog box for specifying the editor where the selected file is opened. If multiple files are selected only external applications can be used to open the files. This action works on any file selection from **Repositories** view *(on page 2985)*, **Working Copy** view *(on page 2990)*, **History** view *(on page 3005)*, or **Directory Change Set** view *(on page 3010)*, depending on the view that was last used to invoke it.

Show in Explorer/Show in Finder

Opens the parent directory of the selected working copy file and selects the file.

 **Save (Ctrl + S (Command + S on macOS))**

Saves the local file currently opened in the editor or the **Compare** view.

Save as

Saves any file selected in the **Repositories**, **History**, or **Directory Change Set** view.

Copy URL Location (Ctrl + Alt + U (Command + Option + U on macOS))

Copies the URL location of the resource currently selected in the **Repositories** view to clipboard.

 **Copy to**

Copies the currently selected resource, either in **Repositories** or **Working copy** view, to a specified location.

Note:
This action can also be used from **History** and **Directory Change Set** views to recover older versions of a repository item.

Move to(Ctrl + M (Command + M on macOS))

Moves the currently selected resource, either in **Repositories** or **Working copy** view, to a specified location.

Rename(F2)

Renames the resource currently selected, either in **Repositories** or **Working copy** view.

 **Delete (Delete)**

Deletes the resource currently selected either, in **Repositories** or **Working copy** view.

Locking:

- **Scan for locks (Ctrl + L (Command + L on macOS))** - Contacts the repository and recursively obtains the list of locks for the selected resources. A dialog box containing the locked files and the lock description will be displayed. This is only active for resources under *version control*. For more details see Scanning for locks *(on page 2926)*.
-  **Lock (Ctrl + K (Command + K on macOS))** - Allows you to lock certain files that need exclusive access. You can write a comment describing the reason for the lock and you can also force (*steal*) the lock. This action is

active only on files under *version control*. For more details on the use of this action see Locking a file *(on page 2927)*.

- **Unlock (Ctrl + Alt + K (Command + Option + K on macOS))** - Releases the exclusive access to a file from the repository. You can also choose to unlock it by force (*break the lock*).

Show SVN Properties (Ctrl + P (Command + P on macOS))

Opens the **Properties** view *(on page 3018)* and displays the SVN properties for a selected resource from **Repositories** view *(on page 2985)* or **Working Copy** view *(on page 2990)*, depending on the view that was last used to invoke it.

Show SVN Information (Ctrl + I (Command + I on macOS))

Provides additional information for a selected resource. For more details, go to Obtain information for a resource *(on page 2943)*.

Exit (Ctrl + Q (Command + Q on macOS))

Closes the application.

Edit Menu

Undo (Ctrl + Z (Command + Z on macOS))

Undo edit changes in the local file that is currently opened in the editor or the **Compare** view.

Redo (Ctrl + Y (Command + Y on macOS))

Redo edit changes in the local file that is currently opened in the editor or the **Compare** view.

Cut (Ctrl + X (Command + X on macOS))

Cut selection from the local file that is currently opened in the editor view or the **Compare** view to clipboard.

Copy (Ctrl + C (Command + C on macOS))

Copy selection from the local file that is currently opened in the editor or the **Compare** view to clipboard.

Paste (Ctrl + V (Command + V on macOS))

Paste selection from clipboard into the local file that is currently opened in editor or the **Compare** view.

Find/Replace (Ctrl + F (Command + F on macOS))

Perform find and replace operations in the local file that is currently opened in the editor or the **Compare** view.

Find Next (F3)

Go to the next match using the same find options of the last find operation. This action runs in the editor panel and in any non-editable text area (for example, the **Console** view).

Find Previous (Shift + F3)

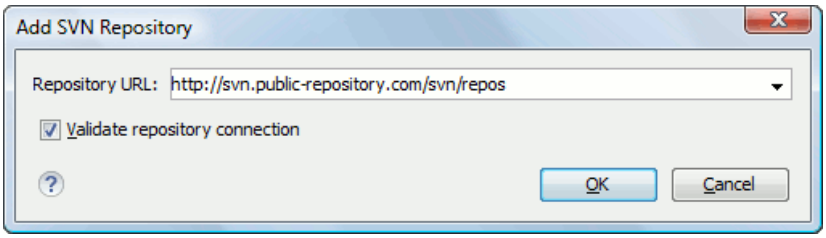
Go to the previous match using the same find options of the last find operation. This action runs in the editor panel and in any non-editable text area (for example, the **Console** view).

Repository Menu

New Repository Location (Ctrl + Alt + N (Command + Option + N on macOS))

Displays the **Add SVN Repository** dialog box. This dialog box allows you to define a new repository location.

Figure 707. Add SVN Repository Dialog Box



If the **Validate repository connection** option is selected, the URL connection is validated before being added to the **Repositories** view.

Edit Repository Location (Ctrl + Alt + E (Command + Option + E on macOS))

Context-dependent action that allows you to edit the selected repository location using the **Edit SVN Repository** dialog box. It is active only when a repository location root is selected.

Change the Revision to Browse (Ctrl + Alt + B (Command + Option + B on macOS))

Context-dependent action that allows you to change the selected repository revision using the **Change the Revision to Browse** dialog box. It is active only when a repository location root is selected.

Remove Repository Location (Ctrl + Alt + R (Command + Option + R on macOS))

Allows you to remove the selected repository location from the view. It shows you a confirmation dialog box before removal. It is active only when a repository location root is selected.

Refresh (F5)

Refreshes the resource selected in the **Repositories** view.

Check out (Ctrl + Alt + O (Command + Option + O on macOS))

Allows you to create a working copy from a repository directory, on your local file system. To read more about this operation, see Check out a working copy *(on page 2916)*.

Export

Opens the **Export** dialog box *(on page 2980)* that allows you to configure options for exporting a folder from the repository to the local file system.

Import:

Import folder (Ctrl + Shift + L (Command + Shift + L on macOS))

Allows you to import the contents of a specified folder from the file system into the selected folder in a repository. To read more about this operation, see the section Importing resources into a repository *(on page 2979)*.

> **Note:**
> The difference between the **Import folder** and **Share project** actions is that the latter also converts the selected directory into a working copy.

Import Files (Ctrl + Shift + I (Command + Shift + I on macOS))

Imports the files selected from the files system into the selected folder in the repository.

Working Copy Menu

Working Copies Manager (on macOS)

Opens a dialog box with a list of working copies that the Apache Subversion™ client is aware of. In this dialog box you can add existing working copies or remove those that are no longer needed.

Switch to

Selects one of the following view modes: **All Files**, **Modified**, **Incoming**, **Outgoing**, or **Conflicts**.

Refresh (F5)

Refreshes the state of the selected resources or of the entire working copy (if there is no selection).

Synchronize (Ctrl + Shift + S (Command + Shift + S on macOS))

Connects to the repository and determines the working copy and repository changes made to the selected resources. The application switches to **Modified** view mode if the **Always switch to 'Modified' mode** option *(on page 292)* is selected.

Update (Ctrl + U (Command + U on macOS))

Updates all the selected resources that have incoming changes to the HEAD revision. If one of the selected resources is a directory then the update for that resource will be recursive.

Update to revision/depth

Allows you to update the selected resources from the working copy to an earlier revision from the repository. You can also select the update *depth* for the current folder. You can find out more about the *depth* term in the sparse checkouts *(on page 2984)* section.

Commit

Collects the outgoing changes from the selected resources in the working copy and allows you to choose exactly what resources to commit. A directory will always be committed recursively. Unversioned resources will be deselected by default. In the **Commit** dialog box you can also enter a comment before sending your changes to the repository.

 **Update all(Ctrl + Shift + U (Command + Shift + U on macOS))**

Updates all resources from the working copy that have incoming changes. It performs a recursive update on the synchronized resources.

 **Commit all**

Commits all the resources with outgoing changes. It is disabled when **Incoming** mode is selected or the synchronization result does not contain resources with outgoing changes. It performs a recursive commit on the synchronized resources.

 **Revert (Ctrl + Shift + V (Command + Shift + V on macOS))**

Undoes all local changes for the selected resources. It does not contact the repository and the files are obtained from Apache Subversion™ pristine copy. It is available only for modified resources. See Revert your changes *(on page 2934)* for more information.

Edit conflict (Ctrl + E (Command + E on macOS))

Opens the **Compare** editor, allowing you to modify the content of the currently conflicting resources. For more information about editing conflicts, see Edit conflicts *(on page 2932)*.

 **Mark Resolved (Ctrl + Shift + R (Command + Shift + R on macOS))**

Instructs the Subversion system that you resolved a conflicting resource. For more information, see Merge conflicts *(on page 2935)*.

 **Mark as Merged (Ctrl + Shift + M (Command + Shift + M on macOS))**

Instructs the Subversion system that you resolved the pseudo-conflict by merging the changes and you want to commit the resource. Read the Merge conflicts *(on*

page 2935) section for more information about how you can solve the pseudo-conflicts.

Override and Update

Drops any outgoing change and replaces the local resource with the HEAD revision. This action is available on resources with outgoing changes, including conflicting ones. See the Revert your changes *(on page 2934)* section.

Override and Commit

Drops any incoming changes and sends your local version of the resource to the repository. This action is available on conflicting resources. For more information see Drop incoming modifications *(on page 2936)*.

Mark as copied

You can use this action to mark an item from the working copy as a copy of another item under *version control*, when the copy operation was performed outside of an SVN client. The **Mark as copied** action is available when you select two items (both the new item and source item), and it depends on the state of the source item.

Mark as moved

You can use this action to mark an item from the working copy as being moved from another location of the working copy, when the move operation was performed outside of an SVN client. The **Mark as moved** action is available when you select two items from different locations (both the new item and the source item that is usually reported as *missing*), and it depends on the state of the source item.

Mark as renamed

You can use this action to mark an item from the working copy as being renamed outside of an SVN client. The **Mark as renamed** action is available when you select two items from the same directory (both the new item and the source item that is usually reported as *missing*), and it depends on the state of the source item.

Add to "svn:ignore" (Ctrl + Alt + I (Command + Option + I on macOS))

Allows you to add files that should not participate in the *version control* operations inside your working copy. This action can only be performed on resources not under *version control*. It actually modifies the value of the `svn:ignore` property in the parent directory of the resource. Read more about this in the Ignore Resources Not Under Version Control *(on page 2922)* section.

 **Add to version control (Ctrl + Alt + V (Command + Option + V on macOS))**

Allows you to add resources that are not under *version control*. For further details, see Add Resources to Version Control *(on page 2920)* section.

Remove from version control

Schedules the selected items for deletion from repository upon the next commit. The items are not removed from the file system after committing.

Clean up (Ctrl + Shift + C (Command + Shift + C on macOS))

Performs a maintenance cleanup operation on the selected resources from the working copy. This operation removes the Subversion maintenance locks that were left behind. This is useful when you already know where the problem originated and want to fix it as quickly as possible. It is only active for resources under *version control*.

Expand All (Ctrl + Alt + X (Command + Option + X on macOS))

Displays all descendants of the selected folder. The same behavior is obtained by double-clicking a collapsed folder.

Collapse all (Ctrl + Alt + Z (Command + Option + Z on macOS))

Collapses all descendants of the selected folder. The same behavior is obtained by double-clicking an expanded folder.

Compare Menu

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Next Block of Changes (Ctrl + Period (Command + Period on macOS))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

> **Note:**
> A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on macOS))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on macOS))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on macOS))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Last Change (Ctrl + E (Command + E on macOS))

Jumps to the last change.

First Change (Ctrl + B (Command + B on macOS))

Jumps to the first change.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Show Word Level Details

Provides a word-level comparison of the selected change.

Show Character Level Details

Provides a character-level comparison of the selected change.

ormat and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on macOS))

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences.

Note:
When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Ignore Whitespaces

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces.

History Menu

Show History(Ctrl + H (Command + H on macOS))

Displays the history for an SVN resource at a given revision. The resource can be one selected from the **Repositories** view, **Working Copy** view, or from the **Affected**

Paths table from the **History** view, depending on which view was last focused when this action was invoked.

 **Show Annotation (Ctrl + Shift + A (Command + Shift + A on macOS))**

Opens the **Show Annotation** dialog box that computes the annotations for a file and displays them in the **Annotations** view *(on page 3012)*, along with the history of the file in the **History** view.

Repositories

This operation is available for any resource selected from view, **Working Copy** view, **History** view or **Directory Change Sets** view, depending on which view was last focused when this action was invoked.

 **Revision Graph (Ctrl + G (Command + G on macOS))**

This action allows you to see the graphical representation of a resource's history. For more details about a resource's revision graph see the section Revision Graph *(on page 3020)*. This operation is available for any resource selected in the **Repositories** view or **Working Copy** view.

Tools Menu

Share project

Allows you to share a new project *(on page 2914)* using an SVN repository. The local project is automatically converted into an SVN working copy.

Branch / Tag

Allows you to copy the selected resource from the **Repositories** view or **Working Copy** view to a branch or tag into the repository. To read more about this operation, see the section Creating a Branch / Tag *(on page 2945)*.

 **Merge (Ctrl + J (Command + J on macOS))**

Allows you to merge the changes made on one branch back into the trunk, or vice versa, using the selected resource from the working copy. To read more about this operation, see the section Merging *(on page 2947)*.

Switch (Ctrl + Alt + W (Command + Option + W on macOS))

Allows you to change the repository location of a working copy, or only of a versioned item of the working copy, within the same repository. It is available when the selected item of the working copy is a versioned resource, except for *external* items. To read more about this action, see the Switching the Repository Location *(on page 2964)* section.

Relocate

Allows you to change the base URL of the root folder of the working copy to a new URL when the base URL of the repository changed. For example, if the repository itself was moved to a different server. This operation is only available for the root

item of the working copy. To read more about this operation, see the Relocate a Working Copy *(on page 2966)* section.

Create patch (Ctrl + Alt + P (Command + Option + P on macOS))

Allows you to create a file containing all the differences between two resources, based on the `svn diff` command. To read more about creating patches, see the section about patches *(on page 2969)*.

Working copy format

This submenu contains the following two operations:

Upgrade

Upgrades the format of the currently loaded working copy to the newest one known by Syncro SVN Client. This allows you to benefit of all the new features of the client.

Downgrade

Downgrades the format of the currently loaded working copy to SVN 1.7 format. This is useful if you want to use older SVN clients with the current working copy, or, by mistake, you have upgraded the format of an older working copy to SVN 1.8.

> **Note:**
> SVN 1.7 working copies cannot be downgraded to older formats.

See the section Working Copy Format *(on page 2997)* to read more about this subject.

Options Menu

Preferences

Opens the **Preferences** dialog box.

Menu Shortcut Keys

Opens the **Menu Shortcut Keys** preferences page *(on page 303)*, where users can configure in one place the keyboard shortcuts available for menu items available in Syncro SVN Client.

Global Run-Time Configuration

Allows you to configure SVN general options, that should be used by all the SVN clients you may use:

- **Edit 'config' file** - In this file you can configure various SVN client-side behaviors.
- **Edit 'servers' file** - In this file you can configure various server-specific protocol parameters, including HTTP proxy information and HTTP timeout settings.

Export Options

Allows you to export the current options to an XML file.

Import Options

Allows you to import options you have previously exported.

Reset Options

Resets all your options to the default ones.

Reset Authentication

Resets the Subversion authentication information.

Window Menu

Show View

Allows you to select the view you want to bring to front.

Show Toolbar

Allows you to select the toolbar you want to be visible.

Enable flexible layout

Toggles between a fixed and a flexible layout. When the flexible layout is enabled, you can move and dock the internal views to adapt the application to various viewing conditions and personal requirements.

Reset Layout

Resets all the views to their default position.

Help Menu

Help (F1)

Opens the **Help** dialog box.

Use online help (selected by default)

If this option is selected, when you select **Help** or press **F1** while hovering over any part of the interface, Oxygen XML Editor attempts to open the help documentation in online mode. If this option is not selected or an internet connection fails, the help documentation is opened in offline mode.

Show Dynamic Help view

Displays the **Dynamic Help** view.

Report Problem

Opens a dialog box that allows you to write the description of a problem that was encountered while using the application.

Support Center

Opens the Support Center web page in a browser.

About

Opens the **About** dialog box.

SVN Main Toolbar

The toolbar of the Syncro SVN Client SVN Repositories window contains the following actions:

 **Check out**

Checks out a working copy from a repository. The repository URL and the working copy format must be specified.

 **Synchronize**

Synchronizes the current working copy with the repository.

 **Update All**

Updates all resources of the working copy that have an older revision that repository.

 **Commit All**

Commits all resources of working copy that have a newer version compared to that of the repository.

 **Refresh**

Refreshes the whole content of the current working copy from disk starting from the root folder. At the end of the operation, the modified files and folders that were not committed to repository yet, are displayed in the **Working Copy** view.

 **Compare**

The selected resource is compared with:

- The *BASE* revision, when the selected resource is:
  - Locally modified and the **All Files** view mode is currently selected (no matter if there are incoming changes).
  - Locally modified and there are no incoming changes when any other view mode is selected.

- The remote version of the same resource, when remote information is available after a **Synchronize** operation (only when one of **Modified**, **Incoming**, **Outgoing** and **Conflicts** view modes is selected).
- The working copy revision, when the selected resource is from the **History** view.

 **Show History**

Displays the history of the selected resource (from the **Working Copy** or **Repository** views) in the **History** view.

 **Show Annotation**

Displays the annotations of the selected resource. The selected resource can be in the **Working Copy** or the **History** views.

 **Revision Graph**

Displays the revision graph of the selected resource. The selected resource can be in the **Working Copy** or the **Repositories** views.

 **Enable/Disable flexible layout**

Toggles between a fixed and a flexible layout. When the flexible layout is enabled, you can move and dock the internal views to adapt the application to various viewing conditions and personal requirements.

Status Bar

The status bar of the Syncro SVN Client window displays important details of the current status of the application. This information is available only in the **Working Copy** view.

Figure 708. Status bar

The status bar is composed of the following areas:

- The path of the currently processed file from the current working copy (during an operation such as **Check out** or **Synchronize**) or the result of the last operation.
- The current status of the following working copy options:
  - Show ignored files ( ).
  - Show deleted files ( ).
  - Process `svn:externals` definitions ( ).

  The options for ignored and deleted files are switched on and off from the **Settings** menu *(on page 2996)* of the **Working Copy** panel:
- The format of the currently loaded working copy.

- The current numbers of incoming changes ( ), outgoing changes ( ) and conflicting changes ( ).
- A progress bar for the currently running SVN operation and a button ( ) that allows you to stop it.

Getting Started

This section explains the basic operations that can be done in Syncro SVN Client.

SVN Repository Location

This section explains how to add and edit the repository locations in Syncro SVN Client.

Add / Edit / Remove Repository Locations

Usually, team members do all of their work separately, in their own working copy, and then must share their work by committing their changes. This is done using an Apache Subversion™ repository. Oxygen XML Editor supports versions 1.4, 1.5, 1.6, 1.7, and 1.8 of the SVN repository format.

Before you can begin working with a Subversion repository, you must define a repository location in the **Repositories** view *(on page 2985)*.

To create a repository location, use the **New Repository Location** action that is available in the **Repository** menu, the **Repositories** view toolbar, and in the contextual menu. This action opens the **New Repository Location** dialog box, which prompts you for the URL of the repository *(on page 3025)* you want to connect to. You can also use peg revisions at the end of the URLs *(on page 3027)* (for example, `URL@rev1234`) to browse only that specific revision. No authentication information is requested at the time the location is defined. It is left to the Subversion client to request the user and password information when it is needed. The main benefit of allowing Subversion to manage your password is that it prompts you for a new password only when your password changes.

Once you enter the repository URL, Oxygen XML Editor tries to contact the server to get the content of the repository for displaying it in the **Repositories** view *(on page 2985)*. If the server does not respond in the timeout interval set in the preferences, an error is displayed. If you do not want to wait until the timeout expires, you can use the **Stop** button from the toolbar of the view.

To edit a repository location, use the **Edit Repository Location** action that is available in the **Repository** menu and in the contextual menu. This action opens the **Edit Repository Location** dialog box, which prompts you for the URL of the repository *(on page 3025)* you want to connect to. You can also use peg revisions at the end of the URLs *(on page 3027)* (for example, `URL@rev1234`) to browse only that specific revision.

To remove a repository location, use the **Remove Repository Location** action that is available in the **Repository** menu and in the contextual menu. A confirmation dialog box is displayed to make sure that you do not accidentally remove the wrong locations.

The order of the repositories can be changed in the **Repositories** view at any time with the **Up** arrow and **Down** arrow buttons on the toolbar of the view. For example, pressing the up arrow once moves the selected repository in the list up one position.

To set the reference revision number of an SVN repository use the **Change the Revision to Browse** action that is available in the **Repository** menu and in the contextual menu. The revision number of the repository is used for displaying the contents of the repository when it is viewed in the **Repositories** view *(on page 2985)*. Only the files and folders that were present in the repository at the moment when this revision number was generated in the repository are displayed as contents of the repository tree. Also, this revision number is used for all the operations executed directly from the **Repositories** view *(on page 2985)*.

Authentication

Five protocols are supported: *HTTP*, *HTTPS*, *SVN*, *SVN + SSH* and *FILE*. If the repository that you are trying to access is password protected, the **Enter authentication data** dialog box requests a user name and a password. If the **Store authentication data** checkbox is selected, the credentials are stored in the Apache Subversion™ default directory:

- Windows - `%HOME%\Application Data\Subversion\auth`. Example: `C:\Documents and Settings\John\Application Data\Subversion\auth`
- Linux and macOS - `$HOME/.subversion/auth`. Example: `/home/John/.subversion/auth`

There is one file for each server that you access. If you want to make Subversion forget your credentials, you can use the **Reset authentication** command from the **Options** menu. This causes Subversion to forget all your credentials. When you reset the authentication data, restart Oxygen XML Editor for the change to take effect.

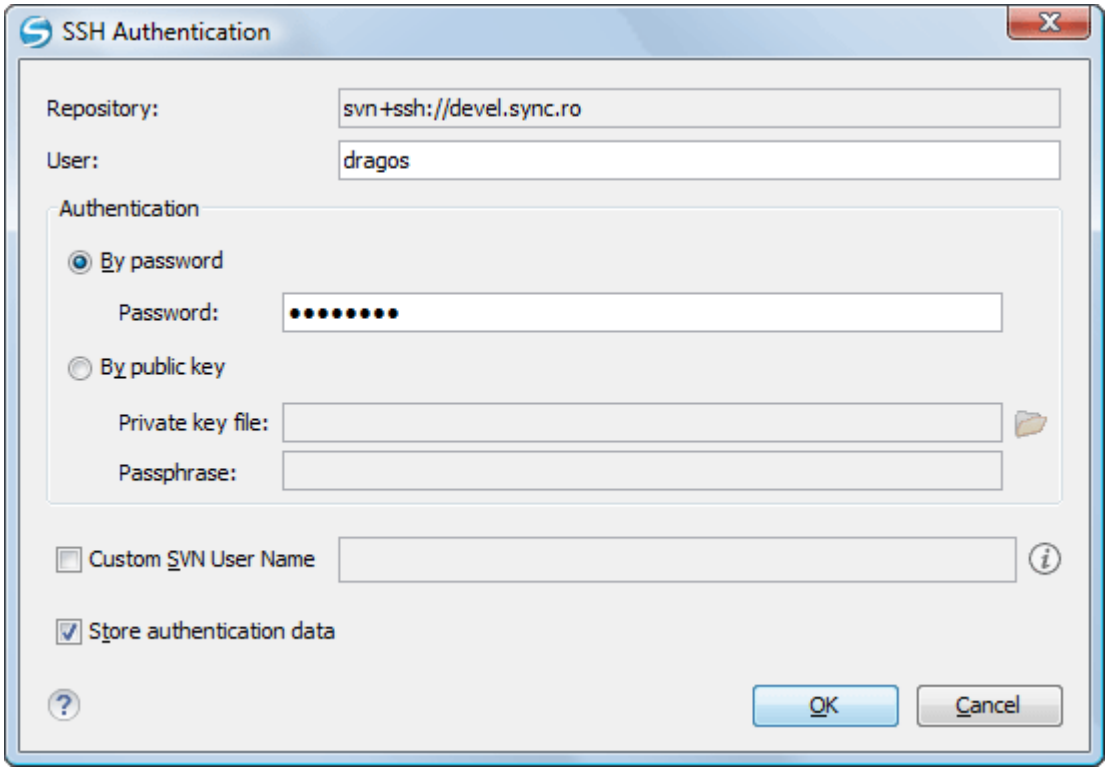
Tip:
The *FILE* protocol is recommended if the SVN repository and Oxygen XML Editor are located on the same computer as it ensures faster access to the SVN repository compared with other protocols.

For HTTPS connections where client authentication is required by your SSL server, you must choose the certificate file and enter the corresponding certificate password that is used to protect your certificate.

When using a secure HTTP (HTTPS) protocol for accessing a repository, a **Certificate Information** dialog box is displayed and asks you whether you want to accept the certificate permanently, temporarily, or simply deny it.

If the repository has SVN+SSH protocol, the SSH authentication can also be made with a private key and a pass phrase.

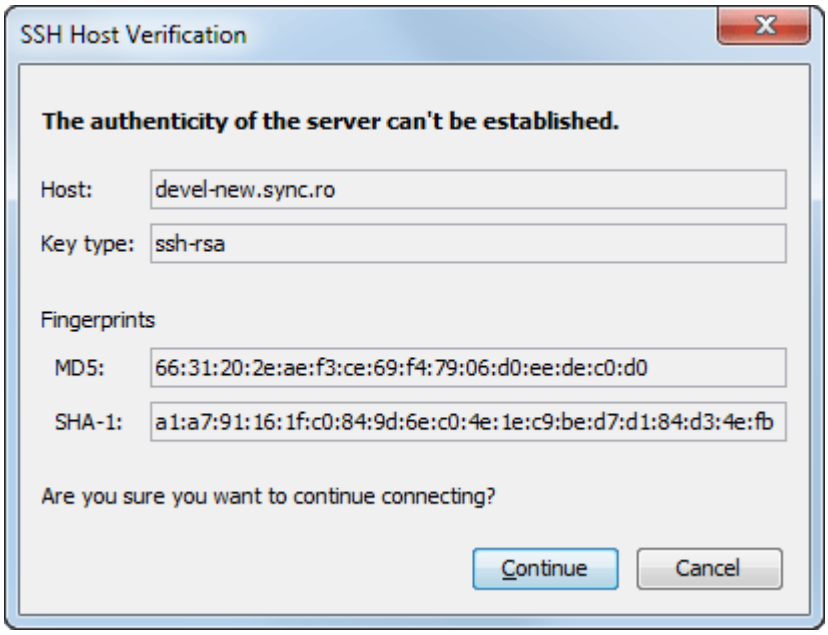
Figure 709. SSH Authentication Dialog Box



After the SSH authentication dialog box, another dialog box appears for entering the SVN user name that accesses the SVN repository. The SVN user name is recorded as the *committer* in SVN operations.

When connecting for the first time to a Subversion repository through SVN+SSH protocol, you will be asked to confirm if you trust the SSH host. The same dialog box is also displayed when the server changed the SSH key or when the key was deleted from the local Subversion cache folder.

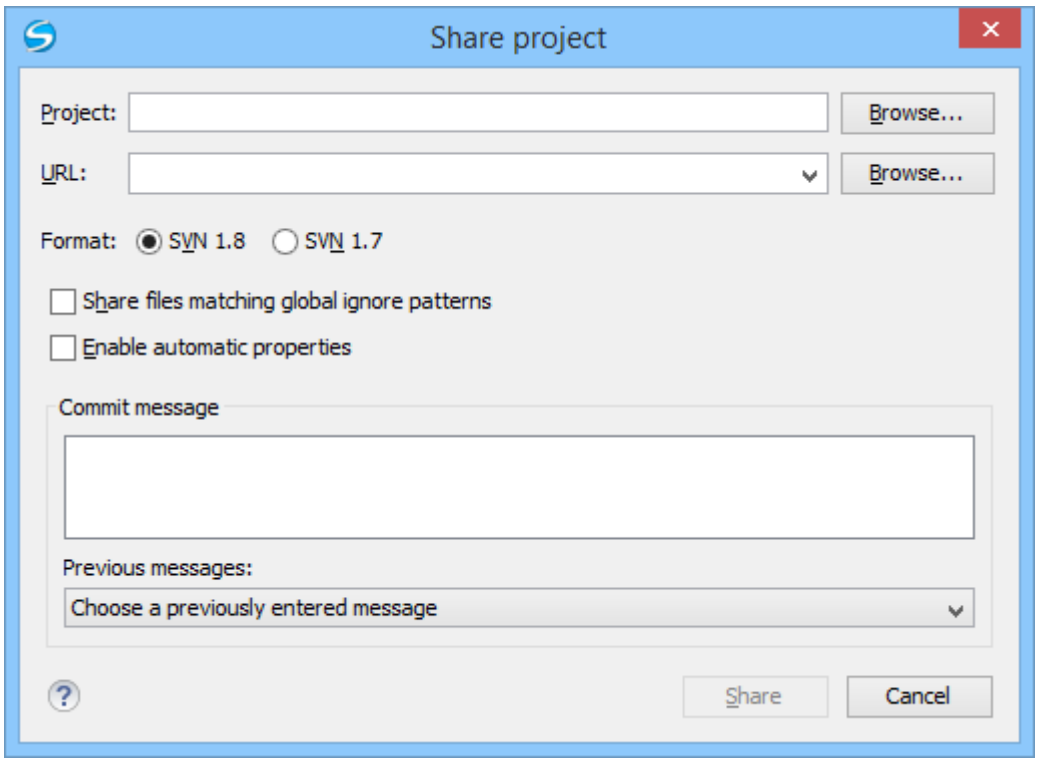
Figure 710. SSH server name and key fingerprint



Share a Project

Even if you start developing a new project, or you want to migrate an existing one to Subversion, the Syncro SVN Client allows you to easily share it with the rest of your team. The shared project directory is automatically converted to a working copy and added under Syncro SVN Client management. The **Share project** action is available in the **Tools** menu and the contextual menu of the **Repositories** view.

Figure 711. Share Project Dialog Box



The following options can be configured in the **Share project** dialog box:

Project

The location of the project folder *(on page 3025)* on the local disk by using the text box or the **Browse** button. This folder should not be empty or already under version control.

> **Important:**
> By default, the SVN system only imports the content of the specified folder, and not the root folder itself. Therefore, it is recommended to use the **Browse** button to select the project folder so that the client will automatically append the name of it to the specified URL.

URL

The new location of the project *(on page 3025)* (inside the repository) that will be used to access it.

Note:
Peg revisions have no effect for this operation since it is used to send information to the repository.

Attention:
If the new location already exists, make sure that it is an empty directory to avoid mixing your project content with other files (if items exist with the same name, an error will occur and the operation will not proceed). Otherwise, if the address does not exist, it is created automatically.

Format

The SVN format of the working copy. You can choose between **SVN 1.8** or **SVN 1.7**.

Share files matching global ignore patterns

When selected, the file names that match the patterns defined in either of the following locations are also imported into the repository:

- The `global-ignores` property in the SVN configuration file *(on page 3025)*.
- The **File name ignore patterns** option *(on page 293)* in the **SVN > Working Copy** preferences page *(on page 292)*.

Enable automatic properties/Disable automatic properties

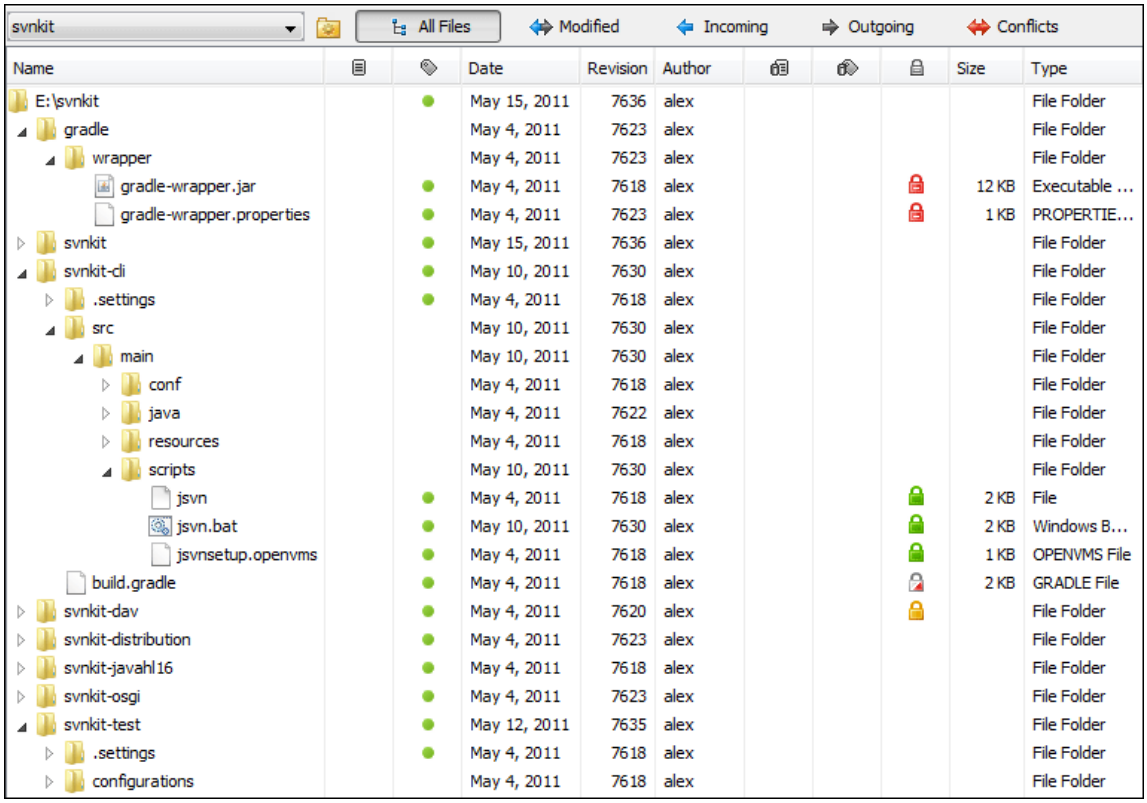
Enables or disables automatic property assignment (per runtime configuration rules), overriding the `enable-auto-props` runtime configuration directive, defined in the SVN configuration file *(on page 3025)*.

Note:
This option is available only when there are defined properties to be applied automatically for newly added items under version control. You can define these properties in the SVN `config` file (in the `auto-props` section). Based on the value of the `enable-auto-props` runtime configuration directive, the presented option is either **Enable automatic properties**, or **Disable automatic properties**.

Defining a Working Copy

An Apache Subversion™ working copy is an ordinary directory tree on your local system, containing a collection of files. You can edit these files however you want, your working copy being your private work area. To make your own changes available to others or incorporate changes made by others, you must explicitly tell Subversion to do so. You can even have multiple working copies of the same project.

Figure 712. Working Copy View



A Subversion working copy also contains some extra files, created and maintained by Subversion, to help it keep track of your files. In particular, each directory in your working copy contains a subdirectory named `.svn`, also known as the working copy *administrative directory*. This administrative directory contains an unaltered copy of the last updated files from the repository. This copy is usually referred to as the *pristine copy* or the *BASE revision* of the working copy. These files help Subversion recognize which files contain unpublished changes, and which files are out-of-date with respect to others' work.

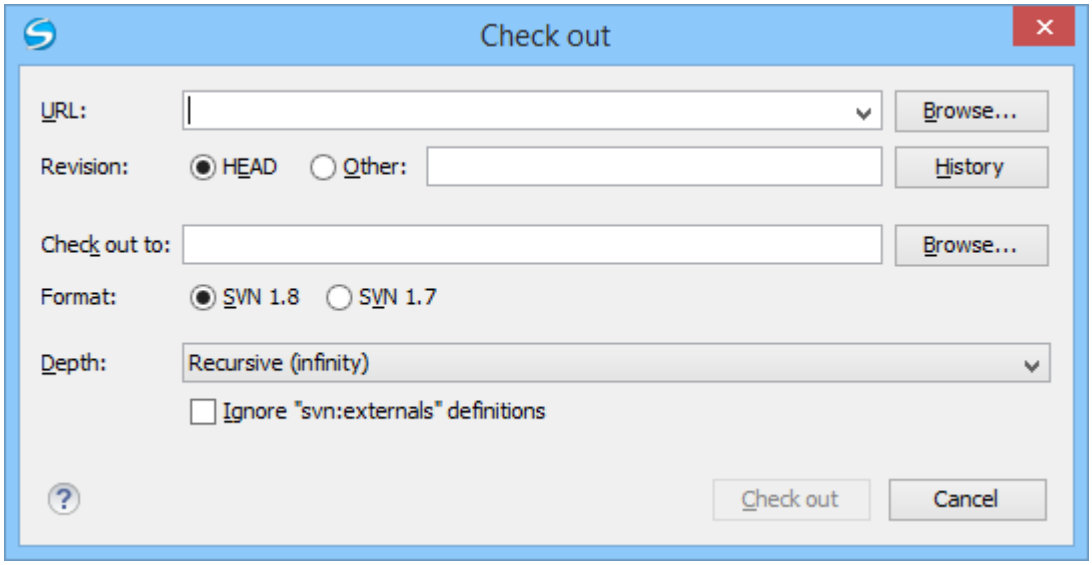
A typical Subversion repository often holds the files (or source code) for several projects. Usually each project is a subdirectory in the repository's file system tree. In this arrangement, a user's working copy usually corresponds to a particular sub-tree of the repository.

Check Out a Working Copy

Check out means to make a copy of a project from a repository to your local file system. This copy is called a *working copy*. An Apache Subversion™ working copy is a specially formatted directory structure that contains additional `.svn` directories that store Subversion information, as well as a pristine copy of each item that is checked out.

To check out a working copy, locate and select the desired directory in the **Repositories** view and select the **Check out** action from the contextual menu, the toolbar, or the **Repository** menu.

Figure 713. Check Out Dialog Box



The following options can be configured in the **Check out** dialog box:

URL

The location of the repository directory *(on page 3025)* to be *checked out*.

> **Note:**
> To check out an item that was deleted, moved, or replaced, you need to specify the original URL (before the item was removed) and use a *peg* revision *(on page 3027)* at the end (for example, `URL@rev1234`).

Revision

You can choose between the **HEAD** or **Other** revision. If you need to *check out* a specific revision, specify it in the **Other** text box or use the **History** button and choose a revision from the **History** dialog box *(on page 2918)*.

Check out to

Specify the location where you want to *check out (on page 3025)* the new working copy by typing the local path in the text box or by using the **Browse** button. If the specified local path does not point to an existing directory, it will automatically be created.

> **Important:**
> By default, the SVN system only checks out the content of the directory specified by the URL, and not the directory itself. Therefore, it is recommended to use the **Browse** button to select the *check out* location so that the client will automatically append the name of the remote directory to the path of the selected directory.

Warning:
The destination directory should be empty. If files exist, they are skipped (left unchanged) by the *check out* operation and displayed as *modified (on page 2992)* after the operation has finished. Also, the destination directory must not already be under version control.

Format

The SVN format of the working copy. You can choose between **SVN 1.8** or **SVN 1.7**.

Depth

The depth is useful if you want to *check out* only a part of the selected repository directory and bring the rest of the files and subdirectories in a future update. You can find out more about the checkout depth in the sparse checkouts *(on page 2984)* section. You can choose between the following depths:

- **Recursive (infinity)** - Checks out all the files and folders contained in the selected folder.
- **Immediate children (immediates)** - Checks out only the child files and folders without recursing subfolders.
- **File children only (files)** - Checks out only the child files.
- **This folder only (empty)** - Checks out only the selected folder (no child file or folder is included).

Ignore "svn:externals" definitions

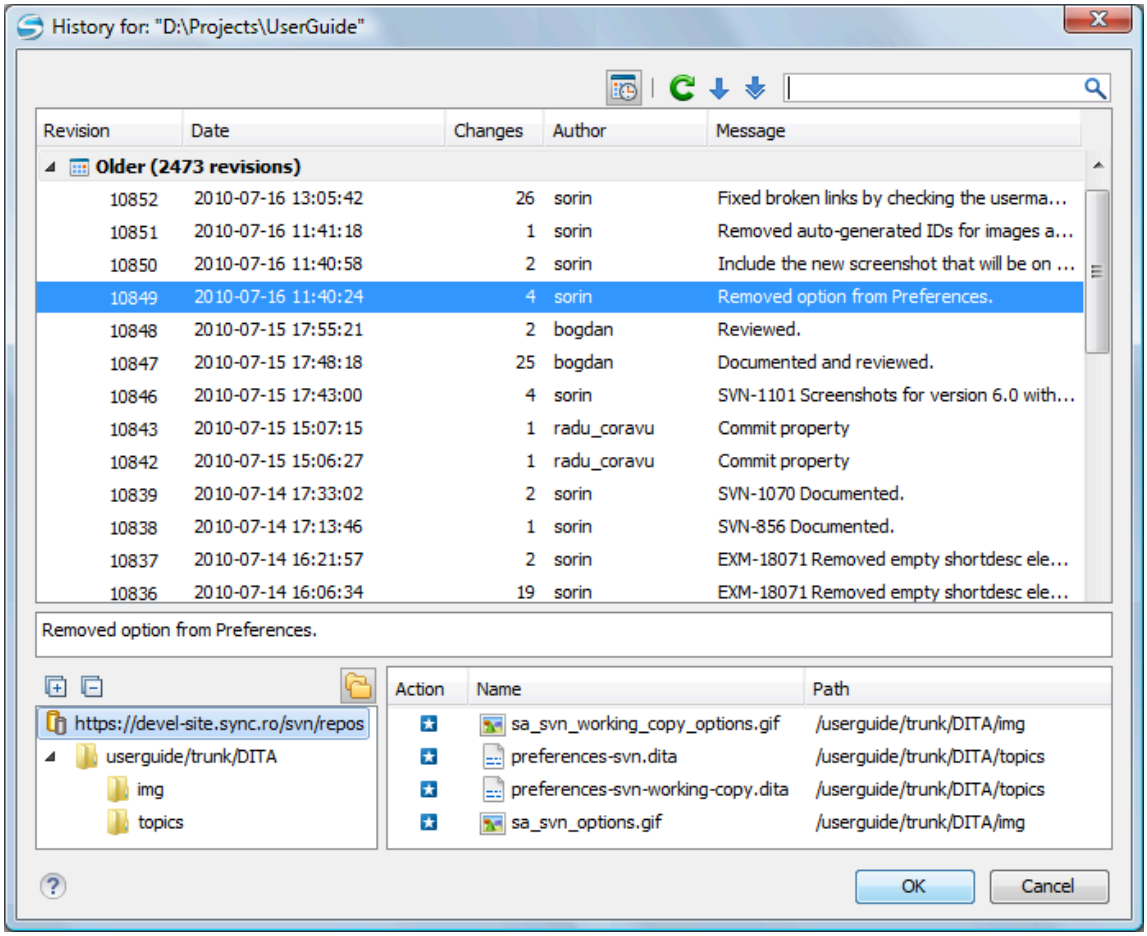
When selected, external items are ignored in the *check out* operation. This option is only available if you choose the **Recursive (infinity)** depth.

After a *check out*, the new working copy is added to the list in the **Working Copy** view *(on page 2990)* and loaded automatically.

History Dialog Box

The **History** dialog box presents a list of revisions for a resource. It is opened from the dialog boxes that require setting an SVN revision number, such as the **Check Out** dialog box *(on page 2916)* or the **Branch / Tag** dialog box *(on page 2945)*. It presents information about revision, commit date, author, and commit comment.

Figure 714. History Dialog Box



The initial number of entries in the list is 50. Additional revisions can be added to the list using the **Get next 50** and **Get all** buttons. The list of revisions can be refreshed at any time with the **Refresh** button. You can group revisions in predefined time frames (today, yesterday, this week, this month), by pressing the **Group by date** button from the toolbar.

The **Affected Paths** area displays all paths affected by the commit of the revision selected in history. You can see the changes between the selected revision and the file's previous state using the **Compare with previous version** action, available in the contextual menu.

Use an Existing Working Copy

Using an existing working copy is the process of taking a working copy that exists on your file system and connecting it to the Apache Subversion™ repository. If you have a brand new project that you want to import into your repository, then see the section Import resources into the repository *(on page 2979)*. The following procedure assumes that you have an existing valid working copy on your file system.

1. Click the **Working Copies Manager** toolbar button (on macOS) in the **Working Copy** view *(on page 2990)*.

   Step Result: This action opens the **Working copies list** dialog box.

2. Click the **Add** button.

3. Select the working folder copy from the file system. The name is useful to differentiate between working copies located in folders with the same name. The default name is the name of the root folder of the working copy.

   > **Note:**
   > For SVN 1.7 and newer working copies, all the internal information is kept only in the root directory. Thus, Syncro SVN Client needs to load the whole working copy.

4. Click the **OK** button.

The selected working copy is loaded and presented in the **Working Copy** view *(on page 2990)*.

> **Notice:**
> You can add working copies older than SVN 1.7. However, to load any of them, Syncro SVN Client will require to upgrade the working copy to SVN 1.8 format.

Manage Working Copy Resources

This section explains how to work with the resources that are displayed in the **Working Copy** view.

Edit Files

You can edit files from the **Working Copy** view *(on page 2990)* by double clicking them or by right clicking them and choosing **Open** from the contextual menu.

Note that only one file can be edited at a time. If you try to open another file, it is opened in the same editor window. The editor has syntax highlighting for known file types, meaning that a different color is used for each type of recognized token in the file. If the selected file is an image, then it is previewed in the editor, with no access to modifying it.

After modifying and saving a file from a working copy, a modified marker - an asterisk (*) - will be added to the file's icon in the **Working Copy** view *(on page 2990)*. The asterisk marks the files that have local modifications that were not committed to the repository.

Add Resources to Version Control

To share new files and folders (created in your working copy), add them to version control using the **Add to version control** option from the **Working Copy** view *(on page 2990)*.

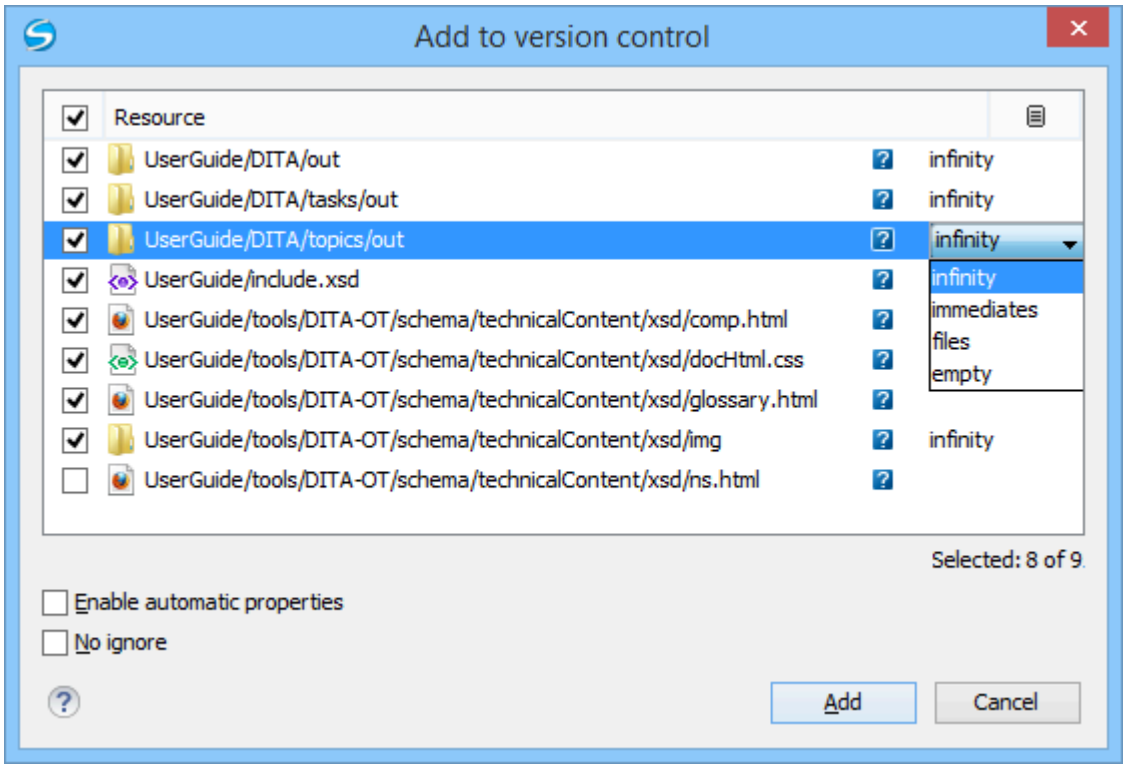
You can easily spot resources not under version control by the *unversioned* (?) icon displayed in the **Local file status** column. Resources scheduled for addition are displayed with this *added* (+) icon in the **Working Copy** view and are added in the repository after you commit them.

Note:
Do not make a confusion between and icons. The former icon stands for resources that are actually copies of resources already committed in the repository, meaning they are *scheduled for addition with history*.

When you use the **Add to version control** option on a directory, its entire structure is scanned and all the resources that can be added under version control are presented.

Although it is not mandatory to add resources under version control explicitly, it is recommended. If you forgot to add a resource, when you commit your changes *(on page 2938)*, the resource is presented in the commit dialog box, but not selected. When you commit and *unversioned* resource, it is automatically added under version control before starting the commit operation.

Figure 715. Add to Version Control Dialog Box



Note:
Ignored ( ) items can also be added under version control.

The **Depth** column is displayed only when directories are also presented in the dialog box. For any directory, you can use one of the available values to instruct Subversion to limit the scope of the operation to a particular tree depth.

Note:
The initial value of the **Depth** field can have the following values, depending on the listing mode of the items in the working copy view *(on page 2996)*:

- *infinity* - When the working copy items are presented as a tree.
- *files* - When the working copy items are presented compressed.
- *empty* - When the working copy items are presented flat.

When you add unversioned or ignored directories, the initial value of the **Depth** field also depends on the state of the **Show unversioned directories content** and **Show ignored directories content** options. If these options are selected, the value is based on the listing mode of the items in the working copy view. When they are not selected, the value is *empty*.

The following options are available in this dialog box:

- **Enable automatic properties** or **Disable automatic properties** - enables or disables automatic property assignment (per runtime configuration rules), overriding the `enable-auto-props` runtime configuration directive, defined in the `config` file of the Subversion configuration directory.

  Note:
  This option is available only when there are defined properties to be applied automatically for resources newly added under version control. You can define these properties in the `config` file of the Subversion configuration directory, in the `auto-props` section. Based on the value of the `enable-auto-props` runtime configuration directive, the presented option is either **Enable automatic properties**, or **Disable automatic properties**.

- **No ignore** - when you select this option, file-name patterns defined to ignore *unversioned* resources do not apply. Resources that are located inside an *unversioned* directory selected for addition, and match these patterns, are also scheduled for addition in the repository.

  Note:
  This option is available only when directories are also presented in the dialog box.

  You can define file-name patterns to ignore *unversioned* resources in one of the following locations:
  - In the `config` file of the Subversion configuration directory (the `global-ignores` option from the `miscellany` section).
  - In the Oxygen XML Editor options (open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **SVN > Working copy > Application global ignores**).

Each of the above two options is activated only when you select an item that can have the option applied.

Ignore Resources Not Under Version Control

Some resources inside your working copy do not need to be subject to version control. These resources can be files created by the compiler, `*.obj`, `*.class`, `*.lst`, or output folders used to store temporary

files. Whenever you commit changes *(on page 2938)*, Apache Subversion™ shows your modified files in the commit dialog box, but the unversioned files are also listed. Since the unversioned files are committed unless otherwise specified, it is difficult to see exactly what you are committing.

The best way to avoid these problems is to add the derived files to the Subversion ignore list. That way they are never displayed in the commit dialog box and only genuine unversioned files that must be committed are displayed.

You can choose to ignore a resource by using the **Add to svn:ignore** action in the contextual menu of the **Working Copy** view *(on page 2990)*.

In the **Add to svn:ignore** dialog box, you can specify the resource to be ignored by name or by a custom pattern. The custom pattern can contain the following wildcard characters:

- * - Matches any string of characters of any size, including the empty string.
- ? - Matches any single character.

For example, you can choose to ignore all text documents by using the pattern: `*.txt`.

The action **Add to svn:ignore** adds a predefined Subversion property called `svn:ignore` to the parent directory of the specified resource. In this property, there are specified all the child resources of that directory that must be ignored. The result is visible in the **Working Copy** view. The ignored resources are represented with gray icons.

Delete Resources

The **Delete** action is available in the contextual menu of the **Working Copy** view *(on page 2990)*. When you delete an item from the working copy, it is marked as *deleted* (scheduled for deletion from repository upon the next commit) and removed from the file system. Depending on the state of each item, you are prompted to confirm the operation.

If a resource is deleted from the file system without Subversion's knowledge, the resource is marked as *missing* ( ) in your working copy. You can decide what you want to do with a *missing* item:

- In the case of a commit, any *missing* item is first automatically deleted and then committed.

  Note:
  Not any *missing* item can be committed as *deleted*, and removed from the repository. For example, you cannot commit an item that no longer exists on the disk and that was scheduled for addition ( ) previously, since this item does not exist in the repository, but you can use the **Delete** action instead.

- If you want to recover *missing* items, either update *(on page 2937)* the items themselves or one of their parent directories. This fetches their latest version from the repository.

You can also delete conflicting items (file content conflicts, property conflicts, tree-conflicts) and Syncro SVN Client automatically marks them as resolved.

Note:
It is recommended that you resolve conflicts manually to avoid loosing any important remote modifications.

Finally, you can change your mind and revert *(on page 2934)* the deleted items to their initial, pristine, state.

Copy Resources

You can copy resources from various locations of the working copy. You select them in the **Working Copy** view *(on page 2990)* and then use **Copy to** from the contextual menu. This is not a simple file system copy, but an Apache Subversion™ command. It will copy the resource and the copy will also have the original history. This is one of the important features of Subversion, as you can keep track of where the copied resources originated.

Based on the selected items, the **Copy to** action is available only if it can be performed. Even if the operation would not normally be possible in SVN (due to some invalid local file states against copy), Oxygen XML Editor performs the copy operation as a simple file system operation. This means no SVN versioning meta-data is affected.

Note:

- If you copy an item to a directory that is not under version control *(on page 2992)* (*unversioned* or *ignored*), the history of the item is not preserved. For example, when copying directories, all items inside them will also be copied without history.
- If you copy a directory that contains *external (on page 2992)* items, these are not copied. This is specific for SVN 1.7 working copies only. To fetch the *external* items, use the **Update** operation on the copied directory.

In the **Copy to** dialog box, you can navigate through the working copy directories to choose a target directory, to copy inside it. If you try to copy a single resource you are also able to change that resource's name. For *versioned* items, you can select **Ignore resource history** to copy them without their history (similar to a simple file system copy).

Note:
The **Copy to** dialog box only presents all the local directories that are a valid destination against the copy operation, based on their local file status. Also, the working copy settings *(on page 2996)* are taken into account.

In the **Commit** dialog box, only the directory in question will appear without its children.

Move Resources

As in the case of the copy command, you can move several resources at once. Select the resources in the **Working Copy** view *(on page 2990)* and choose the **Move to** action from the contextual menu. The move command actually behaves as if a copy followed by a delete command were issued. You will find the moved resources at the desired destination and also at their original location, but marked as *deleted*.

Note:
External items cannot be moved using the **Move to** action, because they cannot be deleted. Instead, you should edit the `svn:externals` property defining the *external* item and use the **Update** operation on the item's parent folder for the change to take effect.

Attention:
For SVN 1.8 working copies: when committing items that were moved and/or renamed, make sure you select both the source and the destination. Otherwise, the commit operation will fail.

Rename Resources

The **Rename** action is available in the contextual menu of the **Working Copy** view *(on page 2990)* and can be performed on a single resource. This action acts as a move command with the destination directory being the same as the original location of the resource. A copy of the original item is created with the new name, also keeping its history. The original item is marked as *deleted*.

Note:
External items cannot be renamed using the **Rename** action because they cannot be deleted. Instead, you should edit the *svn:externals* property defining the *external* item, then use the **Update** operation on the item's parent folder for the change to take effect.

Attention:
For SVN 1.8 working copies: when committing items that were moved and/or renamed, make sure you select both the source and the destination. Otherwise, the commit operation will fail.

Lock / Unlock Resources

The idea of version control is based on the *copy-modify-merge* model of file sharing. This model states that each user contacts the repository and creates a local working copy (check out). Users can then work independently and modify their working copies according to their needs. When their goal has been accomplished, it is time for the users to share their work with the others, to send them to the repository (commit). When a user has modified a file that has been also modified on the repository, the two files will have to be merged. The version control system assists the user with the merging as much as it can, but in the end the user is the one that must make sure it is done correctly.

The copy-modify-merge model only works when files are contextually mergeable: this is usually the case of line-based text files (such as source code). However this is not always possible with binary formats, such as images or sounds. In these situations, the users must each have exclusive access to the file, ending up with a *lock-modify-unlock* model. Without this, one or more users could end up wasting time on changes that cannot be merged.

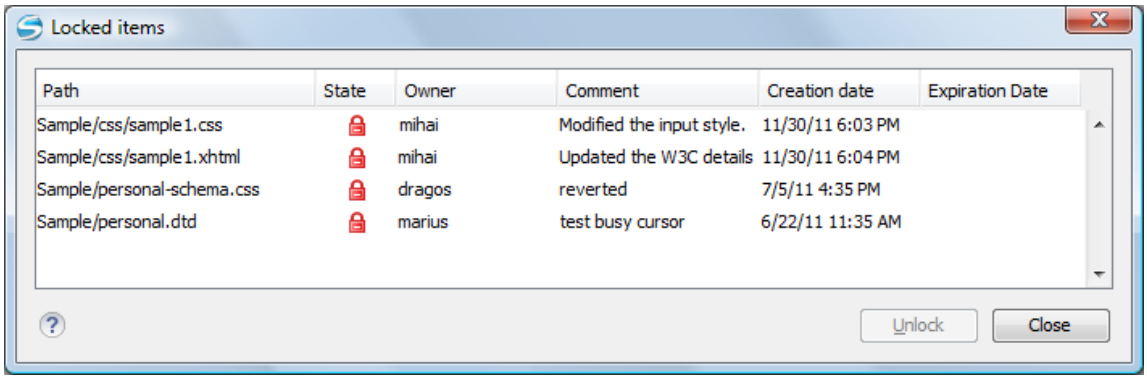
An SVN lock is a piece of metadata that grants exclusive access to a user. This user is called the lock owner. A lock is uniquely identified by a lock token (a string of characters). If someone else attempts to commit the file (or delete a parent of the file), the repository demands two pieces of information:

- User authentication - the user performing the commit must be the lock owner
- Software authorization - the user's working copy must have the same lock token as the one from the repository, proving that it is the same working copy where the lock originated from.

Scanning for Locks

When starting to work on a file that is not contextually mergeable (usually a binary file), it is better to verify if someone else is not already working on that file. You can do this in the **Working Copy** view *(on page 2990)* by selecting one or more resources, then right-clicking them and choosing the **Scan for Locks** action from the contextual menu.

Figure 716. Locked Items Dialog Box



The **Locked items** dialog box contains a table with all the resources that were found locked on the repository. For each resource there are specified: resource path, state of the lock, owner of the lock, lock comment, creation and expiration date for the lock (if any).

The state of the lock can be one of the following:

- - Appears when one of the following conditions apply:
  - Another user has locked the file in the repository.
  - The file was locked by the same user from another working copy.
  - The file was locked from the **Repositories** view.
- - Displayed after you have locked a file from the current working copy.

- - A file already locked from your working copy is no longer locked in the repository (it was unlocked by another user).
- - A file already locked from your working copy is being locked by another user. Now the owner of the file lock is the user who stole the lock from you.

You can unlock a resource by selecting it and pressing the **Unlock** button.

Related Information:
Working Copy Locks *(on page 2994)*
Repository Locks *(on page 2985)*

Locking a File

By locking a file, you have exclusive write access to it in the repository.

You can lock a file from your working copy or directly from the **Repositories** view.

Note:
You can only lock files (not directories). This is a restriction imposed by Apache Subversion™.

The **Lock** dialog box allows you to write a comment when you set a lock or when you *steal* an existing one. Note that you should *steal* a lock only after you made sure that the previous owner no longer needs it. Otherwise, you may cause an unsolvable conflict, which could be the reason the lock was put there in the first place. The Subversion server can have a policy concerning lock stealing, as it may not allow you to do this if certain conditions are not met.

The lock stays in place until you unlock the file or until someone breaks it. There is also the possibility that the lock expires after a period of time specified in the Subversion server policy.

Unlocking a File

A file can be unlocked from the contextual menu of the **Working Copy** view *(on page 2990)*. A dialog box will prompt you to confirm the unlocking and it will also allow you to break the lock (unlock it by force).

Synchronize with Repository

In the work cycle you will need to incorporate other people's changes (update) and to make your own work available to others (commit). This is what the **Incoming** and **Outgoing** modes of the **Working Copy** view *(on page 2990)* was designed for, to help you send and receive modifications from the repository.

The **Incoming** and **Outgoing** modes of this view focus on incoming and outgoing changes. The incoming changes are the changes that other users have committed in the repository since you last updated your working copy. The outgoing changes are the modifications you made to your working copy as a result of editing, removing or adding resources.

The view presents the status of the working copy resources against the BASE revision after a **Refresh** operation. You can view the state of the resources versus a repository HEAD revision by using the **Synchronize** action from the **Working Copy** view *(on page 2990)*.

View Differences

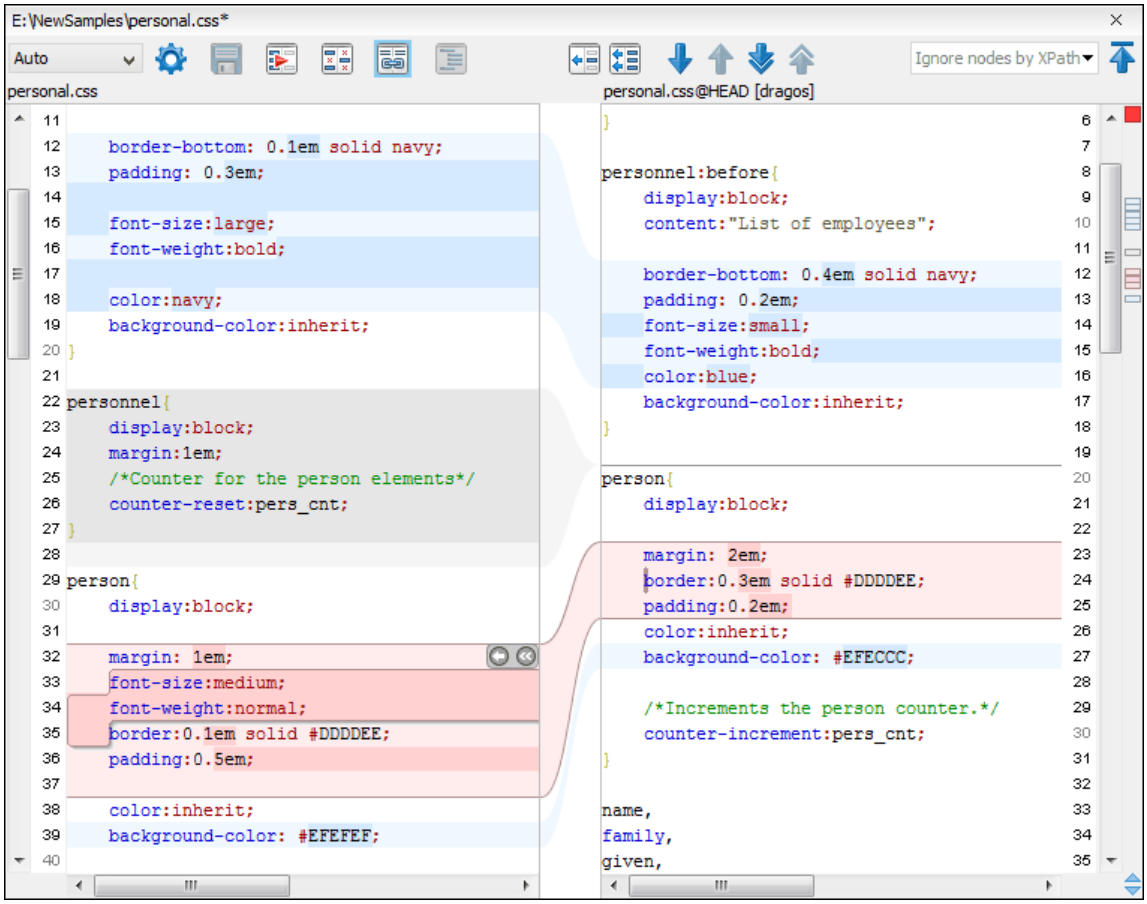
One of the most common requirements in project development is to see what changes have been made to the files from your Working Copy or to the files from the repository. You can examine these changes after a synchronize operation with the repository, by using the **Open in compare editor** action from the contextual menu.

The text files are compared using a built-in **Compare** view *(on page 3014)* that uses a line differencing algorithm or a specified external diff application (if such an application is set in the **SVN Diff** preferences page *(on page 293)*). When a file with outgoing status is involved, the compare is performed between the file from the working copy and the BASE revision of the file. When a file with incoming or conflict status is involved, the differences are computed using a three-way algorithm that means that the local file and the repository file are each compared with the BASE revision of the file. The results are displayed in the same view. The differences obtained from the local file comparison are considered outgoing changes and the ones obtained from the repository file comparison are considered incoming changes. If any of the incoming changes overlap outgoing changes then they are in conflict.

A special case of difference is a *diff pseudo-conflict*. This is the case when the left and the right sections are identical but the BASE revision does not contain the changes in that section. By default, this type of changes are ignored. If you want to change this, you can go to the **SVN** preferences page and select the **Allow unversioned obstructions** option *(on page 291)*.

The right editor of the internal compare view presents either the BASE revision or a revision from the repository of the file so its content cannot be modified. By default, when opening a synchronized file in the **Compare** view, a compare is automatically performed. After modifying and saving the content of the local file presented in the left editor, another compare is performed. You will also see the new refreshed status in the **Working Copy** view *(on page 2990)*.

Figure 717. Compare View



At the top of each of the two editors, there are presented the name of the open file, the corresponding SVN revision number (for remote resources) and the author who committed the associated revision.

There are three types of differences:

- Incoming changes - Changes committed by other users and not present yet in your working copy file. They are marked with a blue highlight and on the middle divider the arrows point from right to left.
- Outgoing changes - Changes you have done in the content of the working copy file. They are marked with a gray highlight and the arrows on the divider are pointing from left to right.
- Conflicting changes - This is the case when the same section of text that you already modified in the local file has been modified and committed by some other person. They are marked with a red highlight and red diamonds on the divider.

There are numerous actions and options available in the **Compare View** toolbar *(on page 3015)* or in the **Compare** menu from the main menu. You can decide that some changes need adjusting or that new ones must be made. After you perform the adjustments, you may want to perform a new compare between the files. For this case there is an action called **Perform files differencing**. After each files differencing operation the first found change will be selected. You can navigate from one change to another by using the actions **Go to first**, **Go to previous**, **Go to next** and **Go to last modification**. If you decide that some incoming change needs to be present in your working file you can use the action **Copy change from right to left**. This is useful also when you want to override the outgoing modifications contained in a conflicting section. The **Copy all**

non-conflicting changes from right to left action copies all incoming changes that are not contained inside a conflicting section in your local file.

Suppose that only a few words or letters are changed. Considering that the differences are performed taking whole lines of text into account, the change will contain all the lines involved. To find exactly what words or letters have changed, the **Word Details** and **Character Details** dialog boxes are available. They present a more detailed comparison result when you double-click the middle divider of a difference.

When you want to examine only the changes in the real text content of the files, while disregarding the changes in the number of white spaces between words or lines, there is an option available in the SVN Preferences *(on page 290)* that allows you to enable or disable the white space ignoring feature of the compare algorithm.

Conflicts

A file conflict occurs when two or more developers have changed the same few lines of a file or the properties of the same file. As Subversion knows nothing of your project, it leaves resolving the conflicts to the developers. Whenever a conflict is reported, you should open the file in question, and try to analyze and resolve the conflicting situation.

Real Conflicts vs Mergeable Conflicts

There are two types of conflicts:

- *real conflict* (icon in *Name* column) - Syncro SVN Client considers the following resource states to be real conflicts:
  - *conflicted* state - A file reported by SVN as being in this state is obtained after it was updated/ merged while having incoming and outgoing content or property changes at the same time, changes that could not be merged. A content conflict (icon in *Local file status* column) is reported when the modified file has binary content or it is a text file and both local and remote changes were found on the same line. A properties conflict (icon in *Local properties status* column) is reported when a property's value was modified both locally and remotely.
  - *tree conflicted* state (icon in *Local file status* column) - Obtained after an update or merge operation, while having changes at the directory structure level (for example, file is locally modified and remotely deleted or locally scheduled for deletion and remotely modified).
  - *obstructed* state (icon in *Local file status* column) - Obtained after a resource was versioned as one kind of object (file, directory, symbolic link), but has been replaced outside Syncro SVN Client by a different kind of object.
- *pseudo-conflict* (icon in *Name* column) - A file is considered to be in *pseudo-conflict* when it contains both incoming and outgoing changes. When incoming and outgoing changes do not intersect, an update operation may automatically merge the incoming file content into the existing locally one. In this case, the *pseudo-conflict* marker is removed. This marker is used only as a warning that should prevent you to run into a real conflict.

Note:

- A conflicting resource cannot be committed to repository. You have to resolve it first, by using **Mark Resolved** action (after manually editing/merging file contents) or by using **Mark as Merged** action (for pseudo-conflicts).
-  and  icons are presented only when one of the following view modes is selected: **Modified**, **Incoming**, **Outgoing**, **Conflicts**.
- The  icon is used also for folders to signal that they contain a file in real conflict or pseudo-conflict state.

Content Conflicts vs Property Conflicts

A *Content conflict* appears in the content of a file. A merge occurs for every inbound change to a file that is also modified in the working copy. In some cases, if the local change and the incoming change intersect each other, Apache Subversion™ cannot merge these changes without intervention. So if the conflict is real when updating the file in question the conflicting area is marked like this:

```
<<<<<<< filename
your changes
=====
code merged from repository
>>>>>>> revision
```

Also, for every conflicted file Subversion places three additional temporary files in your directory:

- `filename.ext.mine` - This is your file as it existed in your working copy before you updated your working copy, that is without conflict markers. This file has your latest changes in it and nothing else.
- `filename.ext.rOLDREV` - This is the file that was the BASE revision before you updated your working copy, that is the file revision that you updated before you made your latest edits.
- `filename.ext.rNEWREV` - This is the file that Subversion client just received from the server when you updated your working copy. This file corresponds to the HEAD revision of the repository.

OLDREV and NEWREV are revision numbers. If you have conflicts with binary files, Subversion does not attempt to merge the files by itself. The local file remains unchanged (exactly as you last changed it) and you will get `filename.ext.r*` files also.

A *Property conflict* is obtained when two people modify the same property of the same file or folder. When updating such a resource a file named `filename.ext.prej` is created in your working copy containing the nature of the conflict. Your local file property that is in conflict will not be changed. After resolving the conflict, you should use the **Mark resolved** action to commit the file. Note that the **Mark resolved** action does not really resolve the conflict. It just removes the conflicted flag of the file and deletes the temporary files.

Edit Real Content Conflicts

The conflicts of a file in the conflicted state (a file with the red double arrow icon) can be edited visually with the **Compare** view (the built-in file comparison tool) or with an external diff application *(on page 290)*. Resolving the conflict means deciding for each conflict if the local version of the change will remain or the remote one instead of the special conflict markers inserted in the file by the SVN server.

The **Compare** view (or the external diff application set in Preferences *(on page 290)*) is opened with the **Edit Conflict** action, which is available on the contextual menus of the **Working Copy** view *(on page 2990)* for files in the conflicted state (an update operation was executed but the differences could not be merged without conflicts). The external diff application is called with 3 parameters because it is a 3-way diff operation between the local version of the file from the working copy and the HEAD version from the SVN repository with the BASE version from the working copy as common ancestor.

If the**Show warning dialog when edit conflicts** option *(on page 294)* is selected, you will be warned at the beginning of the operation that the operation will overwrite the conflict version of the file received from the SVN server (the version that contains the conflict markers <<<<<<<, =======, >>>>>>>) with the original local version of the file that preceded the update operation. If you click the OK button the visual conflict editing will proceed and a backup file of the conflict version received from the SVN server is created in the same working copy folder as the file with the edited conflicts. The name of the backup file is obtained by appending the extension `.sync.bak` to the file as stored on the SVN server. If you click the **Cancel** button the visual editing will be aborted.

The usual actions on the differences between two versions of a file are available on the toolbar of this view:

 **Save**

Saves the modifications of the local version of the file displayed in the left side of the view.

 **Perform Files Differencing**

Looks for differences between the two files displayed in the left and right side panels.

 **Ignore Whitespaces**

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces.

 **Synchronized scrolling**

Toggles synchronized scrolling. When toggled on, a selected difference can be seen in both panels.

 **Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on macOS))**

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences.

> **Note:**
> When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Next Block of Changes (Ctrl + Period (Command + Period on macOS))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

> **Note:**
> A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on macOS))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on macOS))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on macOS))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

First Change (Ctrl + B (Command + B on macOS))

Jumps to the first change.

The operation begins by overwriting the conflict version of the file received from the SVN server (the version that contains the conflict markers <<<<<<<, =======, >>>>>>>) with the original local version of the file before running the update action that created the conflict. After that the differences between this original local version and the repository version are displayed in the **Compare** view.

If you want to edit the conflict version of the file directly in a text editor instead of the visual editing offered by the **Compare** view you should work on the local working copy file after the update operation without running the action **Edit Conflict**. If you decide that you want to edit the conflict version directly after running the action **Edit Conflict** you have to work on the `.sync.bak` file.

If you did not finish editing the conflicts in a file at the first run of the action **Edit Conflict** you can run the action again and you will be prompted to choose between resuming the editing where the previous run left it and starting again from the conflict file received from the SVN server.

After the conflicts are edited and saved in the local version of the file you should run one of the following:

- The **Mark Resolved** action on the file so that the result of the conflict editing process can be committed to the SVN repository.
- The **Revert** action so that the repository version overwrites all the local modifications.

Both actions remove the backup file and other temporary files created with the conflict version of the local file.

Revert Your Changes

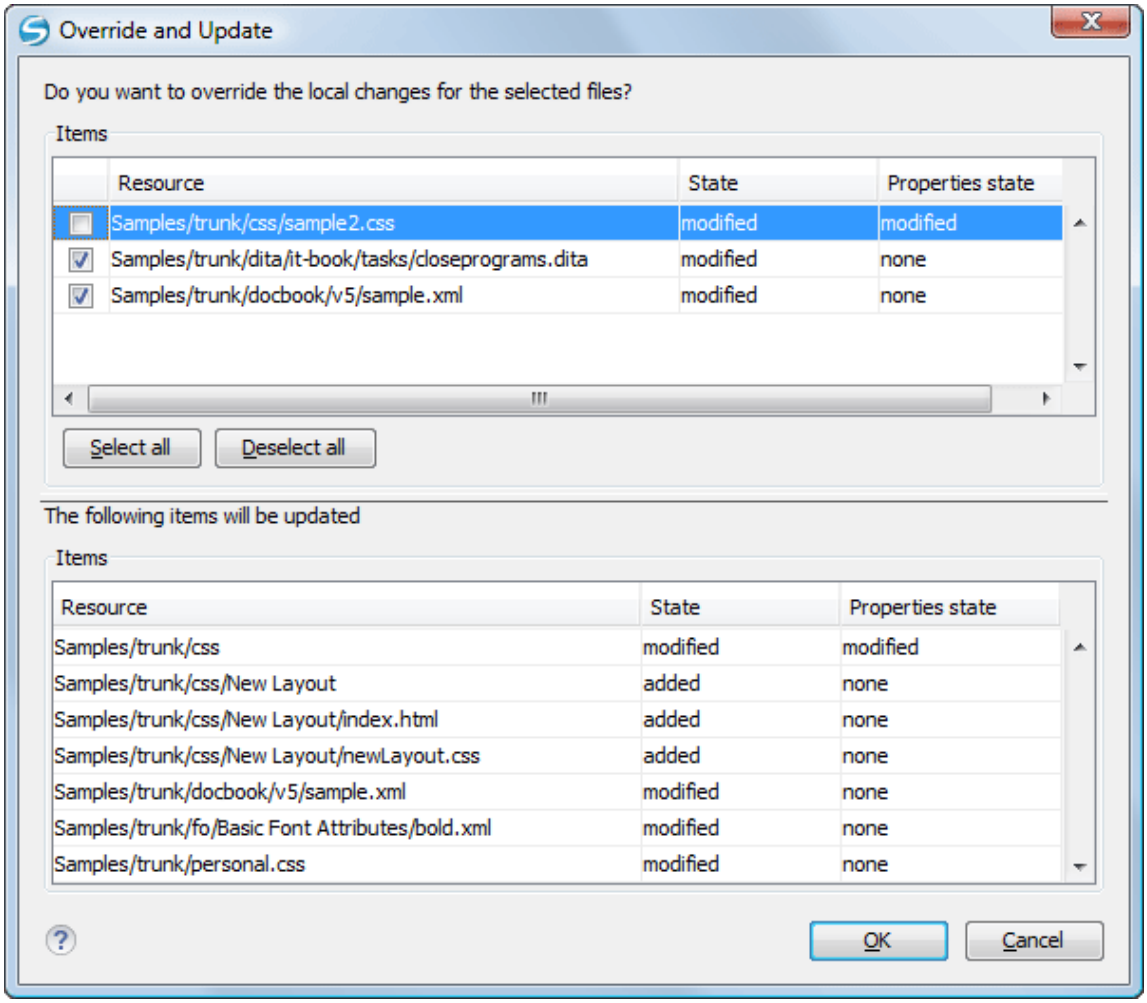
If you want to undo changes made in your working copy, since the last update, select the items you are interested in, right-click to display the contextual menu and select **Revert**. A dialog box will open that shows you the files and folders that you have changed and can be reverted. Select those you want to revert and click the **OK** button. Revert will undo only your local changes. It does not undo any changes that have already been committed. If you choose to revert a conflicting item to its pristine copy, then the eventual conflict is solved by losing your outgoing modifications. If you try to revert a resource not under version control, the resource will be deleted from the file system.

Note:
By default, a directory will be recursively reverted (including any other modified item it contains). However, if the directory has only property changes, you need to explicitly choose if the operation will include any modified items found inside it.

If you want some of your outgoing changes to be overridden you must first open the file in **Compare** view *(on page 3014)* and choose the sections to be replaced with ones from the repository file. This can be achieved either by editing directly the file or by using the action **Copy change from right to left** from the **Compare** view toolbar *(on page 3015)*. After editing the conflicting file you have to run the action **Mark as merged** before committing it.

If you want to drop all local changes and bring all incoming changes into your working copy resource, you can use the **Override and update** action. It discards the changes in the local file and updates it from the repository. A dialog box will display the files that will be affected.

Figure 718. Override and Update Dialog Box



In the first table of the dialog box you will be able to see the resources that will be overridden. In the second table you will find the list of resources that will be updated. Only resources that have an incoming status are updated.

Tip:
If you want to roll-back out of your working copy changes that have already been committed to the repository, see Merge Revisions *(on page 2952)*.

Merge Conflicted Resources

Before you can safely commit your changes to the repository you must first resolve all conflicts. In the case of pseudo-conflicts they can be resolved in most cases with an update operation that will merge the incoming modifications into your working copy resource. In the case of real conflicts, conflicts that persist after an update operation, it is necessary to resolve the conflict using the built-in compare view and editor or, in the case of properties conflict, the **Properties** view *(on page 3018)*. Before you can commit you must *mark as resolved* the affected files.

Both pseudo and real conflicts can be resolved without an update. You should open the file in the compare editor and decide which incoming changes need to be copied locally and which outgoing changes must

be overridden or modified. After saving your local file you have to use the *Mark as merged* action from the contextual menu before committing.

Drop Incoming Modifications

In the situation when your file is in conflict but you decide that your working copy file and its content is the correct one, you can decide to drop some or all of the incoming changes and commit afterwards. The action **Mark as merged** proves to be useful in this case too. After opening the conflicting files with **Compare** view *(on page 3014)*, Editor *(on page 3011)* or editing their properties in the **Properties** view and deciding that your file can be committed in the repository replacing the existing one, you should use the **Mark as merged** action. When you want to override completely the remote file with the local file you should run the **Override and commit** action, which drops any remote changes and commits your file.

In general it is much safer to analyze all incoming and outgoing changes using the **Compare** view and only after to update and commit.

Tree Conflicts

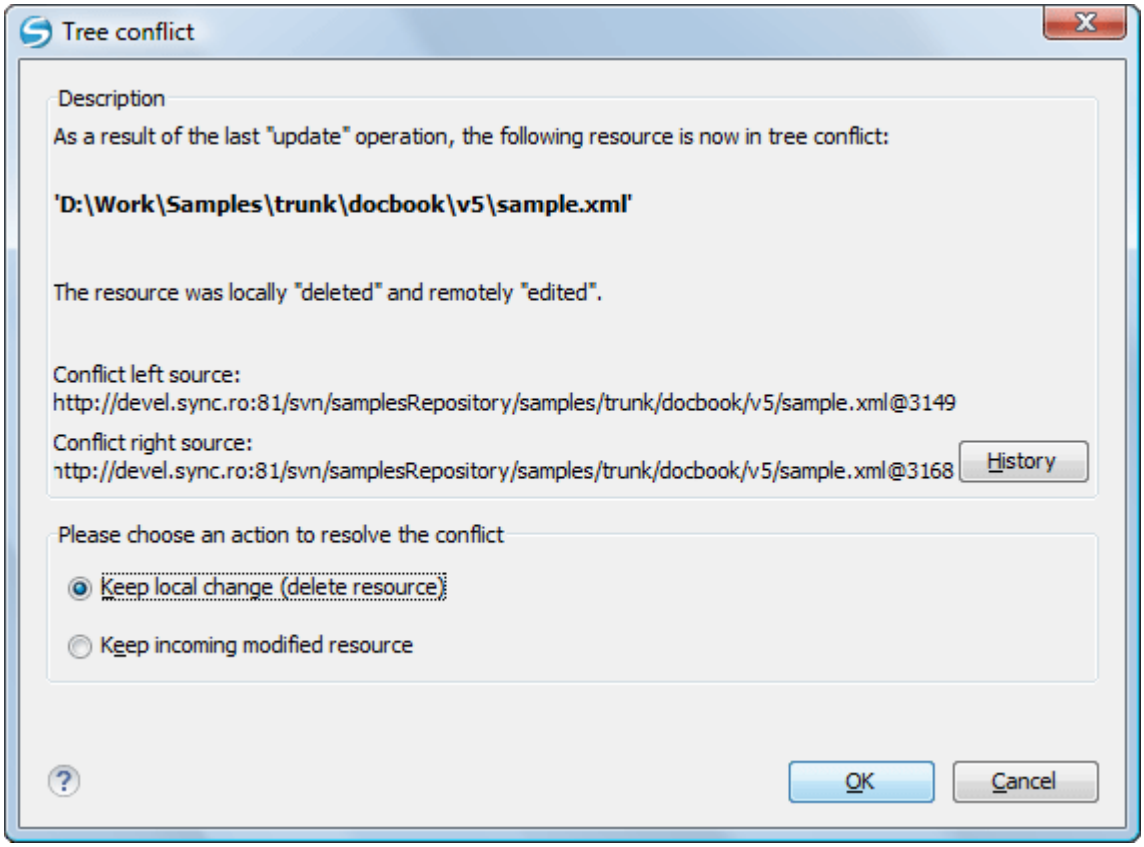
A *tree conflict* is a conflict at the directory tree structure level and occurs when the user runs an update action on a resource that has the following conditions:

- It is locally modified and the same resource was deleted from the repository (or deleted as a result of being renamed or moved).
- It was locally deleted (or deleted as a result of being renamed or moved) and the same resource is incoming as modified from the repository.

The same conflict situation can occur after a merge or a switch action. The action ends with an error and the folder containing the file that is now in the tree conflict state is also marked with a conflict icon.

Such a conflict can be resolved in one of the following ways that are available when the user double clicks on the conflicting resource or when running the **Edit conflict** action:

Figure 719. Resolve a tree conflict



- **Keep local change (delete resource)** - Keeps the incoming change that comes from the repository.
- **Keep incoming modified resource** - If there is a renamed version of the file committed by other user that will be added to the working copy too.

Update the Working Copy

While you are working on a project, other members of your team may be committing changes to the project repository. To get these changes, you have to *update* your working copy. Updating may be done on single files, a set of selected files, or recursively on entire directory hierarchies. The update operation can be performed from **Working Copy** view *(on page 2990)*. It updates the selected resources to the last synchronized revision (if remote information is available) or to the *HEAD* revision of the repository.

There are three different kinds of incoming changes:

- *Non-conflicting* - A non-conflicting change occurs when a file has been changed remotely but has not been modified locally.
- *Conflicting, but auto-mergeable* - An auto-mergeable conflicting change occurs when a text file has been changed both remotely and locally (for example, has non-committed local changes) but the changes are on different lines of text. Not applicable to binary resources (for example, multimedia files, PDFs, executable program files)
- *Conflicting* - A conflicting change occurs when one or more of the same lines of a text file have been changed both remotely and locally.

If the resource contains only incoming changes or the outgoing changes do not intersect with incoming ones then the update will end normally and the Subversion system will merge incoming changes into the local file. In the case of a conflicting situation the update will have as result a file with conflict status.

The Oxygen XML Editor allows you to update your working copy files to a specific revision, not only the most recent one. This can be done by using the **Update to revision/depth** action from the **Working Copy** view (**All Files** view mode) or the **Update to revision** action from the **History** view *(on page 3005)* contextual menu.

If you select multiple files and folders and then you perform an **Update** operation, all of those files and folders are updated one by one. The Subversion client makes sure that all files and folders belonging to the same repository are updated to the exact same revision, even if between those updates another commit occurred.

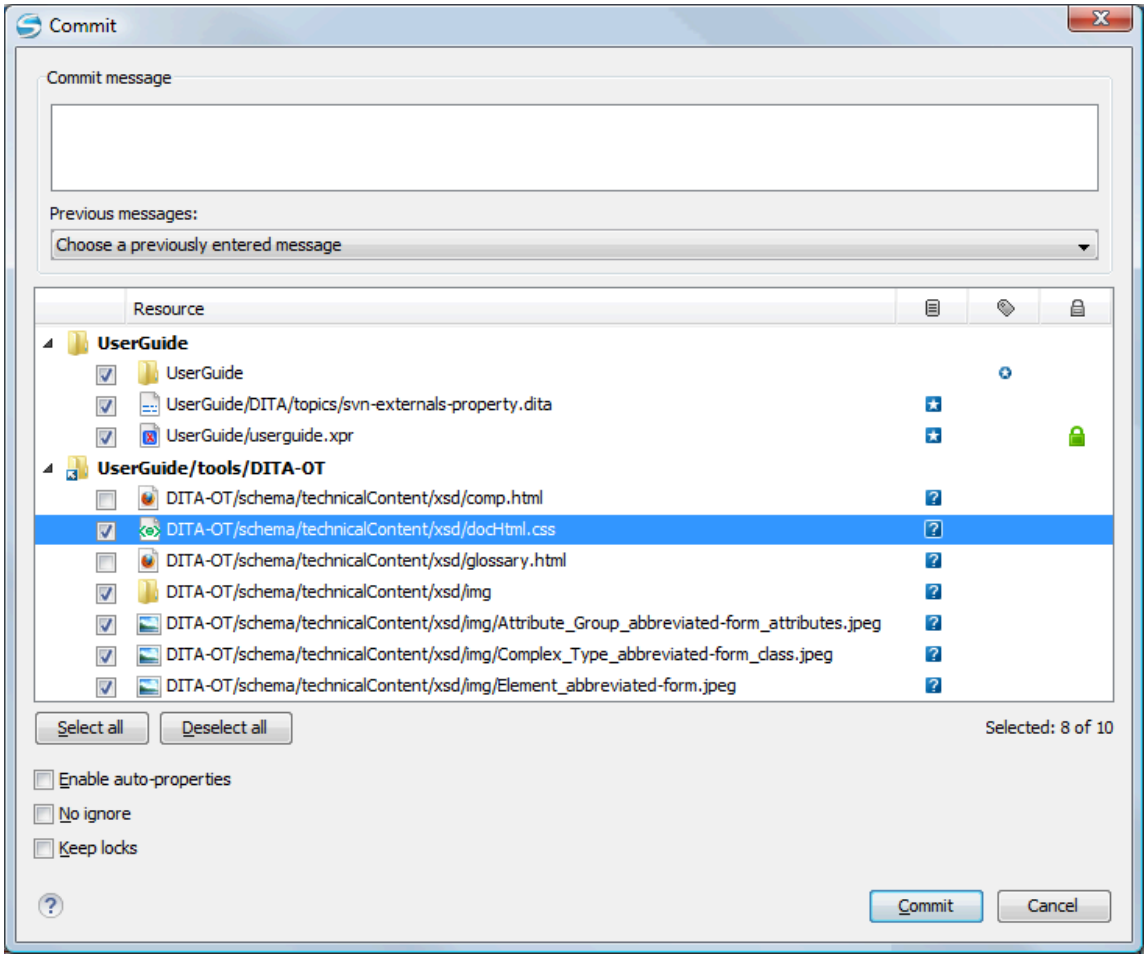
When the update fails with a message saying that there is already a local file with the same name Subversion tried to check out a newly versioned file, and found that an unversioned file with the same name already exists in your working folder. Subversion will never overwrite an unversioned file unless you specifically do this with an **Override and update** action. If you get this error message, the solution is simply to rename the local unversioned file. After completing the update, you can check to see if the renamed file is still needed.

Send Your Changes to the Repository

Sending the changes you made to your working copy is known as *committing* the changes. If your working copy is up-to-date and there are no conflicts, you are ready to commit your changes.

The **Commit** action sends the changes from your local working copy to the repository. The **Commit** dialog box presents all the items that you can commit.

Figure 720. Commit dialog box



Enter a message to associate with the commit, or choose a previous message from the **Previous messages** list (the last 10 commit messages will be remembered even after restarting the SVN client application).

An item that can be committed has one of the following states: *added*, *modified* (content or properties), *replaced*, and *deleted*. All items that have one of these states are selected in the dialog box by default. If you do not want to commit one of the items, deselect it.

Attention:
For SVN 1.8 working copies: when committing items that were moved and/or renamed, make sure you select both the source and the destination. Otherwise, the commit operation will fail.

Besides the items that have one of the mentioned states, Syncro SVN Client also includes the files being *unversioned* or *missing* and these items are handled automatically:

- *Unversioned* items are added under version control.
- *Missing* items are deleted.

Note:
If the **Show unversioned directories content** option is not selected, the **Commit** dialog box does not display the items inside an *unversioned*directory.

Unversioned or *missing* items are not selected by default in the **Commit** dialog box, unless you have selected them explicitly when issuing the commit command.

Note:
In some cases, items that have one of the above states are not presented in the **Commit** dialog box.

For example:

- Items that have been *added* or *replaced* previously, but now are presented as *missing* after being removed from the file system, outside of an SVN client. Such items do not exist in the repository and you should use the **Delete** action to remove them from your working copy.
- Items that have incoming changes from the repository, after a synchronization. You need to have your working copy up-to-date before committing your changes.
- Files that, after a synchronization, appear as locked by other users or from other locations than the current working copy.

Note:
Due to dependencies between items, when you select or clear an *unversioned* ( ) or *added* ( ) item in the **Commit** dialog box, other items with one of these states can be selected or cleared automatically.

The modifications that will be committed for each file can be reviewed in the compare editor window by double-clicking a file in the **Commit** dialog box, or by right-clicking and selecting the **Show Modifications** action from the contextual menu. This option is available to review only file content changes, not property changes.

The **Local file status** column indicates the actual state of the items and the **Local properties status** column indicates whether or not the properties of an item are modified.

The **Lock information** column is displayed if at least one of the files in the **Commit** dialog box has lock information associated with it, valid against the commit operation.

The following options are available in this dialog box:

- **Enable automatic properties** or **Disable automatic properties** - enables or disables automatic property assignment (per runtime configuration rules), overriding the `enable-auto-props` runtime configuration directive, defined in the `config` file of the Subversion configuration directory.

  > **Note:**
  > This option is available only when there are defined properties to be applied automatically for resources newly added under version control. You can define these properties in the `config` file of the Subversion configuration directory, in the `auto-props` section. Based on the value of the `enable-auto-props` runtime configuration directive, the presented option is either **Enable automatic properties**, or **Disable automatic properties**.

- **Keep locks** - selecting the **Keep locks** option preserves any locks you set on various files.

  > **Note:**
  > This option is available only when files that you locked are presented in the dialog box.

Each of the above options is activated only when you select an item that can have the option applied.

Your working copy must be up-to-date with respect to the resources you commit. This is ensured by using the **Update** action prior to committing, resolving conflicts and re-testing as needed. If your working copy resources you are trying to commit are out of date you will get an appropriate error message.

Committing to Multiple Locations

Although Subversion does not support committing to multiple locations at once, Syncro SVN Client offers this functionality regarding *external* items.

If items to be committed belong to different *external* definitions than those found in the working copy, they are grouped under the corresponding item that indicates their repository origin. Each parent item is rendered bold and its corresponding repository location is presented when hovering it. Parent items are decorated with a small arrow ( ) if they are *external* definitions. The working copy root directory is never decorated and is not presented if there are no *external* items listed (all items belong to the main working copy). Each child item is presented relative to the parent item.

> **Note:**
> When an *external* directory has modifications of its own, it is presented both as a parent item and as an item that you can select and commit. This is always the case for *external* files.

The sets of items belonging to *external* definitions from the same repository are committed together, resulting a single revision. So, the number of revisions can be smaller than the number of *externals*. External definitions are considered from the same repository if they have the same protocol, server address, port, and repository address within the server.

Note:
External files are always from the same repository as the parent directory that defines them, so they are always committed together with the changes from their parent directory.

Integration with Bug Tracking Tools

Users of bug tracking systems can associate the changes they make in the repository resources with a specific ID in their bug tracking system. The only requirement is that the user includes the bug ID in the commit message that they enter in the **Commit** dialog box. The format and the location of the ID in the commit message are configured with SVN properties.

To make the integration possible Syncro SVN Client needs some data about the bug tracking tool used in the project. You can configure this using the following SVN properties *(on page 2944)* that must be set on the folder that contains resources associated with the bug tracking system (usually they are set recursively on the root folder of the working copy):

- **bugtraq:message** - A string property. If it is set the **Commit** dialog box *(on page 2938)* will display a text field for entering the bug ID. It must contain the string *%BUGID%*, which is replaced with the bug number on commit.
- **bugtraq:label** - A string property that sets the label for the text field configured with the **bugtraq:message** property.
- **bugtraq:url** - A string property that is the URL pointing to the bug tracking tool. The URL string should contain the substring *%BUGID%* which Syncro SVN Client replaces with the issue number. That way the resulting URL will point directly to the correct issue.
- **bugtraq:warnifnoissue** - A boolean property with the values *true*/*yes* or *false*/*no*. If set to *true*, the Syncro SVN Client will warn you if the bug ID text field is left empty. The warning will not block the commit, only give you a chance to enter an issue number.
- **bugtraq:number** - A boolean property with the value *true* or *false*. If this property is set to *false*, then any character can be entered in the bug ID text field. If the property is set to *true* or is missing then only numbers are allowed as the bug ID.
- **bugtraq:append** - A boolean property. If set to *false*, then the bug ID is inserted at the beginning of the commit message. If *yes* or not set, then it is appended to the commit message.
- **bugtraq:logregex** - This property contains one or two regular expressions, separated by a newline. If only one expression is set, then the bug ID's must be matched in the groups of the regular expression string (for example, `[Ii]ssue #?(\d+)`). If two expressions are set, then the first expression is used to find a string which relates to a bug ID but may contain more than just the bug ID (for example, `Issue #123` or `resolves issue 123`). The second expression is then used to extract the bug ID from the string extracted with the first expression. An example: if you want to catch every pattern `issue #XXX` and `issue #890, #789` inside a log message you could use the following strings:
  - `[Ii]ssue #?(\d+)(,? ?#?(\d+))+`
  - `(\d+)`

The data configured with these SVN properties is stored on the repository when a revision is committed. A bug tracking system or a statistics tool can retrieve the revisions that affected a bug from the SVN server and present the commits related to that bug to the user of the bug tracking system.

If the **bugtraq:url** property was filled in with the URL of the bug tracking system and this URL includes the *%BUGID%* substring as specified above in the description of the **bugtraq:url** property then the **History** view *(on page 3005)* presents the bug ID as a hyperlink in the commit message. Clicking such a hyperlink in the commit message of a revision opens a Web browser at the page corresponding to the bug affected by that commit.

Obtain Information for a Resource

This section explains how to obtain information for a SVN resource:

Request Status Information for a Resource

While you are working with the SVN Client you often need to know which files you have changed, added, removed, or renamed, or even which files got changed and committed by others. This is where the **Synchronize** action from the **Working Copy** view *(on page 2990)* comes in handy. The **Working Copy** view shows you every file that has changed your working copy, as well as any unversioned files you may have.

If you want more detailed information about a given resource, you can use the  **Show SVN Information** action. This action is available from the **File** menu or the contextual menu of the **Working Copy**, **Repositories**, **History**, or **Directory Change Set** views, or from the **Revision Graph** dialog box. The **SVN Information** dialog box will be displayed, showing information about the selected resource. The information displayed depends on the location of the item (local or remote) and may include the following:

- Local path and repository location
- Revision number
- Last change author, revision and date
- Information about locks
- Local file status
- Local properties status
- Local directory depth
- Repository location and revision number for copied files or directories
- Path information about locally moved items
- Path information about conflict generated files
- Remote file status
- Remote properties status
- File size and other information

The value of a property of the resource displayed in the dialog box can be copied by right-clicking the property and selecting the **Copy** action.

Request History for a Resource

In Apache Subversion™, both files and directories are versioned and have a history. If you want to examine the history for a selected resource and find out what happened at a certain revision you can use the **History view** that can be accessed from Repositories view *(on page 2985)*, Working Copy view *(on page 2990)*, Revision Graph *(on page 3020)*, or Directory Change Set view *(on page 3010)*. From the **Working copy view** you can display the history of local versioned resources. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Related Information:
History View *(on page 3005)*

Management of SVN Properties

In the **Properties** view *(on page 3018)* you can read and set the Apache Subversion™ properties of a file or folder. There is a set of predefined properties with special meaning to Subversion. For more information about properties in Subversion see the SVN Subversion specification. Subversion properties are revision-dependent. After you change, add or delete a property for a resource, you have to commit your changes to the repository.

If you want to change the properties of a given resource you need to select that resource from the **Working Copy** view *(on page 2990)* and run the **Show properties** action from the contextual menu. The **Properties** view *(on page 3018)* will show the local properties for the resource in the working copy. Once the Properties view is visible, it will always present the properties of the currently selected resource. There are actions available in the **Properties** view toolbar *(on page 3019)* that allows you to add, change, and delete the properties.

If you choose the **Add a new property** action, a new dialog box will appear that contains the following:

- **Name** - Combo box that allows you to enter the name of the property. The drop-down menu of the combo box presents the predefined Subversion properties (such as **svn:ignore**, **svn:externals**, **svn:needs-lock**, etc.)
- **Current value** - Text area that allows you to enter the value of the new property.

If the selected item is a directory, you can also set the property recursively on its children by selecting the **Set property recursively** checkbox.

If you want to change the value for a previously set property, you can use the **Edit property** action, which will display a dialog box with the following information:

- **Name** - Property name (cannot be changed).
- **Current value** - The current value (can be changed).
- **Base value** - The value of the property, if any, from the resource in the pristine copy (cannot be changed).

If you want to completely remove a property previously set you can choose the **Remove property** action. It will display a confirmation dialog box where you can also choose if the property will be removed recursively.

There is a **Refresh** action in the **Properties** view *(on page 3018)* that can be used when the properties have been changed from outside the view. This can happen, for example, when the view was already presenting the properties of a resource and they have been changed after an **Update** operation.

Branches and Tags

One of the fundamental features of version control systems is the ability to create a new line of development from the main one. This new line of development will always share a common history with the main line if you look far enough back in time. This line is known as a *branch*. Branches are mostly used to try out features or fixes. When the feature or fix is finished, the branch can be merged back into the main branch (*trunk*).

Another feature of version control systems is the ability to take a snapshot of a particular revision, so you can at any time recreate a certain build or environment. This is known as *tagging*. Tagging is especially useful when making release versions.

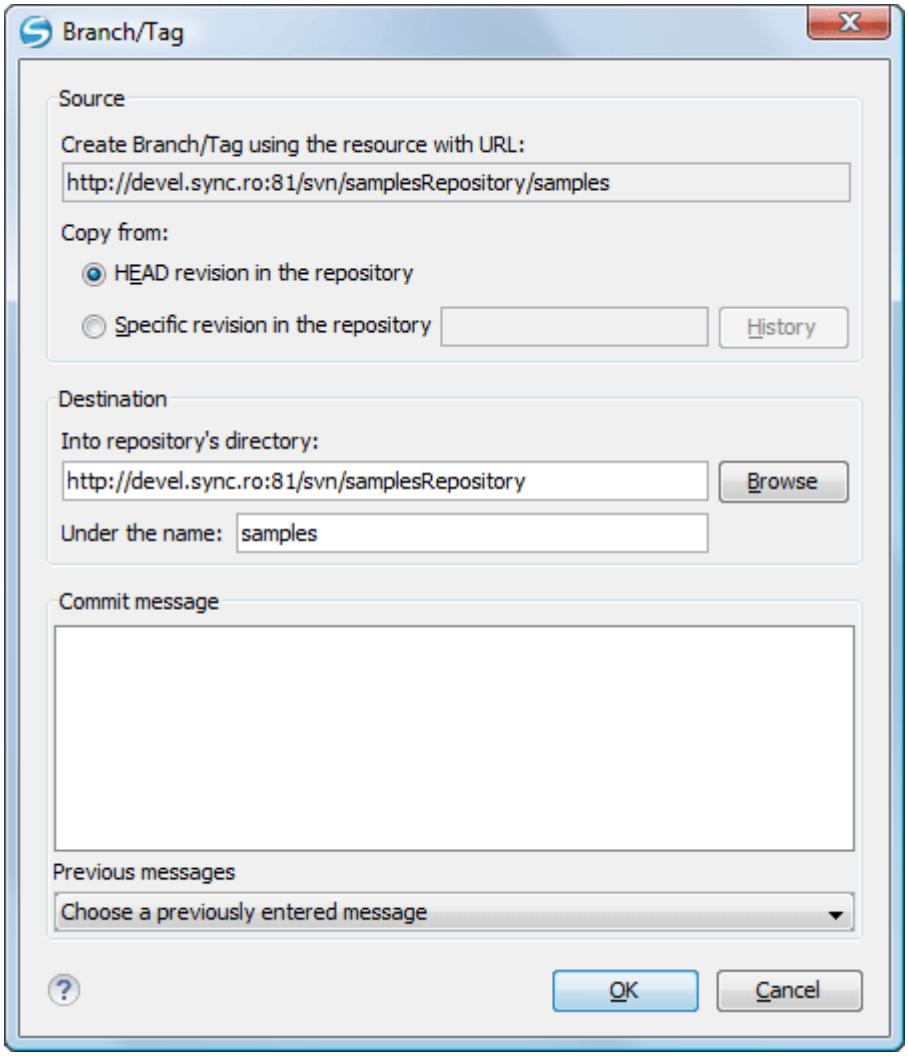
In Apache Subversion™, there is no difference between a *tag* and a *branch*. On the repository, both are ordinary directories that are created by copying. The trick is that they are cheap copies instead of physical copies. Cheap copies are similar to hard links in Unix, which means that they merely link to a specific tree and revision without making a physical copy. As a result, branches and tags occupy little space on the repository and are created very quickly.

Provided that nobody ever commits to the directory in question, it remains a tag. If people start committing to it, it becomes a branch.

Create a Branch / Tag

To create a branch or tag by copying a directory, use the **Branch/Tag** action that is available in the **Tools** menu when an item is selected in the **Working Copy** view *(on page 2990)* or **Repositories** view *(on page 2985)*, or from the contextual menu of the **Repositories** view.

Figure 721. Branch/Tag Dialog Box



You can configure the following options in this dialog box:

You can specify the source revision of the copy in the **Copy from** section. You can choose between the following options:

- **HEAD revision in the repository** - The new branch or tag will be copied in the repository from the `HEAD` revision. The branch will be created very quickly, as the repository will make a *cheap* copy.
- **Specific revision in the repository** - The new branch will be copied into the repository, but you can specify the exact desired revision. For example, this is useful if you forgot to make a branch or tag when you released your application. If you click the **History** button you can select the revision number from the **History** dialog box *(on page 2918)*. This type of branch will also be created very quickly.
- **Working copy** - (Available only if the item is selected from the **Working copy** view). The new branch will be a copy of your local working copy. If you have updated some files to an older revision in your working copy, or if you have made local changes, that is exactly what goes into the copy. This involves transferring some data from your working copy back to the repository, or more specifically, the locally modified files.

You can specify the location of the new branch or tag in the **Destination** section:

- **Into repository's directory** - The URL of the parent directory *(on page 3025)* of the new branch or tag.

  > **Note:**
  > *Peg revisions* have no effect for this operation since it is used to send information to the repository.

- **Under the name** - You can specify another branch or tag name other than the name of the resource selected in the **Repositories** or **Working copy** view.

The new branch or tag will be created as a child of the specified URL of the repository directory and will have the new name.

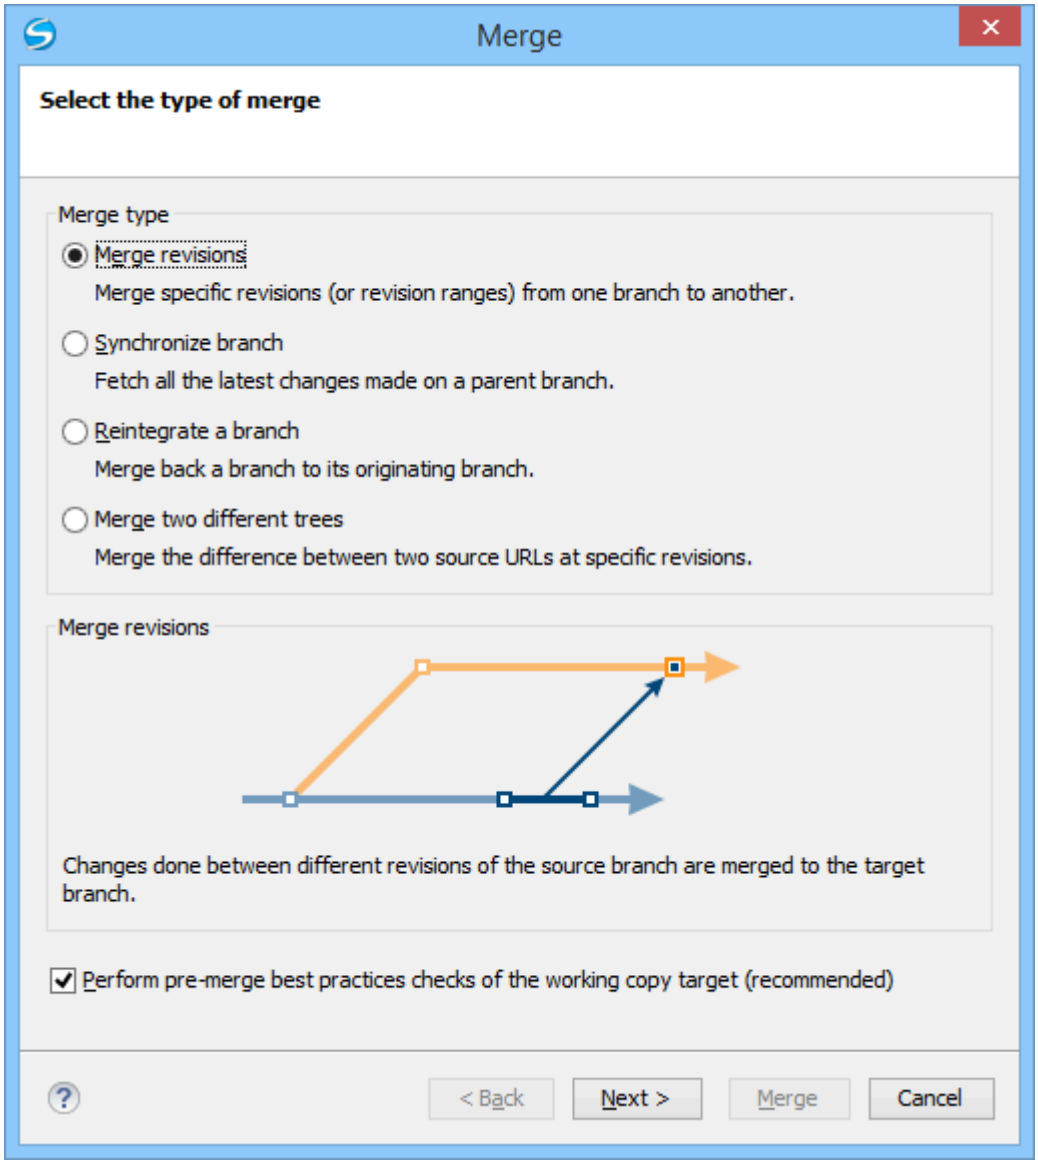
Merging

At some stage during the development process, you will want to merge the changes made on a *branch* back into the *trunk*, or vice-versa. The *merge* is accomplished by comparing two points (branches or revisions) in the repository and applying the obtained differences to your working copy. This process is closely related to the *diff* concept.

> **Note:**
> A *branch* is a line of development that exists independently of another line, yet still shares a common history if you look far enough back in time. A *branch* always begins life as *a copy of something* (such as a trunk, another branch, or tag), and moves on from there, generating its own history.

The **Merge** action is available in the **Tools** menu. The working copy item selected when you issued the command will be the one receiving the generated changes. If there is no item selected, the *merge* operation will be performed on the entire working copy.

Figure 722. Merge Wizard



The four types of merging are as follows:

- **Merge revisions** *(on page 2951)* - Port changes from one branch to another. Note that the *trunk* can also be considered a branch, in this context.
- **Synchronize branch** *(on page 2953)* - Fetch all the changes made on a parent branch (or the *trunk*) to a child branch.
- **Reintegrate a branch** *(on page 2955)* - Merge a branch back to its parent branch (can also be the *trunk*).
- **Merge two different trees** *(on page 2957)* - Integrate the changes done on a branch to a different branch.

It is recommended that you enable the following pre-merge check:

Perform pre-merge best practices checks of the working copy target *(on page 2949)* - When selected, the SVN Client checks if the working copy target item is ready for the merge operation and displays the **pre-merge checks** wizard page.

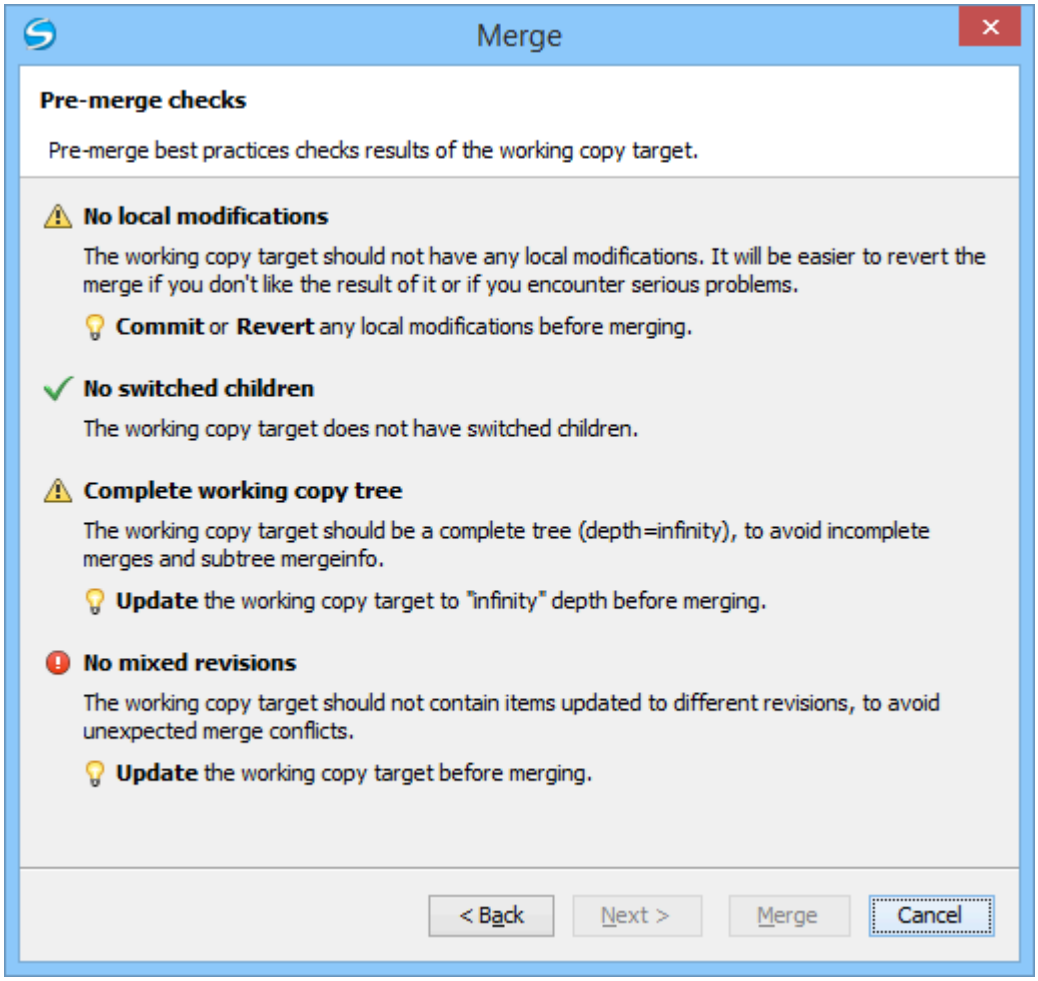
Remember:
It is a good idea to perform a merge into an unmodified working copy. If you have made changes to your working copy, commit them first. If the *merge* does not go as you expect, you may want to revert the changes and revert cannot recover your uncommitted modifications.

Important:
The above recommendation becomes mandatory when *reintegrating a branch (on page 2947)*.

Pre-Merge Checks

Before performing a merge, it is recommended to make sure that the working copy target item is ready for the merge operation. The SVN Client includes a best practices step that checks various conditions of the working copy target item to ensure that the merge operation will succeed. By selecting the **Perform pre-merge best practices checks of the working copy target** option in the first page of the **Merge** wizard, the **Pre-merge checks** wizard page is displayed to give you a summary of the verified conditions.

Figure 723. Pre-Merge Checks Wizard Page



The following conditions are checked in this operation:

No local modifications

The working copy item (or any of its children) receiving the merge should not contain uncommitted changes, to make it easier to revert merge-generated changes if you encounter unexpected results.

> **Tip:**
> If this condition fails, you should *commit* or *revert* the local modifications before merging.

No switched children

None of the children of the working copy item receiving the merge should be switched, to avoid incomplete merges and *subtree mergeinfo*.

> **Tip:**
> If this condition fails, you should switch back all the children before merging.

Complete working copy tree

The working copy item receiving the merge should be a complete directory tree structure with an infinite depth, to avoid incomplete merges and *subtree mergeinfo*.

> **Tip:**
> If this condition fails, you should change the *sticky* depth of the working copy item receiving the merge to *infinity* value.

No mixed revisions

To avoid unexpected merge conflicts, the working copy item that is receiving the merge should not contain items that were updated to other revisions.

> **Tip:**
> If this condition fails, you should *update* the working copy before merging.

Each condition is marked with an icon that represents the state of the condition. The possible states are as follows:

- (**Successful**) - The condition is fulfilled successfully.
- (**Warning**) - The condition is not fulfilled, but it is not mandatory.
- (**Error**) - The condition is not fulfilled and is mandatory (therefore, the operation cannot proceed until you solve the error).

Tip:
For each condition state, a message is displayed that gives you additional information about the results and, for warning or errors, a hint that explains how you can solve them.

Important:
After solving any of the warnings or errors, it is recommended that you perform the *pre-merge checks* again to make sure your new changes are valid.

Merge Revisions

This case is when you have made one or more changes to a branch and you want to duplicate them in another branch. For example, suppose you know that a problem has been fixed by committing revisions `17`, `20`, and `25` on branch `B1`. These changes are also needed in branch `B2`. Thus, to merge them, you need a working copy of the `B2` branch.

To merge revisions from a different branch, follow these steps:

1. Go to menu **Tools > Merge**.
   The **Merge** wizard is opened.
2. Select the **Merge revisions** option.
3. It is recommended that you select the **Perform pre-merge best practices checks of the working copy target** option to make sure that the working copy target item is ready for the merge operation.

   a. Click the **Next** button.
      If the **Perform pre-merge best practices checks of the working copy target** option is selected, the **Pre-Merge Checks** wizard page *(on page 2949)* is displayed.

      Note:
      If errors are found you need to solve them before proceeding.

4. Click the **Next** button.
   The **Merge revisions** wizard page is displayed.
5. In the **Merge from (URL)** text box, enter the URL of the *branch* or *tag (on page 3025)* that contain the changes that you want to duplicate in your working copy.
   You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop-down menu, which displays a history of previously used URLs.

   Note:
   If the URL belongs to a different repository than the working copy, the **Ignore ancestry / Disable merge tracking** option (in the **Merge Options** wizard page *(on page 2960)*) will be selected

automatically (and you cannot change this). This is because the Subversion client cannot track changes between different repositories *(on page 2963)*.

Tip:
You can also specify a *peg revision (on page 3027)* at the end of the URL (for example, `URL@rev1234`). The peg revision does not affect the merge range you select. By default, the `HEAD` revision is assumed.

6. In the **Revisions to merge** section, choose between the **all revisions** and **specific revision(s)** options.
   - **all revisions** - The operation will include *all eligible revisions* that were not yet merged.
   - **specific revision(s)** - You can specify one or more individual revisions and/or revision ranges. Also, you can mix *forward* ranges (for example, `1-5`), *backward* ranges (for example, `20-15`), and subtract specific revisions from a range (for example, `1-5, -3`).

Note:
If using the Subversion command-line client, a revision range of the form `1-5` means all changes starting from revision 2 up to revision 5 (the changes necessary to reach revision 5, committed after revision 1). Unlike the Subversion command-line client, in Syncro SVN Client the revision ranges are inclusive, meaning that it will process all revisions, starting with revision 1, up to and including revision 5.

Attention:
The `HEAD` revision is the only non-numerical revision allowed, and it can only be used when specifying revision ranges as one of the ends of the range (for example, `10-HEAD`). Be careful when using it, as it might not refer to the desired revision, if it has recently been committed by another user.

Tip:
If you want to perform a *reverse merge* and roll-back your working copy changes that have already been committed to the repository, use the *negative revisions* notation (for example, `-7`) or *backward revision ranges* (for example, `20-10`).

   a. If you click the **History** button, the **History** dialog box *(on page 2918)* is displayed, which allows you to select one or more revisions to be merged.

7. Optionally, if you want to configure the options *(on page 2960)* for your merge, click the **Next** button. The **Merge Options** wizard page *(on page 2960)* is displayed that allows you to configure options for the operation.

Warning:
If the **Ignore ancestry / Disable merge tracking** option is selected and you chose **all revisions** in the **Revisions to merge** section, revisions that were previously merged will also be included, which may result in conflicts.

8. Click the **Merge** button.
   The merge operation is performed.

If the merge is completed successfully, all the changes corresponding to the selected revisions should be merged in your working copy.

It is recommended to look at the results of the merge, in the working copy, to review the changes and see if it meets your expectations. Since merging can sometimes be complicated, you may need to resolve conflicts *(on page 2962)* after making major changes.

Note:
The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Synchronize a Branch

While working on your own branch, other people on your team might continue to make important changes in the parent branch (which can be the *trunk* itself or any other branch). It is recommended to periodically duplicate those changes in your branch to make sure your changes are compatible with them. This is done by performing a *synchronize merge*, which will bring your branch up-to-date with any changes made to its ancestral parent branch since your branch was last created or synchronized. Subversion is aware of the history of your branch and can detect when it split away from the parent branch.

Frequently keeping your branch in sync with the parent branch helps you to prevent unexpected conflicts when the time comes for you to duplicate your changes back into the parent branch. The synchronization uses *merge tracking* to skip all those revisions that have already been merged, thus a sync merge can be repeated periodically to fetch all the latest changes of the parent branch to keep up-to-date with it.

Important:
It is recommended to synchronize the whole working copy that was created from the child branch (the root of the working copy), rather than just a part of it.

After running the *synchronize merge*, your working copy from the child branch now contains new local modifications, and these edits are duplications of all of the changes that have happened on the *trunk* since you first created your branch. At this point, your private branch is now synchronized with the trunk.

To synchronize your branch with its parent branch, follow these steps:

1. Go to **Tools > Merge**.
   The **Merge** wizard is opened.
2. Select the **Synchronize branch** option.
3. It is recommended that you select the **Perform pre-merge best practices checks of the working copy target** option to make sure that the working copy target item is ready for the merge operation.

   a. Click the **Next** button.
      If the **Perform pre-merge best practices checks of the working copy target** option is selected, the **Pre-Merge Checks** wizard page *(on page 2949)* is displayed.

      Note:
      If errors are found you need to solve them before proceeding.

4. Click the **Next** button.
   The **Synchronize branch** wizard page is displayed.
5. In the **Parent branch (URL)** text box, enter the URL of the *branch* where you created your branch *(on page 3025)*. This means that the URL must belong to the same repository as your working copy that was created from the child branch.
   You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop-down menu, which displays a history of previously used URLs.

   Tip:
   You can also specify a *peg revision (on page 3027)* at the end of the URL (for example, `URL@rev1234`). The peg revision specifies both the peg revision of the URL and the latest revision that will be considered for merging. By default, the `HEAD` revision is assumed.

6. Optionally, if you want to configure the options *(on page 2960)* for your merge, click the **Next** button.
   The **Merge Options** wizard page *(on page 2960)* is displayed that allows you to configure options for the operation.

   Note:
   The **Ignore ancestry / Disable merge tracking** option is not available for this merge type, since a synchronization merge should always be recorded in the destination branch.

7. Click the **Merge** button.
   The merge operation is performed.

If the merge is completed successfully, all the changes corresponding to the selected revisions should be merged in your working copy.

It is recommended to look at the results of the merge, in the working copy, to review the changes and see if it meets your expectations. Since merging can sometimes be complicated, you may need to resolve conflicts *(on page 2962)* after making major changes.

Note:
The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Reintegrate a Branch

Prerequisites:
There are some conditions that apply to reintegrate a branch:

- The server must support merge tracking.
- The source branch (to be reintegrated) must be coherently synchronized with its parent branch. This means that all revisions between the branching point and the last revision merged from the parent branch to the child branch must be merged to the latter one (there must be no missing revisions in-between).
- The working copy **must not** contain the following:
  - Local modifications.
  - A mixture of revisions (all items must point to the same revision).
  - Sparse directories (all directories must be of **infinity** depth).
  - Switched items.
- The revision of the working copy must be greater than or equal to the last revision of the parent branch with which the child branch was synchronized.

Tip:
You can use the *pre-merge checks* option *(on page 2949)* to make sure these conditions are fulfilled.

This method is useful when you have a feature branch on which the development has concluded and it should be merged back into its parent branch. Since you have kept the feature branch synchronized with its parent, the latest versions of them will be absolutely identical except for your feature branch changes. These changes can be reintegrated into the parent branch by using a working copy of it and the **Reintegrate a branch** option.

This method uses the *merge-tracking* features of Apache Subversion™ to automatically calculate the correct revision ranges and to perform additional checks that will ensure that the branch to be reintegrated has been fully updated with its parent changes. This ensures that you do not accidentally undo work that others have committed to the parent branch since the last time you synchronized the child branch with it. After the merge, all branch development will be completely merged back into the parent branch, and the child branch will be redundant and can be deleted from the repository.

Tip:
Before reintegrating the child branch it is recommended to synchronize it with its parent branch one more time, to help avoid any possible conflicts.

To reintegrate a child branch into its parent branch, follow these steps:

1. Go to menu **Tools > Merge**.
   The **Merge** wizard is opened.
2. Select the **Reintegrate a branch** option.

   Note:
   This option is not available if the selected working copy item (or if it is a directory, any of the items inside of it) has any type of modification. This is because it is mandatory for the target item to have no modifications.

3. It is recommended that you select the **Perform pre-merge best practices checks of the working copy target** option to make sure that the working copy target item is ready for the merge operation.

   a. Click the **Next** button.
      If the **Perform pre-merge best practices checks of the working copy target** option is selected, the **Pre-Merge Checks** wizard page *(on page 2949)* is displayed.

      Note:
      If errors are found you need to solve them before proceeding.

4. Click the **Next** button.
   The **Reintegrate a branch** wizard page is displayed.
5. In the **Child branch (URL)** text box, enter the URL of the child *branch* to be reintegrated *(on page 3025)*.
   This means that the URL must belong to the same repository as your working copy that was created from the parent branch.
   You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop-down menu, which displays a history of previously used URLs.

   Tip:
   You can also specify a *peg revision (on page 3027)* at the end of the URL (for example, `URL@rev1234`). The peg revision specifies both the peg revision of the URL and the latest revision that will be considered for merging. By default, the `HEAD` revision is assumed.

   The **Merge Options** wizard page *(on page 2960)* is displayed that allows you to configure options for the operation.

> **Note:**
> Since a *reintegrate merge* is so specialized, most of the merge options are not available, except for those in the **File Comparison** category.

6. Click the **Merge** button.
   The merge operation is performed.

If the merge is completed successfully, all the changes corresponding to the selected revisions should be merged in your working copy.

It is recommended to look at the results of the merge, in the working copy, to review the changes and see if it meets your expectations. Since merging can sometimes be complicated, you may need to resolve conflicts *(on page 2962)* after making major changes.

> **Note:**
> The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Merge Two Different Trees

This merge type is useful when you need to duplicate changes from one child branch (for example, `CB1`) to another child branch (`CB2`) from the same parent branch. The SVN client will calculate the changes necessary to get from the `HEAD` revision of the parent branch (or the *trunk*) to the `HEAD` revision of one of its child branches (`CB1`), and apply those changes to your working copy of the other branch (`CB2`). The result is that the latter child branch (`CB2`) will also include the changes made on the original child branch (`CB1`), although that branch was not reintegrated into the parent branch.

This merge type could also be used to reintegrate a child branch back into its parent when the repository does not support *merge tracking*.

> **Note:**
> If the server does not support *merge-tracking*, then this is the only way to merge a branch back to its parent.

1. Go to menu **Tools > Merge**.
   The **Merge** wizard is opened.
2. Select the option **Merge two different trees**.
3. It is recommended that you select the **Perform pre-merge best practices checks of the working copy target** option to make sure that the working copy target item is ready for the merge operation.

a. Click the **Next** button.
   If the **Perform pre-merge best practices checks of the working copy target** option is selected, the **Pre-Merge Checks** wizard page *(on page 2949)* is displayed.

   > **Note:**
   > If errors are found you need to solve them before proceeding.

4. Click the **Next** button.
   The **Merge two different trees** wizard is displayed.
5. In the **From (starting URL and revision)** section, enter the URL of the first branch *(on page 3025)*.
   You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop-down menu, which displays a history of previously used URLs.

   > **Tip:**
   > If you are using this method to merge a feature branch back to its parent branch, you need to start the merge wizard from within a working copy of the parent. In this field enter the full URL of the parent branch. This may sound wrong, but remember that the parent is the starting point to which you want to add the branch changes.

   > **Note:**
   > If the URL belongs to a different repository than the working copy, the **Ignore ancestry / Disable merge tracking** option (in the **Merge Options** wizard page *(on page 2960)*) will be selected automatically (and you cannot change this). This is because the Subversion client cannot track changes between different repositories *(on page 2963)*.

   > **Tip:**
   > You can also specify a *peg revision (on page 3027)* at the end of the URL (for example, `URL@rev1234`). By default, the `HEAD` revision is assumed.

6. Enter the last revision number at which the two trees were synchronized by choosing between **HEAD revision** and **other revision**.

   - **HEAD revision** - Use this option if you are sure that no one else has committed changes since the last synchronization.
   - **other revision** - Use this option to input a specific revision number and avoid losing recent commits. You can use the **History** button to see a list of all revisions.

7. In the **To (ending URL and revision)** section, enter the URL of the second branch *(on page 3025)*.
   You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop-down menu, which displays a history of previously used URLs.

> **Tip:**
> If you are using this method to merge a feature branch back to its parent branch, enter the URL of the feature branch. This way, only the changes unique to this branch will be merged, since the branch should have been periodically synchronized with its parent.

> **Attention:**
> The URL must point to the same repository as the one in the **From (starting URL and revision)** field. Otherwise, the operation will not be allowed, since Subversion cannot compute changes between items from different repositories.

> **Tip:**
> You can also specify a *peg revision (on page 3027)* at the end of the URL (for example, `URL@rev1234`). By default, the `HEAD` revision is assumed.

8. Select a revision to compute all changes committed up to that point by choosing between **HEAD revision** and **other revision**.
   - **HEAD revision** - This is the default selected revision.
   - **other revision** - Use this option if you want to enter a previous revision. You can use the **History** button to see a list of all revisions.
9. Optionally, if you want to configure the options *(on page 2960)* for your merge, click the **Next** button. The **Merge Options** wizard page *(on page 2960)* is displayed that allows you to configure options for the operation.

   > **Warning:**
   > If the **Ignore ancestry / Disable merge tracking** option is selected and you chose **all revisions** in the **Revisions to merge** section, revisions that were previously merged will also be included, which may result in conflicts.

10. Click the **Merge** button.
    The merge operation is performed.

If the merge is completed successfully, all the changes corresponding to the selected revisions should be merged in your working copy.

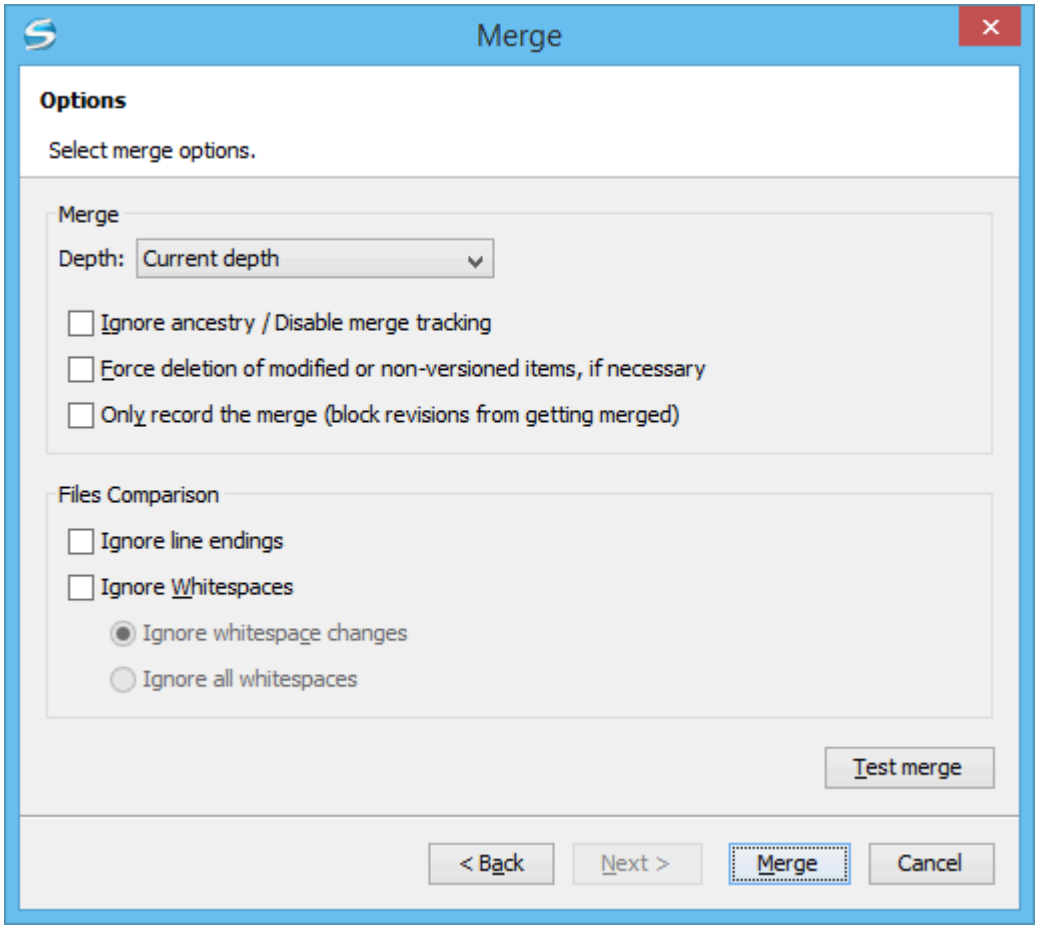
It is recommended to look at the results of the merge, in the working copy, to review the changes and see if it meets your expectations. Since merging can sometimes be complicated, you may need to resolve conflicts *(on page 2962)* after making major changes.

Note:
The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Merge Options

Here is the list of options that can be used when merging:

Figure 724. Merge Wizard - Advanced Options



- **Depth** (This option is applicable only for directories) - sets the depth of the merge operation. You can specify how far down into your working copy the merge should go by selecting one of the following values:
  - **Current depth** - Obeys the depths registered for the directories in the working copy that are to be switched.
  - **Recursive (infinity)** - Merges all the files and folders contained in the selected folder. This is the recommended depth for most users, to avoid incomplete merges and *subtree mergeinfo*.
  - **Immediate children (immediates)** - Merges only the child files and folders without recursing subfolders.
  - **File children only (files)** - Merges only the child files.
  - **This folder only (empty)** - Merges only the selected folder (no child files or folders are included).

Note:
The *depth* term is described in the Sparse checkouts *(on page 2984)* section. The default depth is the current depth of the working copy item receiving the merge.

- **Ignore ancestry / Disable merge tracking** - Changes the way two items are merged if they do not share a common ancestry. Most merges involve comparing items that are ancestrally related to one another. However, occasionally you may want to merge unrelated items. If this option is not selected, the first item will be replaced with the second item. In these situations, you would want the merge to do a path-based comparison only, ignoring any relations between the items. For example, if two different files have the same name and are in the same relative location, deselecting the option replaces one of the files with the other one, and selecting it merges their contents.

Note:
If the URL of the merge source belongs to a different repository than the URL of the target working copy item (the one receiving the changes), this option is selected automatically (and you cannot change this). This is because the Subversion client cannot track changes between different repositories *(on page 2963)*.

- **Force deletion of modified or non-versioned items, if necessary** - If not selected, when the merge operation involves deleting locally modified or non-versioned items, it will fail. This is done to prevent data loss. This option is only available if there are uncommitted changes in the working copy.
- **Only record the merge (block revisions from getting merged)** - Available when the **Ignore ancestry / Disable merge tracking** option *(on page 2961)* is not selected. It enables a special mode of the merge operation that just records it in the local merge tracking information, without actually performing it (does not modify any file contents or the structure of your working copy). You might want to select this option for two possible reasons:
  - You made (or will make) the merge manually, and therefore need to mark the revisions as being merged to make the merge tracking system aware of them. This will exclude them from future merges.
  - You want to prevent one or more particular changes from being fetched in subsequent merges.
- **Ignore line endings** - Allows you to specify how the line ending changes should be handled. By default, all such changes are treated as real content changes, but you can ignore them if you select this option.
- **Ignore whitespaces** - Allows you to specify how the whitespace changes should be handled. By default, all such changes are treated as real content changes, but you can ignore them if you select this option.

- **Ignore whitespace changes** - Ignores changes in the amount of whitespaces or to their type (for example, when changing the indentation or changing tabs to spaces).

  Note:
  Whitespaces that were added where there were none before, or that were removed, are still considered to be changes.

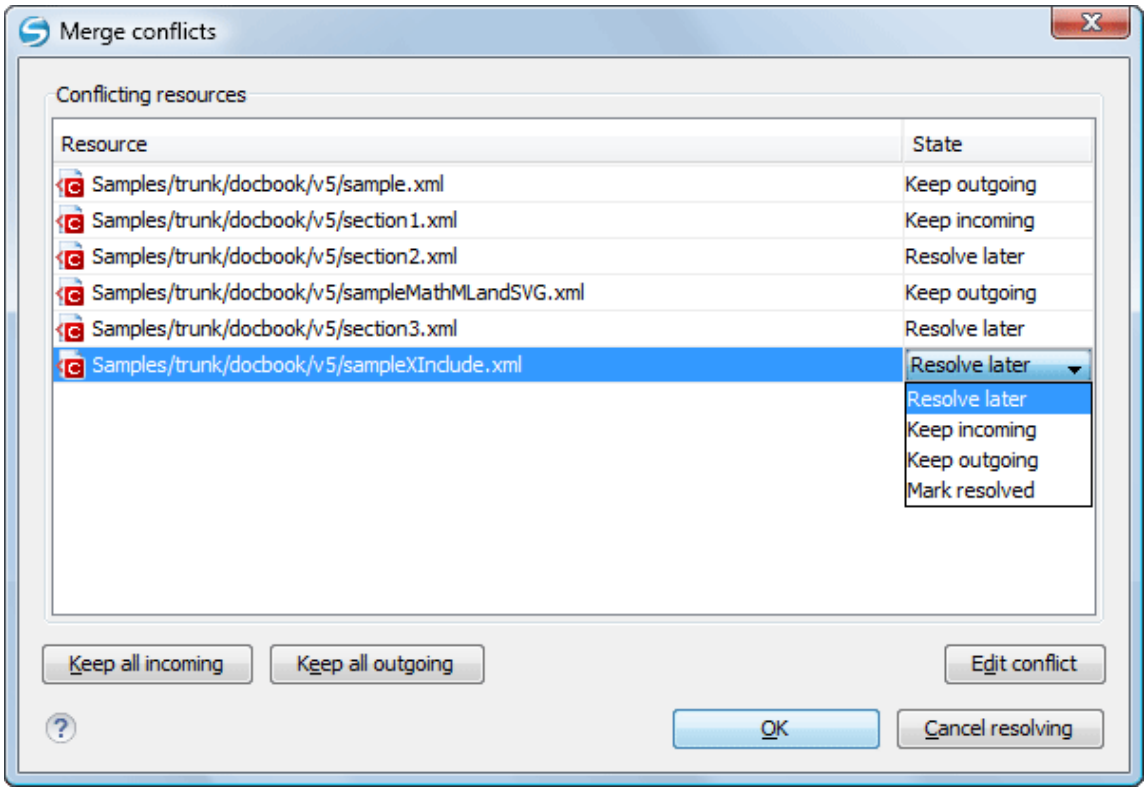
- **Ignore all whitespaces** - Ignores all types of whitespace changes.

- **Test merge** - Performs a dry run of the merge operation, allowing you to *preview* it without actually performing the merge. In the **Console** view you will see a list of the working copy items that will be affected and how they will be affected. This is helpful in detecting whether or not a merge will be successful, and where conflicts may occur.

Resolving Merge Conflicts

After the merge operation is finished, it is possible to have some items in conflict. This means that some incoming modifications for an item could not be merged with the current working copy version. If there are such conflicts, the **Merge conflicts** dialog box will appear, presenting the items that are in conflict. This dialog box offers you choices for resolving the conflicts.

Figure 725. Merge Conflicts Dialog Box



The options to resolve a conflict are as follows:

- **Resolve later** - Used for leaving the conflict as it is, to manually resolve it later.
- **Keep incoming** - This option keeps all the incoming modifications and discards all current ones from your working copy.
- **Keep outgoing** - This option keeps all current modifications from your working copy and discards all incoming ones.
- **Mark resolved** - You should choose this option after you have manually solved the conflict, to instruct the Subversion that it was resolved. To do this, use the **Edit conflict** button, which displays a dialog box that presents the contents of the conflicting items (the content of the working copy version versus the incoming version).

Additional Notes About the Merge Operation

Sub-tree Merges

It is recommended to perform a merge on the whole working copy (select its root directory when triggering the operation) to avoid *sub-tree mergeinfo*. *Sub-tree mergeinfo* is the *mergeinfo* recorded to describe a *sub-tree merge*. That is, a merge done directly to a child of a branch root that might be needed in certain situations. There is nothing special about *sub-tree merges* or *sub-tree mergeinfo* except that the complete record of merges to a branch may not be contained solely in the *mergeinfo* on the branch root and you may have to look to any *sub-tree mergeinfo* to get a full accounting. Fortunately, Subversion does this for you and rarely will you need to look for it.

Merging from Foreign Repositories

Subversion supports merging from foreign repositories. While all merge source URLs must point to the same repository, the merge target (from the working copy) may come from a different repository than the source. However, copies made in the merge source will be transformed into plain additions in the merge target. Also, *merge-tracking* is not supported for merges from foreign repositories.

Note:
When performing merges from repositories other than the one corresponding to the target item (from the working copy), the **Ignore ancestry / Disable merge tracking** option *(on page 2961)* in the **Merge Options** wizard page *(on page 2960)* will be selected automatically (and you cannot change this).

General Merge Recommendations

As a recommendation, you should only merge into clean working copies that **do not** contain any of the following:

- Modifications.
- Sparse directories (all directories must be of depth *infinity*).
- Switched items.

Important:
This recommendation becomes mandatory when performing a *reintegrate merge (on page 2955)* operation. Also, trying to merge to mixed-revision working copies will fail in all types of merge operations.

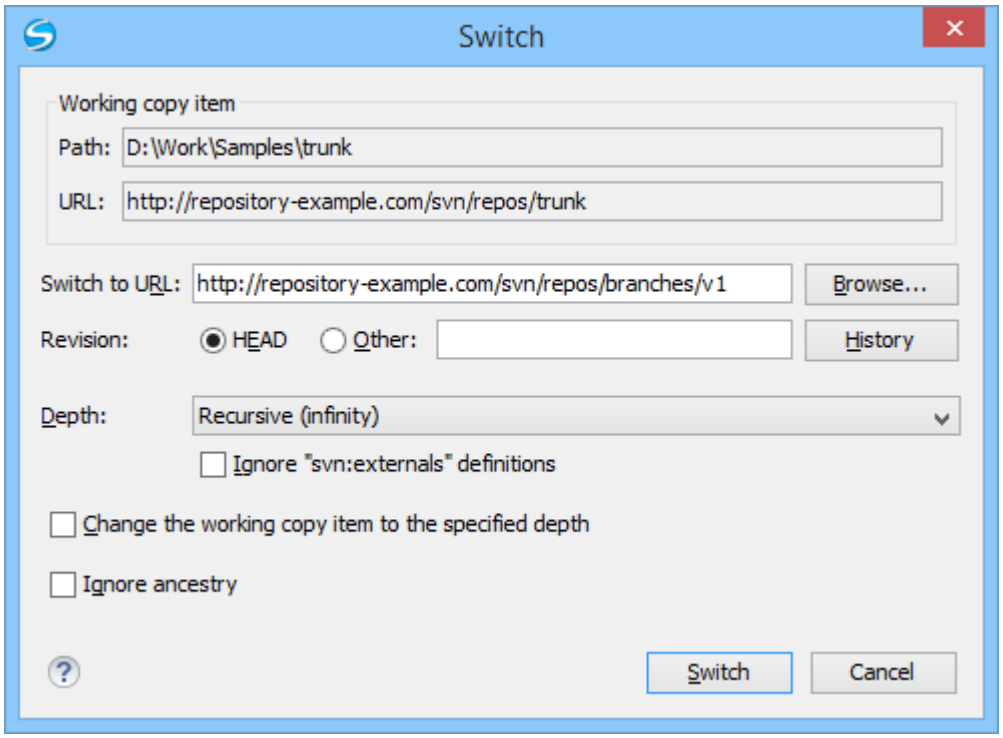
Remember:
The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Switch the Repository Location

The **Switch** action is useful when the repository location of a working copy, or an already committed item in the working copy, must be changed within the same repository. The action is available on the **Tools** menu when a versioned resource is selected in the current working copy that is displayed in the **Working Copy** view *(on page 2990)*.

Note:
External items cannot be switched using this action. Instead, change the value of the `svn:externals` property set on the parent directory of the external item and update the parent directory.

Figure 726. Switch Dialog Box



The following options can be configured in the **Switch** dialog box:

Switch to URL

The new location in the same repository *(on page 3025)* you are switching to.

> **Tip:**
> You can switch to items that were deleted, moved, or replaced, by specifying the original URL (before the item was removed) and use a *peg* revision *(on page 3027)* at the end (for example, `URL@rev1234`).

> **Note:**
> For items that are already *switched (on page 2992)* that you want to switch back, the proposed URL is the original location of the item.

Revision

The specific version of the location that you are switching to.

Depth - (This option is applicable only for directories)

Current depth

Obeys the depths registered for the directories in the working copy that are to be switched.

Recursive (infinity)

Switches the location of the selected folder and all of its files and folders.

Immediate children (immediates)

Switches the location of the selected folder and its child files and folders without recursing subfolders.

File children only (files)

Switches the location of the selected folder and its child files.

This folder only (empty)

Switches the location of the selected folder (no child files or folders are included).

Ignore "svn:externals" definitions

When selected, external items are ignored in the switch operation. This option is only available if you choose the **Current depth** or **Recursive (infinity)** depth.

Change the working copy item to the specified depth

Changes the *sticky* depth on the directory in the working copy.

Ignore ancestry

When not selected, the SVN system does not allow you to switch to a location that does not share a common ancestry with the current location. If selected, the SVN does not check for a common ancestry.

Relocate a Working Copy

Sometimes the base URL of the repository is changed after a working copy is checked out from that URL. For example, if the repository itself is moved to a different server. In such cases, you do not have to check out a working copy from the new repository location. It is easier to change the base URL of the root folder of the working copy to the new URL of the repository *(on page 3025)*.

Note:
Peg revisions have no effect for this operation.

This **Relocate** action is available in the **Tools** menu when selecting the root item of the working copy.

Note:
External items that are defined using absolute URLs and that point to the same repository as the working copy are not affected by the **Relocate** action (the URL is not updated). To relocate these items, change the value of the `svn:externals` property for each external item (set on their parent directories). For example, if an external item is defined as `externalDir http://host/path/to/repo/to/dir` and the repository was moved to another server (`host2`) and its protocol changed to `https`, then the value of the property needs to be updated to `externalDir https://host2/path/to/repo/to/dir`.

Tip:
If you edit external items using the method described in the previous note, on the next update the system will try to fetch the external items again. To avoid this, you can invoke the **Relocate** action on each of these external items.

Patches

This section explains how to work with patches in Syncro SVN Client.

What is a Patch

Suppose you are working with a set of XML files that you want to tag the project and distribute releases to other team members. While working on the project and correcting problems, you may need to distribute the corrections to other team members. In this case, you can distribute a patch (a collection of differences) that would correct the problems when applied over the last distribution. By default, the Syncro SVN Client generates patches in the Unified Diff format, but it can also use the *Git* format *(on page 2978)*.

Creating a patch in Apache Subversion™ implies the access to either two revisions of a versioned item, or two different versioned items from the repository:

- *Two revisions of a version item* - the item can be local or remote and you can select two versions of it. This also applies when you need to generate a patch that only contains the changes in the working copy that were not yet committed.
- *Two different versioned items from the repository* - the items are remote and you need to specify a revision for both.

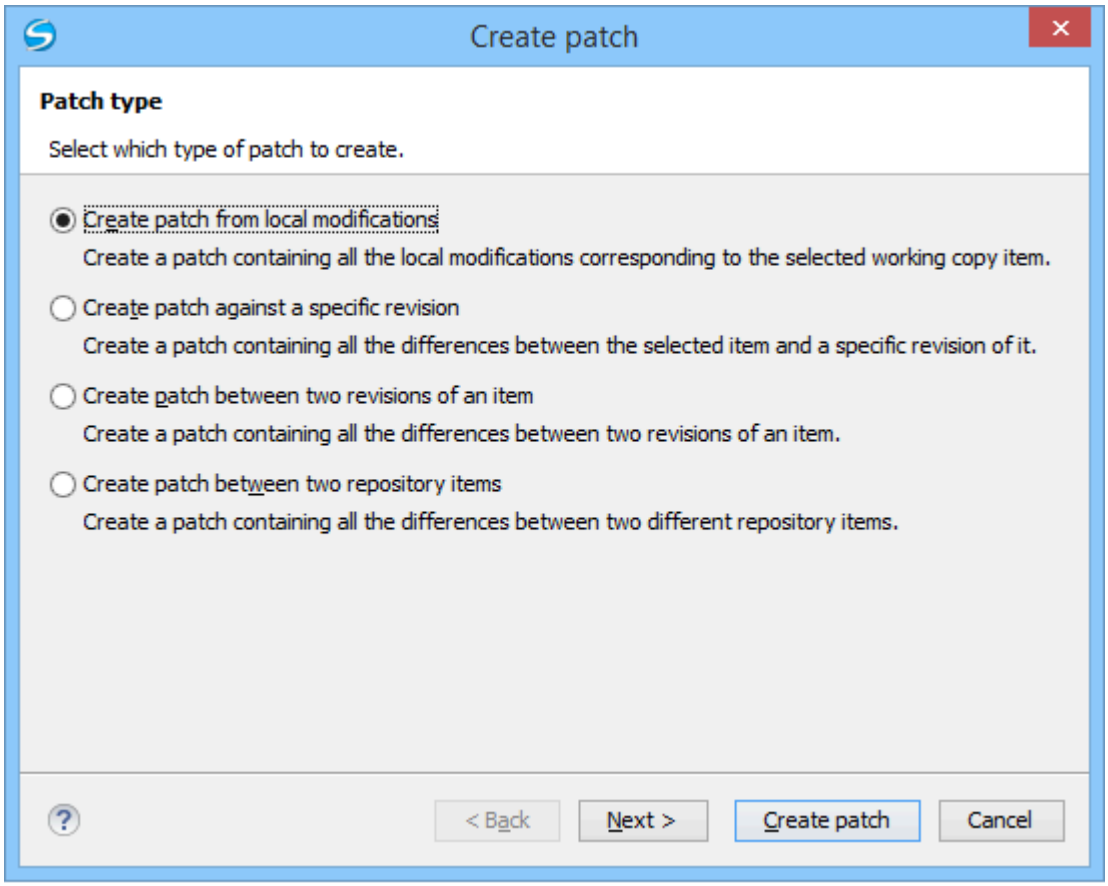
Warning:
The resulting patch file may contain content that was written using a mix of encodings, based upon the encodings of the files that were compared. If you open the generated patch file in a text editor, it may result in unrecognizable content.

Generating a Patch - Local Items

Based on a versioned item (already committed or scheduled for addition) in the working copy, you can generate patches that contain the local changes, the differences between a specific revision of that item and the item itself, or differences between the pristine item and another item from the repository. There are four options for generating a patch based upon local items.

To open the **Create patch** wizard, use the **Create patch** action from the **Tools** menu or from the contextual menu in the **Modified**, **Incoming**, **Outgoing**, or **Conflicts** modes.

Figure 727. Create Patch Wizard - Local Items



Create Patch from Local Modifications

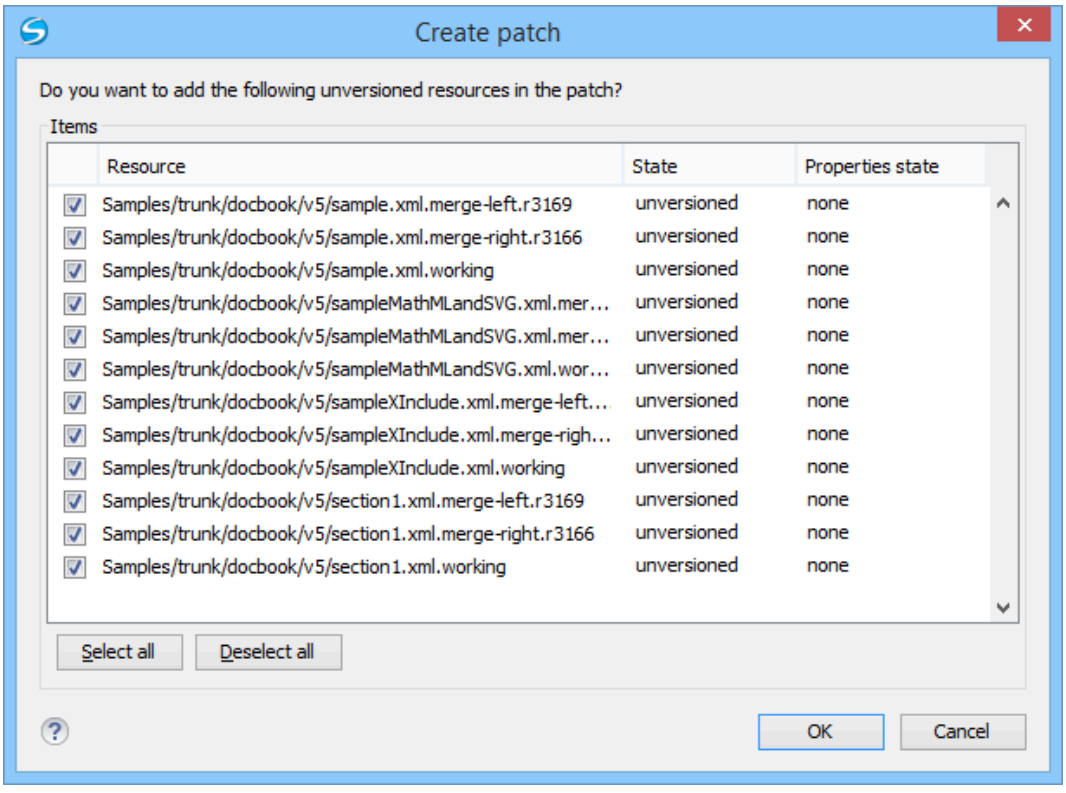
This is the most commonly used type of patch and contains only the local changes for the selected item.

This option is useful if you want to share changes with other team members and you are not yet ready to commit them. This option is only available for local items that contain modifications. It is not available for items that have a local file status of *unversioned* or *ignored*, and in some cases *missing* or *obstructed (on page 2992)*.

The steps are as follows:

1. Go to menu **Tools > Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch from local modifications** option in the dialog box.
3. Optionally, if you want to configure the options *(on page 2976)* for your patch, click the **Next** button.
   This options page does not remember your selections when creating future patches. It will revert to the default values.
   The **Options** wizard page is displayed.
4. Click the **Create patch** button.
   If the patch is applied on a folder of the working copy and that folder contains *unversioned* files *(on page 2992)*, this step of the wizard offers the option of selecting the ones that will be included in the patch.

Figure 728. Create Patch Dialog Box - Add Unversioned Resources



The patch is created and stored in the path specified in the **Output** section of the **Options** page *(on page 2976)* or in the default location.

Create Patch Against a Specific Revision

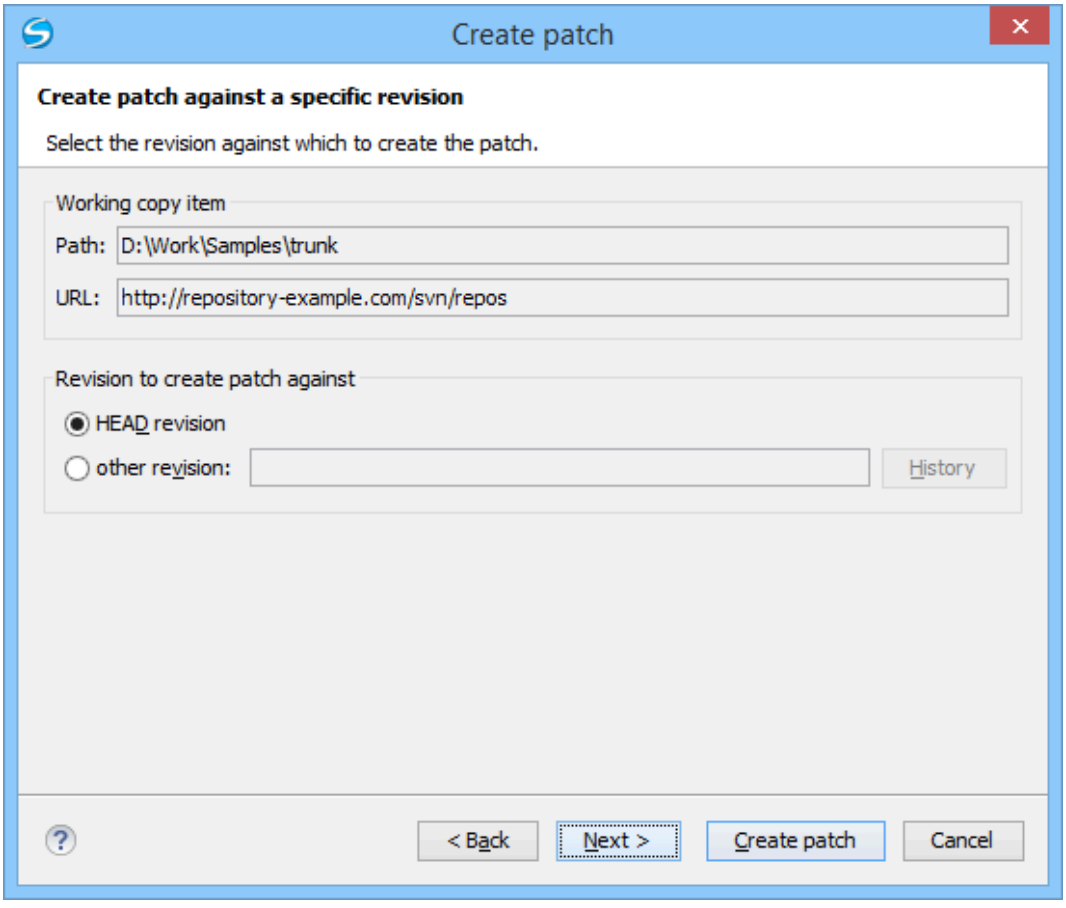
This type of patch contains changes between an old revision and the current content from the selected item within the working copy.

This option is useful if you want to obtain differences between an older revision and the current state of the working copy (for instance, to test how current changes apply to an older version).

The steps are as follows:

1. Go to menu **Tools > Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch against a specific revision** option in the dialog box.
3. Click the **Next** button.
   The second step of the wizard is opened:

Figure 729. Create Patch Wizard - Step 2



4. Select the **revision to create patch against**.
   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can click the **History** button *(on page 2918)* to display a list of the item revisions.

> **Note:**
> If the **revision to create patch against** is older than the revision that the working copy item was updated for, the patch will include changes that were made **after** the selected revision.

5. Optionally, if you want to configure the options *(on page 2976)* for your patch, click the **Next** button.
   This options page does not remember your selections when creating future patches. It will revert to the default values.
   The **Options** wizard page is displayed.
6. Click the **Create patch** button.
   The patch is created and stored in the path specified in the **Output** section of the **Options** page *(on page 2976)* or in the default location.

Create Patch Between Two Revisions of an Item

This type of patch contains historical changes between two revisions of a selected item.

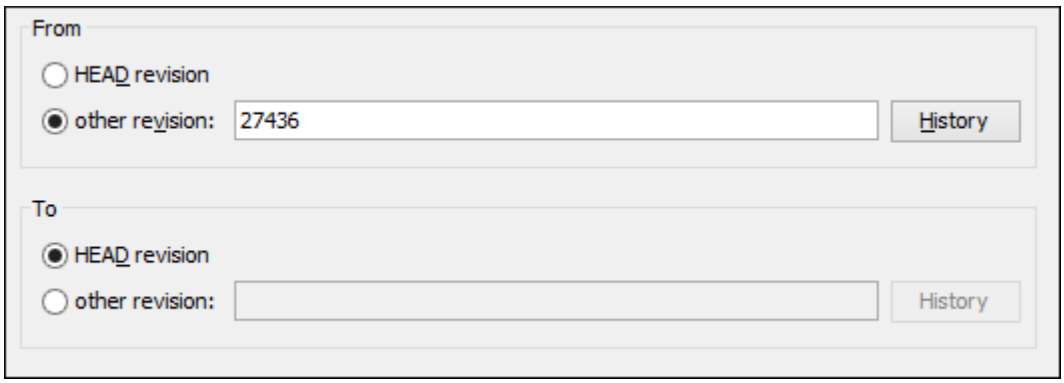
This option is useful if you want to share changes between two revisions with other team members.

> **Tip:**
> If you need to generate a patch between two revisions of a previously *deleted*, *moved*, or *replaced* item, you should use the **Create patch between two repository items** option *(on page 2971)* instead.

The steps are as follows:

1. Go to menu **Tools > Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch between two revisions of an item** option in the dialog box.
3. Click the **Next** button.
   The second step of the wizard is opened:

Figure 730. Create Patch Wizard - Step 2



4. Select the starting and ending revisions in the **From** and **To** sections.
   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can click the **History** button *(on page 2918)* to display a list of the item revisions.

Note:
The patch will only include changes between the two specified revisions, starting with the changes that were made **after** the older revision.

Tip:
If you want to reverse changes done between two revisions by using a patch file, you can specify the newer revision in the **From** section and the older version in the **To** section.

5. Optionally, if you want to configure the options *(on page 2976)* for your patch, click the **Next** button.
   This options page does not remember your selections when creating future patches. It will revert to the default values.
   The **Options** wizard page is displayed.
6. Click the **Create patch** button.
   The patch is created and stored in the path specified in the **Output** section of the **Options** page *(on page 2976)* or in the default location.

Create Patch Between Two Repository Items

This type of patch contains changes between one version of an item and a specific version of another item.

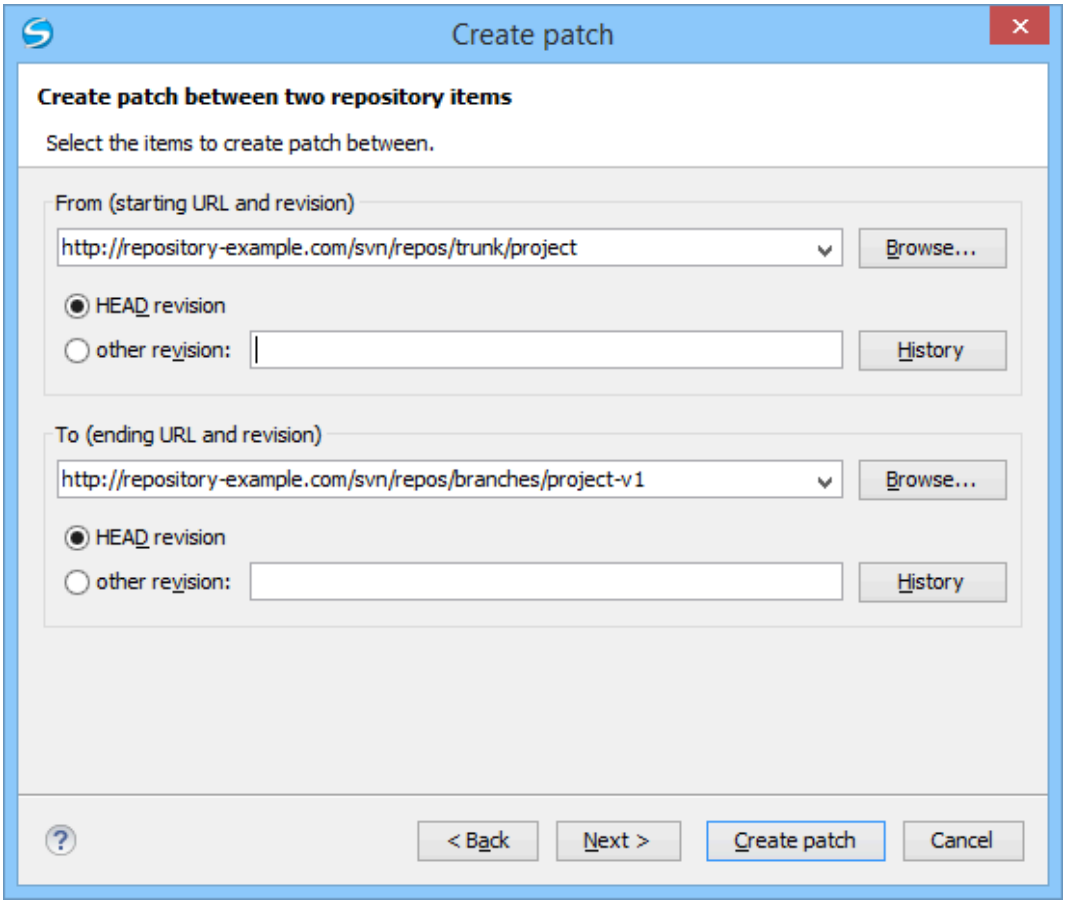
This option is useful for generating a patch that contains changes between existing, or even previously deleted, moved, or replaced items from different branches. This is the default option when you do not have a working copy loaded, when no repository items are selected, or when exactly two repository items of the same kind are selected.

Tip:
To access an item that was deleted, moved, or replaced, you need to specify the original URL (before the item was removed) and use a *peg* revision *(on page 3027)* at the end (for example, `URL@rev1234`).

The steps are as follows:

1. Go to menu **Tools > Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch between two repository items** option in the dialog box.
3. Click the **Next** button.
   The second step of the wizard is opened:

Figure 731. Create Patch Wizard - Step 2



4. Select the starting and ending URLs *(on page 3025)* and revisions in the **From** and **To** sections.
   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can click the **History** button *(on page 2918)* to display a list of the item revisions.

   Important:
   Both URLs must point to items from the same repository.

   Note:
   If you use a *peg* revision in the URL field, anything specified in the **other revision** field is ignored.

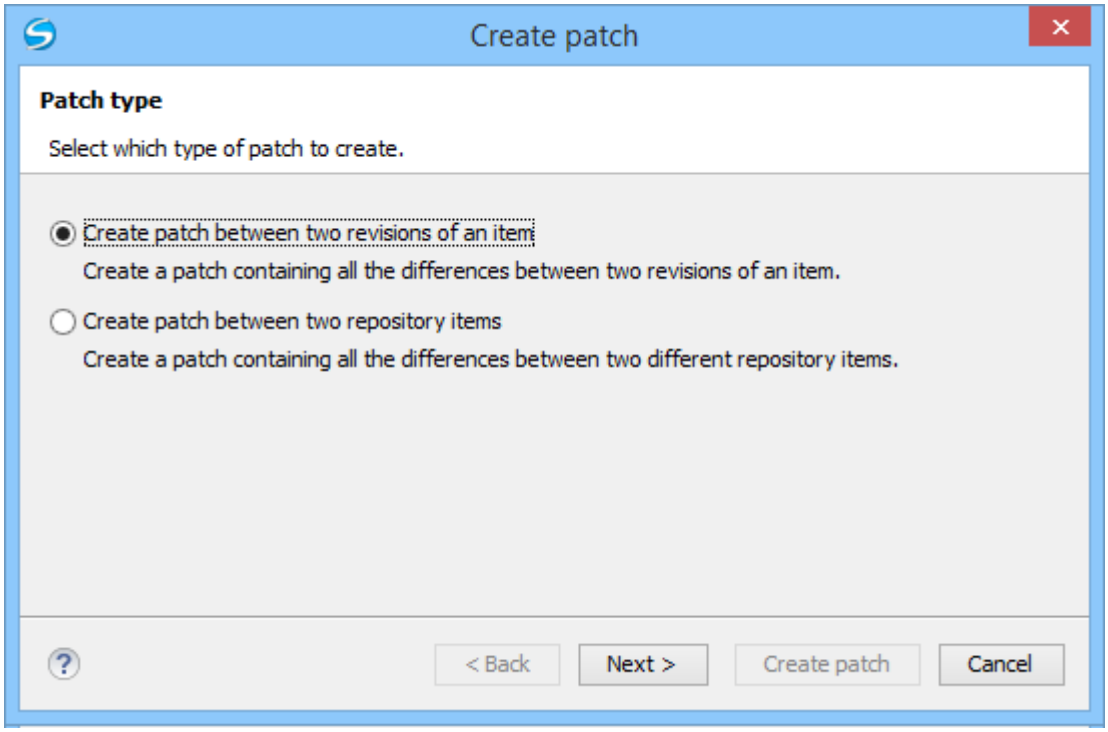
5. Optionally, if you want to configure the options *(on page 2976)* for your patch, click the **Next** button.
   This options page does not remember your selections when creating future patches. It will revert to the default values.
   The **Options** wizard page is displayed.
6. Click the **Create patch** button.
   The patch is created and stored in the path specified in the **Output** section of the **Options** page *(on page 2976)* or in the default location.

Generating a Patch - Remote Items

Based on a repository item, you can generate patches that contain the differences between two specific revisions of that item, or between a revision of that same item and another revision of another item from the repository. There are two options for generating a patch based upon remote items.

To open the **Create patch** wizard, use the **Create patch** action from the **Tools** menu.

Figure 732. Create Patch Wizard - Remote Items



Create Patch Between Two Revisions of an Item

This type of patch contains historical changes between two revisions of a selected item.

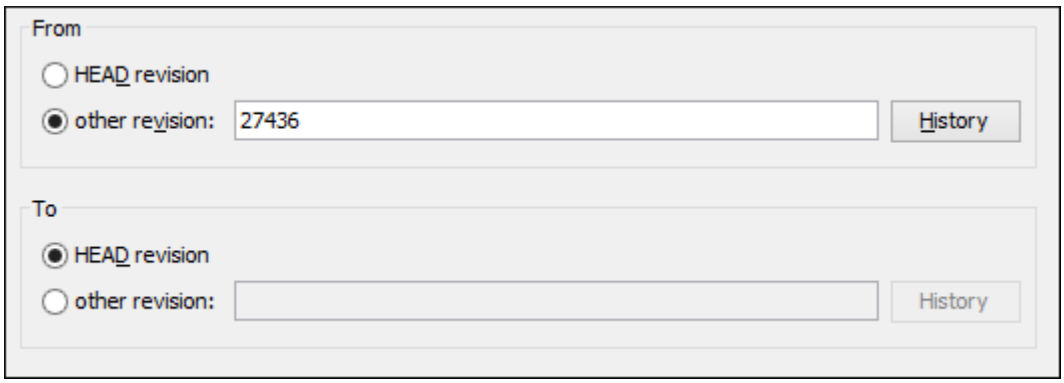
This option is useful if you want to share changes between two revisions with other team members.

Tip:
If you need to generate a patch between two revisions of a previously *deleted*, *moved*, or *replaced* item, you should use the **Create patch between two repository items** option *(on page 2971)* instead.

The steps are as follows:

1. Go to menu **Tools > Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch between two revisions of an item** option in the dialog box.
3. Click the **Next** button.
   The second step of the wizard is opened:

Figure 733. Create Patch Wizard - Step 2



4. Select the starting and ending revisions in the **From** and **To** sections.
   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can click the **History** button *(on page 2918)* to display a list of the item revisions.

   Note:
   The patch will only include changes between the two specified revisions, starting with the changes that were made **after** the older revision.

   Tip:
   If you want to reverse changes done between two revisions by using a patch file, you can specify the newer revision in the **From** section and the older version in the **To** section.

5. Optionally, if you want to configure the options *(on page 2976)* for your patch, click the **Next** button.
   This options page does not remember your selections when creating future patches. It will revert to the default values.
   The **Options** wizard page is displayed.
6. Click the **Create patch** button.
   The patch is created and stored in the path specified in the **Output** section of the **Options** page *(on page 2976)* or in the default location.

Create Patch Between Two Repository Items

This type of patch contains changes between one version of an item and a specific version of another item.

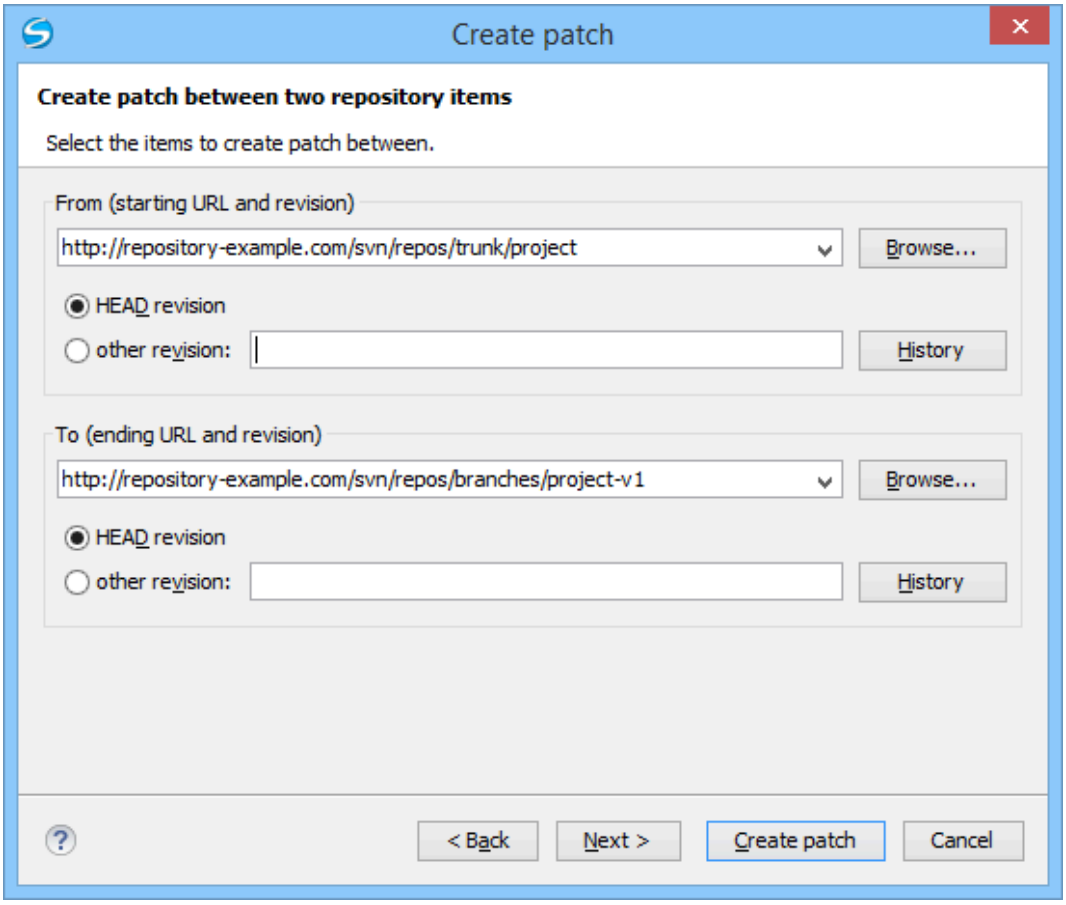
This option is useful for generating a patch that contains changes between existing, or even previously deleted, moved, or replaced items from different branches. This is the default option when you do not have a working copy loaded, when no repository items are selected, or when exactly two repository items of the same kind are selected.

Tip:
To access an item that was deleted, moved, or replaced, you need to specify the original URL (before the item was removed) and use a *peg revision (on page 3027)* at the end (for example, `URL@rev1234`).

The steps are as follows:

1. Go to menu **Tools > Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch between two repository items** option in the dialog box.
3. Click the **Next** button.
   The second step of the wizard is opened:

Figure 734. Create Patch Wizard - Step 2



4. Select the starting and ending URLs *(on page 3025)* and revisions in the **From** and **To** sections.
   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can click the **History** button *(on page 2918)* to display a list of the item revisions.

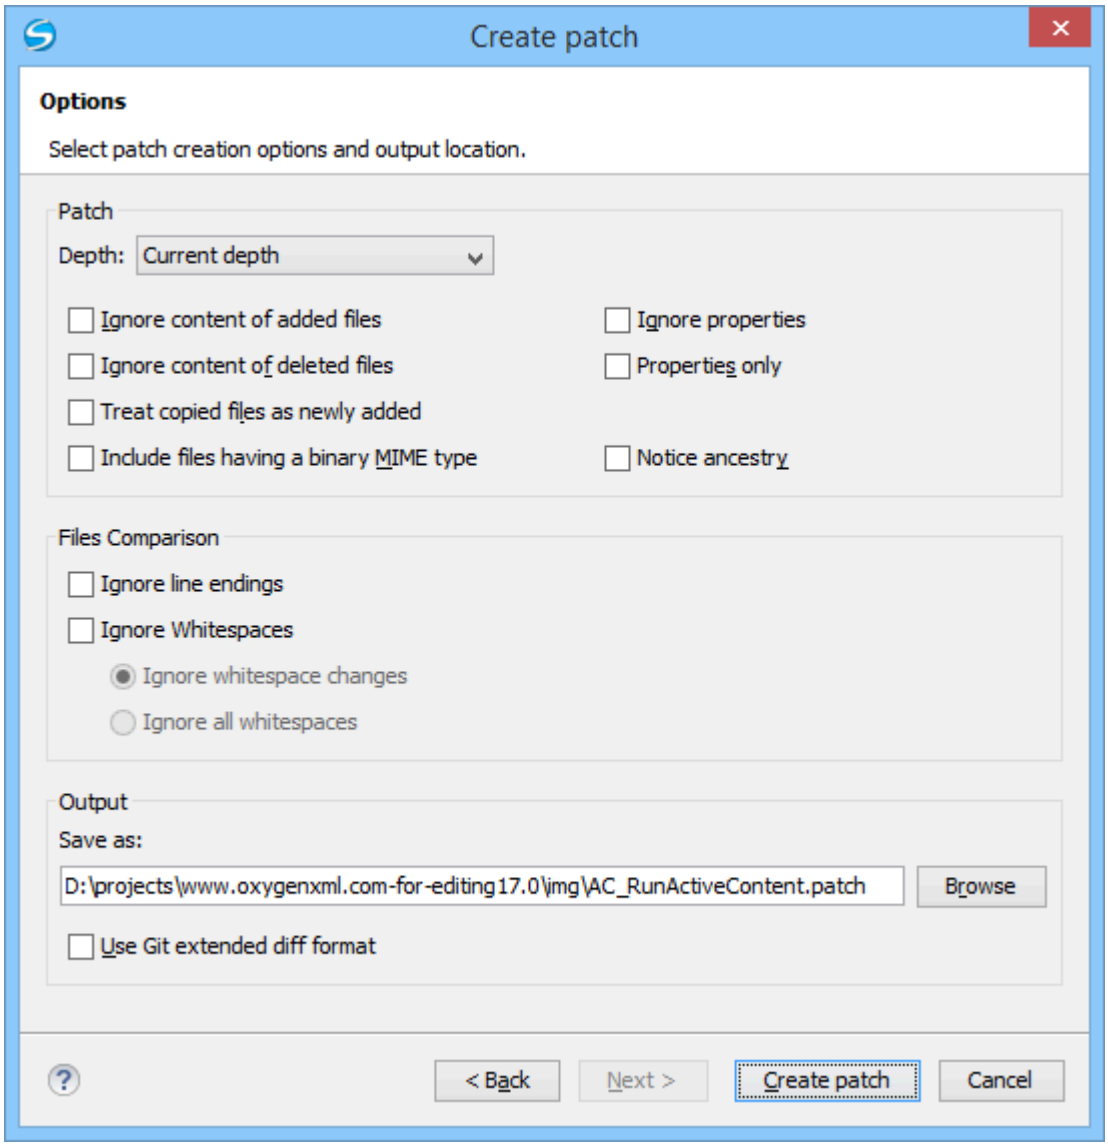
Important:
Both URLs must point to items from the same repository.

Note:
If you use a *peg* revision in the URL field, anything specified in the **other revision** field is ignored.

5. Optionally, if you want to configure the options *(on page 2976)* for your patch, click the **Next** button.
   This options page does not remember your selections when creating future patches. It will revert to the default values.
   The **Options** wizard page is displayed.
6. Click the **Create patch** button.
   The patch is created and stored in the path specified in the **Output** section of the **Options** page *(on page 2976)* or in the default location.

Patch Options

Figure 735. Create Patch Wizard - Options



Patch Section

Depth - (This option is applicable only for directories)

Current depth

The depth of recursing the folder for creating the patch is the same as the depth of that same folder in the working copy (available only when generating patches that contain changes from the working copy).

Recursive (infinity)

The patch is created on all the files and folders contained in the selected folder.

Immediate children (immediates)

The patch is created only on the child files and folders without recursing subfolders.

File children only (files)

The patch is created only on the child files.

This folder only (empty)

The patch is created only on the selected folder (no child file or folder is included in the patch).

Ignore content of added files

When selected, the patch file does not include the content of the *added* items. This option corresponds to the `--no-diff-added` option of the `svn diff` command.

Ignore content of delete files

When selected, the patch file does not include the content of the *deleted* items. This option corresponds to the `--no-diff-deleted` option of the `svn diff` command.

Treat copied files as newly added

When selected, copied items are treated as new, rather than comparing the items with their sources. This option corresponds to the `--show-copies-as-adds` option of the `svn diff` command.

Include files having a binary MIME type

When selected, the application is forced to compare items that are considered binary file types. This option corresponds to the `--force` option of the `svn diff` command.

Ignore properties

When selected, differences in the properties of items are ignored. This option corresponds to the `--ignore-properties` option of the `svn diff` command.

Properties only

When selected, only differences in the properties of the items are included in the patch file (file content is ignored). This option corresponds to the `--properties-only` option of the `svn diff` command.

Note:
The **Ignore properties** and **Properties only** options are mutually exclusive.

Notice ancestry

If selected, the SVN common ancestry is taken into consideration when calculating the differences. This option corresponds to the `--notice-ancestry` option of the `svn diff` command.

Files Comparison Section

Ignore line endings

If selected, the differences in line endings are ignored when the patch is generated. This option corresponds to the `--ignore-eol-style` option of the `svn diff` command.

Ignore whitespaces

If selected, it allows you to specify how the whitespace changes should be handled. When selected, you can then choose between two options:

- **Ignore whitespace changes** (`--ignore-space-change`) - Ignores changes in the amount of whitespaces or changes to their type (for example, when changing the indentation or changing tabs to spaces).

  Note:
  Whitespaces that are added or removed are still considered to be changes.

- **Ignore all whitespaces** (`--ignore-all-space`) - Ignores all types of whitespace changes.

Output Section

Save as

The patch will be created and saved in the specified file.

Use Git extended diff format

When selected, the patch is generated using the *Git* format. This option corresponds to the `--git` option of the `svn diff` command.

Working with Repositories

This section explains how to locate and browse SVN repositories in Syncro SVN Client.

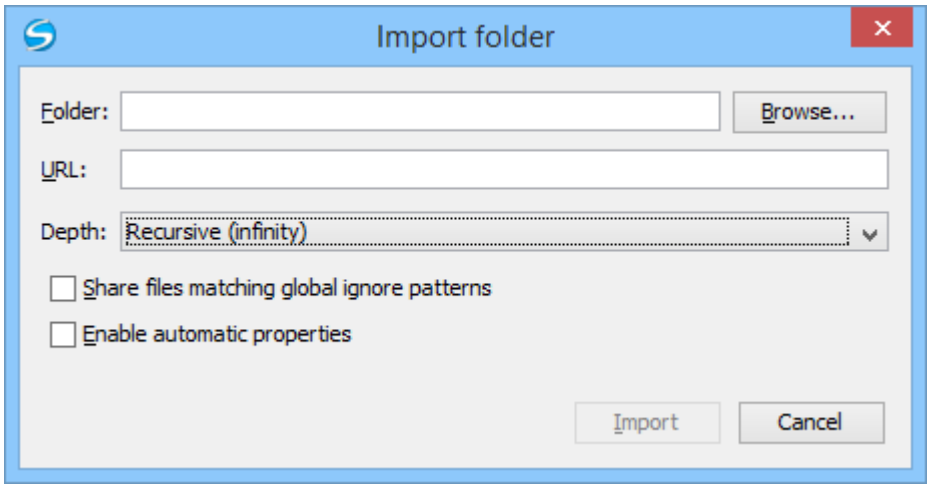
Importing Resources Into a Repository

Importing resources into a repository is the process of copying local files and directories into a repository so that they can be managed by an Apache Subversion™ server. If you have already been using Subversion and you have an existing working copy you want to use, then you will likely want to follow the procedure for using an existing working copy *(on page 2919)*.

The **Import folder** and **Import Files** actions are available from the **Import** submenu of the **Repository** menu or of the contextual menu in the **Repositories** view. These actions open a dialog box that allow you to select the directories or files that will be imported into the selected repository location.

The **Import folder** action opens the **Import folder** dialog box.

Figure 736. Import Folder Dialog Box



You can configure the following options:

Folder

Specify the local folder *(on page 3025)* by using the text box or the **Browse** button. This folder should not be empty or already under version control.

> **Important:**
> By default, the SVN system only imports the content of the specified folder, and not the folder itself. Therefore, it is recommended to use the **Browse** button to select the local folder so that the client will automatically append the name of it to the specified URL.

URL

Specify the repository location *(on page 3025)* that will be used to access the folder to be imported.

> **Note:**
> *Peg revisions* have no effect for this operation since it is used to send information to the repository.

Attention:
If the new location already exists, make sure that it is an empty directory to avoid mixing your project content with other files (if items exist with the same name, an error will occur and the operation will not proceed). Otherwise, if the address does not exist, it is created automatically.

Depth

Recursive (infinity)

Imports all the files and folders contained in the selected folder.

Immediate children (immediates)

Imports only the child files and folders without recursing subfolders.

File children only (files)

Imports only the child files.

This folder only (empty)

Imports only the selected folder (no child file or folder is included).

Share files matching global ignore patterns

When selected, the file names that match the patterns defined in either of the following locations are also imported into the repository:

- The `global-ignores` property in the SVN configuration file *(on page 3025)*.
- The **File name ignore patterns** option *(on page 293)* in the **SVN > Working Copy** preferences page *(on page 292)*.

Enable automatic properties/Disable automatic properties

Enables or disables automatic property assignment (per runtime configuration rules), overriding the `enable-auto-props` runtime configuration directive, defined in the SVN configuration file *(on page 3025)*.

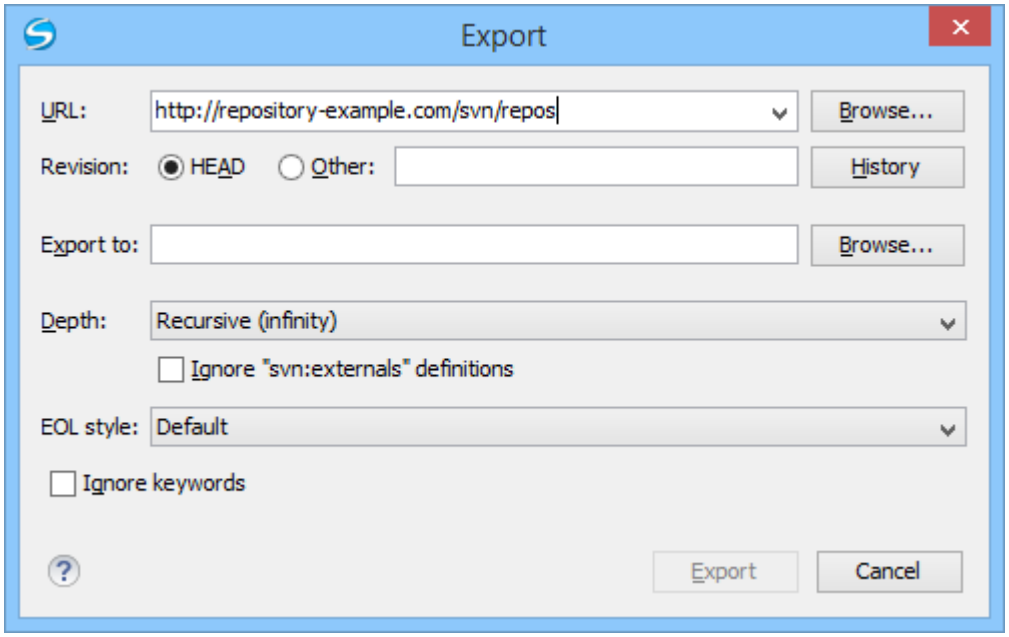
Note:
This option is available only when there are defined properties to be applied automatically for newly added items under version control. You can define these properties in the SVN `config` file (in the `auto-props` section). Based on the value of the `enable-auto-props` runtime configuration directive, the presented option is either **Enable automatic properties**, or **Disable automatic properties**.

Exporting Resources From a Repository

This is the process of taking a resource from the repository and saving it locally in a clean form, with no version control information. This is very useful when you need a clean build for an installation kit.

The **Export** dialog box is similar to the **Check out** dialog box:

Figure 737. Export from Repository Dialog Box



You can configure the following options:

URL

Specify the source directory from the repository *(on page 3025)* by using the text box or the **Browse** button.

Tip:
To export an item that was deleted, moved, or replaced, you need to specify the original URL (before the item was removed) and use a *peg* revision *(on page 3027)* at the end (for example, `URL@rev1234`).

Note:
The content of the selected directory from the repository and not the directory itself will be exported to the file system.

Revision

You can choose between the **HEAD** or **Other** revision. If you need to export a specific revision, specify it in the **Other** text box or use the **History** button and choose a revision from the **History** dialog box.

Export to

Specify the location where you want to export *(on page 3025)* the repository directory by typing the local path in the text box or by using the **Browse** button. If the specified local path does not point to an existing directory, it will automatically be created.

Important:
By default, the SVN system only exports the content of the directory specified by the URL, and not the directory itself. Therefore, it is recommended to use the **Browse** button to select the *export* location so that the client will automatically append the name of the remote directory to the path of the selected directory.

Warning:
The destination directory should be empty. If files exist, they will be overwritten by exported files with matching names.

Depth

Recursive (infinity)

Exports all the files and folders contained in the selected folder.

Immediate children (immediates)

Exports only the child files and folders without recursing subfolders.

File children only (files)

Exports only the child files.

This folder only (empty)

Exports only the selected folder (no child file or folder is included).

Ignore "svn:externals" definitions

When selected, external items are ignored in the export operation. This option is only available if you choose the **Recursive (infinity)** depth.

EOL style

Defines the *end-of-line (EOL)* marker that should be used when exporting files that have the value or the `svn:eol-style` property set to `native`. You can choose between the following styles:

- **Default** - It uses the system-specific *end-of-line* marker.
- **CRLF** - The Windows-specific *end-of-line* marker (*carriage return - line feed*).
- **LF** - The Unix / macOS-specific *end-of-line* marker (*line feed*).
- **CR** - The macOS 9 (or older)-specific *end-of-line* marker (*carriage return*).

Ignore keywords

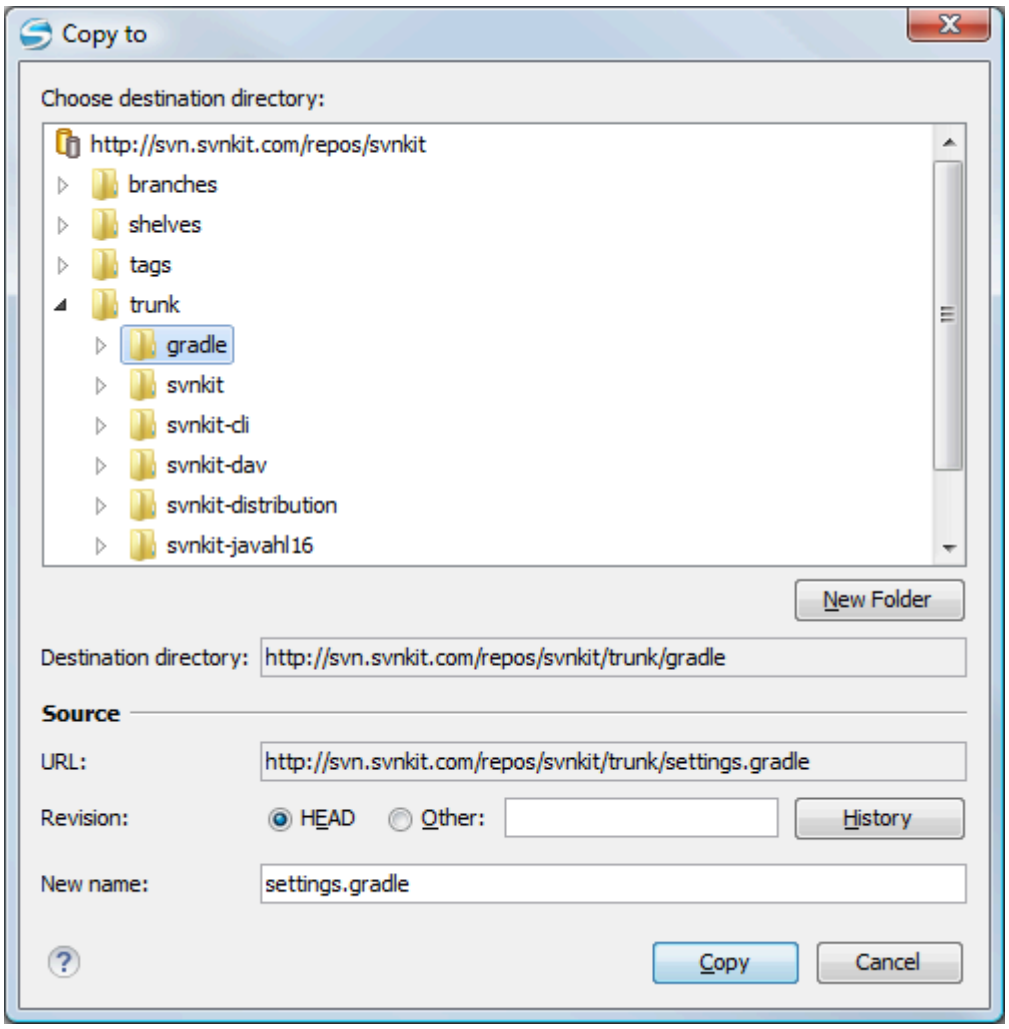
When selected, the export operation does not expand the *SVN keywords* found inside the files.

Copy / Move / Delete Resources From a Repository

Once you have a location defined in the **Repositories** view *(on page 2985)*, you can run commands (such as copy, move, and delete) directly on the repository. The commands correspond to the following actions in the contextual menu:

The **Copy to** and **Move to** action allows you to copy and move individual or multiple resources to a specific directory from the *HEAD* revision of the repository.

Figure 738. Copy/Move Items in Repository



The dialog box used to copy or move items allows you to browse the *HEAD* revision of the repository and select the destination of the items, presenting its repository URL below the tree view.

The **Source** section presents relevant options regarding the item(s) that you move or copy:

- **URL** - This field is displayed only if you copy/move a single item.
- **Revision** - Presents the revision that will have one or more items copied, allowing you to also choose another revision.

Note:
Since only items from the HEAD revision can be moved, the **Revision** options are not presented for the **Move to** action.

Note:
When you copy a single item while browsing a revision other than *HEAD*, the **Revision** options present this revision but does not allow you to change it. The same applies if copying multiple items.

- **New name** - This option is presented when you copy or move a single item, allowing you to also rename it.

Another useful action is **Delete**, allowing you to erase resources directly from the repository.

All three actions are commit operations and you will be prompted with the **Commit message** dialog box.

Sparse Checkout

Sometimes you only need to check out certain parts of a directory tree. In this case, you can check out the top directory (using the**Check out** action from the **Repositories** view *(on page 2986)*) and then recursively update only the needed directories (using the **Update** action from the **Working Copy** view *(on page 2998)*). Each directory then has a depth set to it, with four possible values:

- **Recursive (infinity)** - Updates all descendant directories and files recursively.
- **Immediate children (immediates)** - Updates the directory, including direct child directories and files, but does not populate the child directories.
- **File children only (files)** - Updates the directory, including only child files without the child directories.
- **This folder only (empty)** - Updates only the selected directory, without updating any children.

For some operations, you can use as depth the current depth registered on the directories from the working copy (the value **Current depth**). This is the depth value defined in a previous check out or update operation.

The sparse checked out directories are presented in the **Working Copy** view *(on page 2990)* with a marker corresponding to each depth value, in the top left corner, as follows:

- **Recursive (infinity)** - This is the default value and it is has no mark. The directory has no limiting depth.
- **Immediate children (immediates)** - The directory is limited to direct child directories (without contents) and files.
- **File children only (files)** - The directory is limited to direct child files only.
- **This folder only (empty)** - The directory has *empty* depth set.

A depth set on a directory means that some operations process only items within the specified depth range. For example, **Synchronize** on a working copy directory reports the repository modified items within the depth set on the directory and those existing in the working copy outside of this depth.

The depth information is also presented in the **SVN Information** dialog box and in the tooltip displayed when hovering a directory in the **Working Copy** view.

Syncro SVN Client Views

The main working area occupies the center of the application window, which contains the most important views:

- Repositories View *(on page 2985)*
- Working Copy View *(on page 2990)*
- History View *(on page 3005)*
- Console View *(on page 3020)*

The other views that support the main working area are also presented in this section.

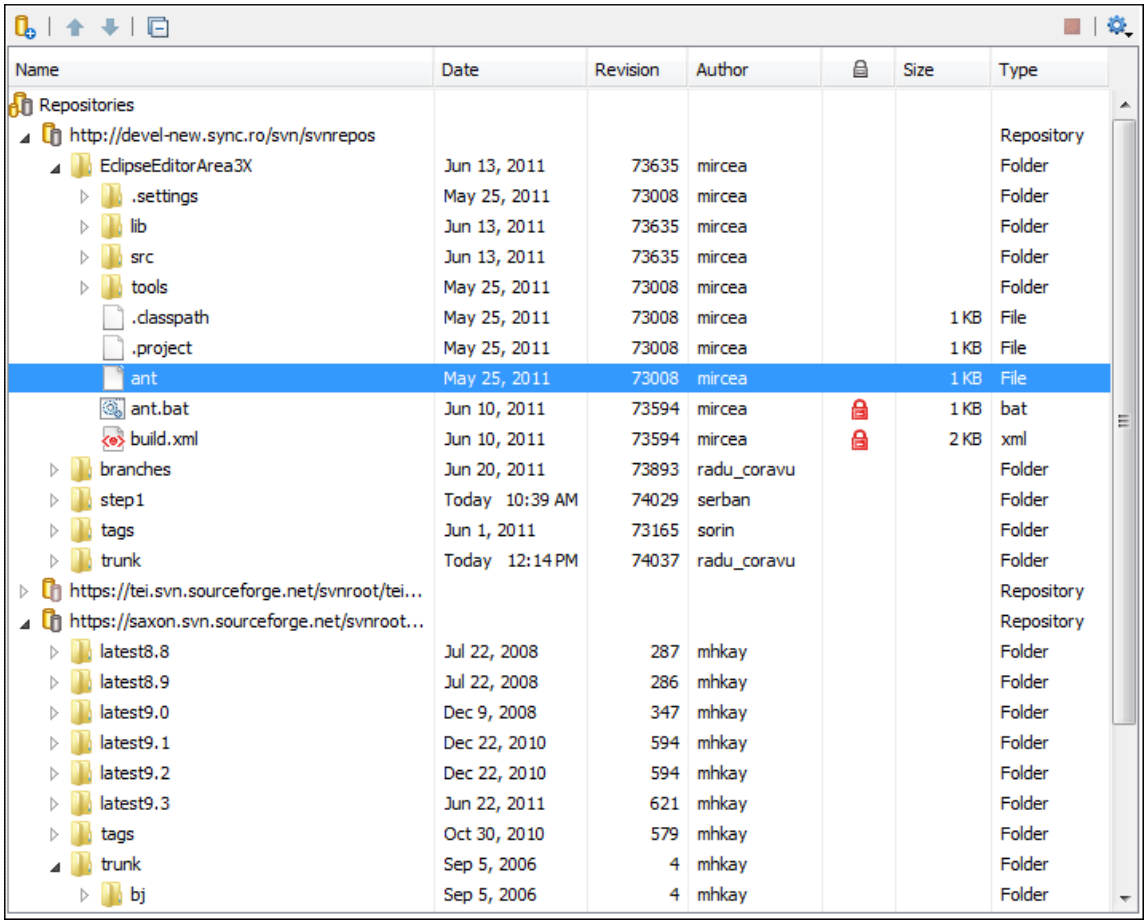
Repositories View

The **Repositories** view allows you to define and manage Apache Subversion™ repository locations and browse repositories. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

If no connections to your repository are available, you can add a new repository location *(on page 2911)*. Repository files and folders are presented in a tree view with the repository locations at the first level, where each location represents a connection to a specific repository. More information about each resource is displayed in a tabular form:

- **Date** - Date when the resource was last modified.
- **Revision** - The revision number at the time the resource was last modified.
- **Author** - Name of the person who made the last modification on the resource.
- **Size** - Resource size on disk.
- **Lock information** - Information about the lock status of a file. When a repository file is locked by a user the icon is displayed in this column. If no icon is displayed the file is not locked. The tooltip of this column displays the details about the lock:
  - **Owner** - The name of the user who created the lock.
  - **Date** - The date when the user locked the file.
  - **Expires on** - Date when the lock expires. Lock expiry policy is set in the repository options, on the server side.
  - **Comment** - The message attached when the file was locked.
- **Type** - Contains the resource type or file extension.

Figure 739. Repositories View



Toolbar

The **Repositories** view's toolbar contains the following buttons:

- **New Repository Location** - Allows you to enter a new repository location by means of the **Add SVN Repository** dialog box.
- **Move Up** - Move the selected repository up one position in the list of repositories in the **Repositories** view.
- **Move Down** - Move the selected repository down one position in the list of repositories in the **Repositories** view.
- **Collapse all** - Collapses all repository trees.
- **Stop** - Stops the current repository browsing operation executed when a repository node is expanded. This is useful when the operation takes too long or the server is not responding.
- **Settings** - Allows you to configure the resource table appearance.

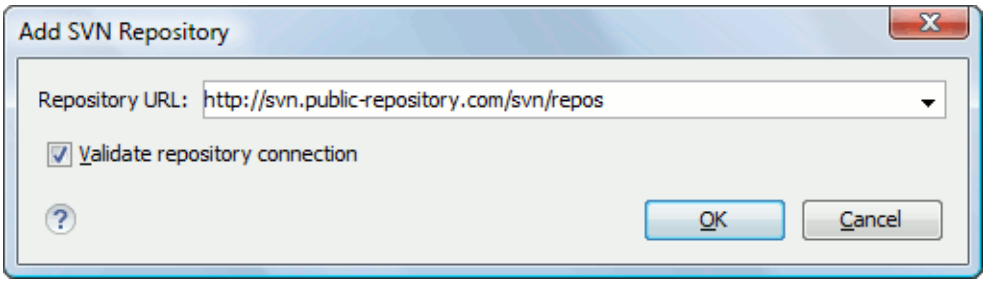
Repositories View Contextual Menu Actions

The **Repositories** view contextual menu contains various actions, depending on the selected item. If a repository location is selected, the following management actions are available:

New Repository Location (Ctrl + Alt + N (Command + Option + N on macOS))

Displays the **Add SVN Repository** dialog box. This dialog box allows you to define a new repository location.

Figure 740. Add SVN Repository Dialog Box



If the **Validate repository connection** option is selected, the URL connection is validated before being added to the **Repositories** view.

Edit Repository Location (Ctrl + Alt + E (Command + Option + E on macOS))

Context-dependent action that allows you to edit the selected repository location using the **Edit SVN Repository** dialog box. It is active only when a repository location root is selected.

Change the Revision to Browse (Ctrl + Alt + B (Command + Option + B on macOS))

Context-dependent action that allows you to change the selected repository revision using the **Change the Revision to Browse** dialog box. It is active only when a repository location root is selected.

Remove Repository Location (Ctrl + Alt + R (Command + Option + R on macOS))

Allows you to remove the selected repository location from the view. It shows you a confirmation dialog box before removal. It is active only when a repository location root is selected.

The following actions are common to all repository resources:

Open

Opens the selected file in the Editor view in read-only mode.

Open with

Displays the **Open with** dialog box to specify the editor where the selected file is opened. If multiple files are selected, only external applications can be used to open the files.

Save as

Saves the selected files locally, as they are in the browsed revision.

Refresh (F5)

Refreshes the resource selected in the **Repositories** view.

Check out (Ctrl + Alt + O (Command + Option + O on macOS))

Allows you to create a working copy from a repository directory, on your local file system. To read more about this operation, see Check out a working copy *(on page 2916)*.

Branch/Tag

Allows you to create a branch or a tag from the selected folder in the repository. To read more about how to create a branch/tag, see the Creation and management of Branches/Tags *(on page 2945)* section.

Share project

Allows you to share a new project *(on page 2914)* using an SVN repository. The local project is automatically converted into an SVN working copy.

Import:

Import folder (Ctrl + Shift + L (Command + Shift + L on macOS))

Allows you to import the contents of a specified folder from the file system into the selected folder in a repository. To read more about this operation, see the section Importing resources into a repository *(on page 2979)*.

> **Note:**
> The difference between the **Import folder** and **Share project** actions is that the latter also converts the selected directory into a working copy.

Import Files (Ctrl + Shift + I (Command + Shift + I on macOS))

Imports the files selected from the files system into the selected folder in the repository.

Export

Opens the **Export** dialog box *(on page 2980)* that allows you to configure options for exporting a folder from the repository to the local file system.

Show History (Ctrl + H (Command + T on macOS))

Displays the history of the selected resource. At the start of the operation, you can set filtering options.

Show Annotation (Ctrl + Shift + A (Command + Shift + A on macOS))

Opens the **Show Annotation** dialog box that computes the annotations for a file and displays them in the **Annotations** view *(on page 3012)*, along with the history of the file in the **History** view.

Revision Graph (Ctrl + G (Command + G on macOS))

This action allows you to see the graphical representation of a resource history. For more details about a resource revision graph see Revision Graph *(on page 3020)*. This operation is available for any resource selected in the **Repositories** view or **Working Copy** view.

Copy URL Location (Ctrl + Alt + U (Command + Option + U on macOS))

Copies to clipboard the URL location of the selected resource.

Copy to

Copies to a specified location the currently selected resource(s). This action is also available when you browse other revisions than the latest one (*HEAD*), to allow restoring previous versions of an item.

Move to (Ctrl + M (Command + M on macOS))

Moves to a specified location the currently selected resource(s).

Rename (F2)

Renames the selected resource.

Delete (Delete)

Deletes selected items from the repository via an immediate commit.

New Folder (Ctrl + Shift + F (Command + Shift + F on macOS))

Allows you to create a folder in the selected repository path (available only for folders).

Locking

The following options are available only for files:

Lock (Ctrl + K (Command + K on macOS))

Allows you to lock certain files that need exclusive access. For more details on the use of this action, see Locking a file *(on page 2927)*.

Unlock (Ctrl + Shift + K (Command + Shift + K on macOS))

Releases the exclusive access to a file from the repository. You can also choose to unlock it by force (*break the lock*).

Show SVN Properties (Ctrl + Shift + P (Command + Shift + P on macOS))

Brings up the Properties view *(on page 3018)* displaying the SVN properties for the selected resource. This view does not allow adding, editing, or removing SVN properties of a repository resource. These operations are allowed only for working copy resources.

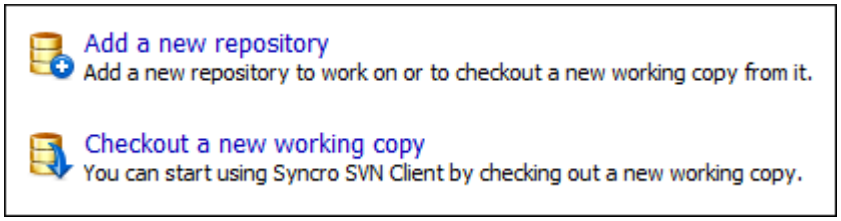
Show SVN Information (Ctrl + I (Command + I on macOS))

Provides additional information for the selected resource. For more details, go to Obtain information for a resource *(on page 2943)*.

Assistant Actions

When there is no repository configured, the **Repositories** view mode lists the following two actions:

Figure 741. Repositories View Actions



Drag and Drop Operations

The structure of the files tree can be changed with drag and drop operations inside the **Repositories** view. These operations behave in the same way with the **Copy to**/**Move to** operations.

Working Copy View

The **Working Copy** view allows you to manage the content of an SVN working copy. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

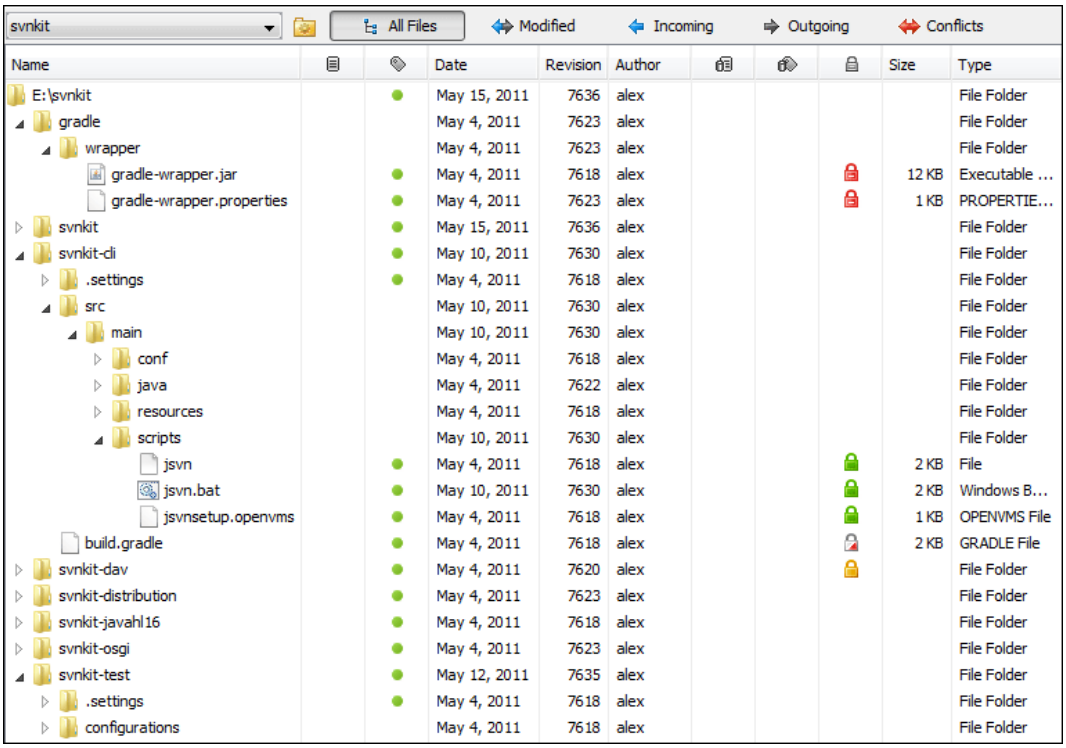
The toolbar contains the following:

- The list of defined working copies.
- A set of view modes that allow you to filter the content of the working copy based on the resource status (such as incoming or outgoing changes).
- **Settings** menu.

If you click any of the view modes (**All Files**, **Modified**, **Incoming**, **Outgoing**, **Conflicts**), the information displayed changes as follows:

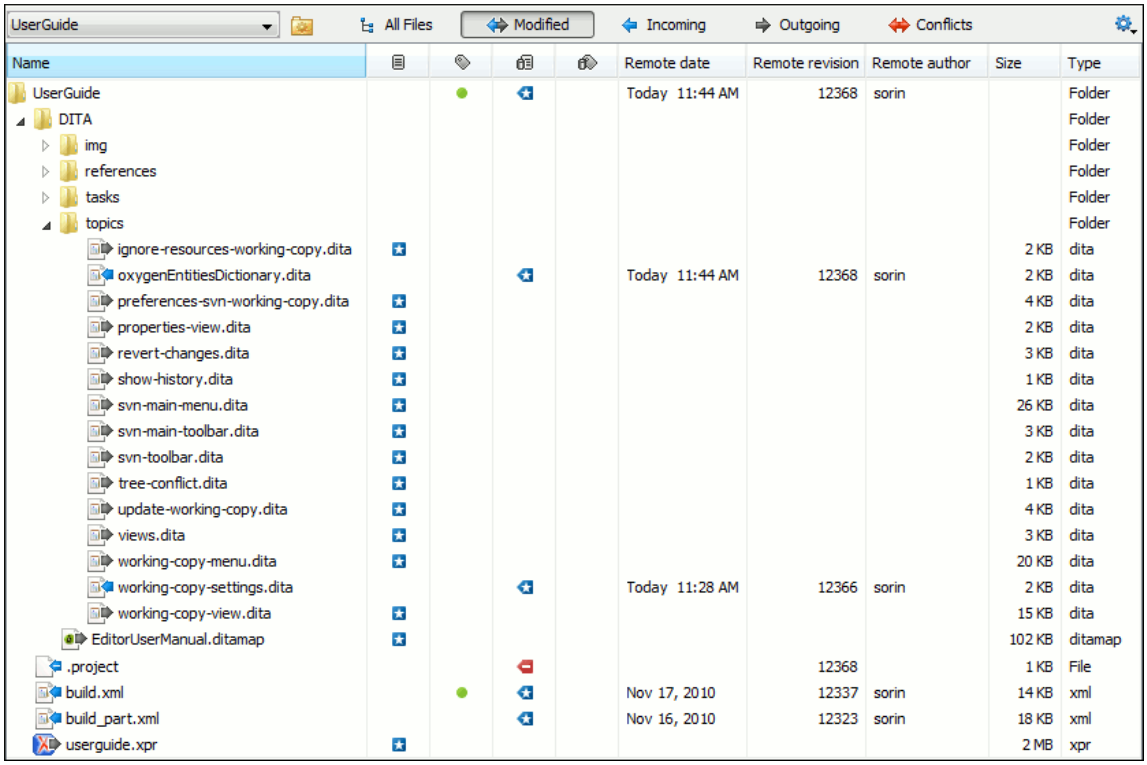
- **All Files** - Resources (files and folders) are presented in a hierarchical structure with the root of the tree representing the location of the working copy on the file system. Each resource has an icon representation that describes the type of resource and also depicts the state of that resource with a small overlay icon.

Figure 742. Working Copy View - All Files View Mode



- **Modified** - The resource tree presents resources modified locally (including those with conflicting content) and remotely. Decorator icons are used to differentiate between various resource states:
  - Incoming modification from repository:
    - - File content or properties modified remotely.
    - - New file added remotely.
    - - File deleted remotely.
  - Outgoing modification to repository:
    - - File content or properties modified locally.
    - - New file added locally.
    - - File deleted locally.
  - **Pseudo-conflict state** - A resource being locally and remotely modified at the same time, or a parent directory of such a resource.
  - **Real conflict state** - A resource that had both incoming and outgoing changes and not all the differences could be merged automatically through the update operation (manually editing the local file is necessary for resolving the conflict).

Figure 743. Working Copy View - Modified View Mode



- **Incoming** - The resource tree presents only incoming changes.
- **Outgoing** - The resource tree presents only outgoing changes.
- **Conflicts** - The resource tree presents only conflicting changes (real conflicts and pseudo-conflicts).

The following columns provide information about the resources:

- **Name** - Resource name. Resource icons can have the following decorator icons:
  - Additional status information:
    - **Propagated modification marker** - A folder marked with this icon indicates that the folder itself presents some changes (such as modified properties) or a child resource has been modified.
    - **External** - This indicates a mapping of a local directory to the URL of a versioned resource. It is declared with a `svn:externals` property in the parent folder and it indicates a working copy not directly related with the parent working copy that defines it.
    - **Switched** - This indicates a resource that has been switched from the initial repository location to a new location within the same repository. The resource goes to this state as a result of the Switch action *(on page 2964)* executed from the contextual menu of the Working Copy view.
    - **Grayed** - A resource with a grayed-out icon, but no overlaid icon, is an ignored resource. It is obtained with the **Add to svn:ignore** action.
  - Current SVN depth of a folder:
    - **Immediate children (immediates)** (a variant of sparse checkout *(on page 2984)*) - The directory contains only direct file and folder children. Child folders ignore their content.
    - **File children only (files)** (a variant of sparse checkout *(on page 2984)*) - The directory contains only direct file children, disregarding any child folders.
    - **This folder only (empty)** (a variant of sparse checkout *(on page 2984)*) - The directory discards any child resource.

  Note:
  - Any folder not marked with one of the depth icons, has recursive depth (*infinity*) set by default (presents all levels of child resources).
  - Although folders not under version control can have no depth set, Oxygen XML Editor presents *unversioned* and *ignored* folders with *empty* depth when **Show unversioned directories content** or **Show ignored directories content** options are not selected.

- **Local file status** - Shows the changes of working copy resources that were not committed to the repository yet. The following icons are used to mark resource status:
  - - Resource is *not under version control* (*unversioned*).
  - - Resource is being *ignored* because it is not under version control and its name matches a file name pattern defined in one of the following places:

        - *global-ignores* section in the SVN client-side *config* file *(on page 2908)*.

          Attention:
          If you do not explicitly set the `global-ignores` runtime configuration option (either to your preferred set of patterns or to an empty string), Subversion uses the default value.

        - **Application global ignores** option *(on page 293)* of Oxygen XML Editor.
        - The value of a *svn:ignore* property *(on page 2922)* set on the parent folder of the resource being ignored.
    - - Marks a newly created resource, *scheduled for addition* to the version control system.
    - - Marks a resource *scheduled for addition*, created by copying a resource already under version control and inheriting all its SVN history.
    - - The content of the resource has been *modified*.
    - - Resource has been *replaced* in your working copy (the file was scheduled for deletion, and then a new file with the same name was scheduled for addition in its place).
    - - Resource is *deleted* (scheduled for deletion from **Repository** upon the next commit).
    - - The resource is *incomplete* (as a result of an interrupted *check out* or *update* operation).
    - - The resource is *missing* because it was moved or deleted without using an SVN-aware application.
    - - The contents of the resource is in real *conflict* state *(on page 2930)*.
    - - Resource is in a *name conflict* state.
    - - Resource is in *tree conflict* state after an update operation because:
        - Resource was locally modified and incoming deleted from repository.
        - Resource was locally scheduled for deletion and incoming modified.
    - - Resource is *obstructed* (versioned as one kind of object: file, directory, or symbolic link, but has been replaced outside Syncro SVN Client by a different kind of object).
- **Local properties status** - Marks the resources that have SVN properties, with the following possible states:
    - - The resource has SVN properties set.
    - - The resource properties have been modified.
    - - Properties for this resource are in real conflict *(on page 2930)* with property updates received from the repository.
- **Revision** - The current revision number of the resource.
- **Date** - Date when the resource was last time modified on the disk.
- **BASE Revision** - The revision number of the pristine version of the resource.
- **BASE Date** - Date when the pristine version of the resource was last time committed in the repository.
- **Author** - Name of the person who made the last modification on the pristine version of the resource.
- **Remote file status** - Shows changes of resources recently modified in the repository. The following icons are used to mark incoming resource status:
    - - Resource is newly added in repository.
    - - The content of the resource has been modified in repository.

- - Resource was replaced in repository.
- - Resource was deleted from repository.

- **Remote properties status** - Resources marked with the icon have incoming modified properties from the repository.
- **Remote revision** - Revision number of the resource latest committed modification.
- **Remote date** - Date of the resource latest modification committed on the repository.
- **Remote author** - Name of the author who committed the latest modification on the repository.

- **Lock information** - Shows the lock state of a resource. The lock mechanism is a convention intended to help you signal other users that you are working with a particular set of files. It minimizes the time and effort wasted in solving possible conflicts generated by clashing commits. A lock gives you exclusive rights over a file, only if other users follow this convention and they do not try to bypass the lock state of a file.

  A folder can be locked only by the SVN client application, completely transparent to the user, if an operation in progress was interrupted unexpectedly. As a result, folders affected by the operation are marked with the symbol. To clear the locked state of a folder, use the **Clean up** action.

  > **Note:**
  > Users can lock only files.

  The following lock states are displayed:
  - *no lock* - the file is not locked. This is the default state of a file in the SVN repository.
  - *remotely locked* ( ) - shown when:
    - Another user has locked the file in the repository.
    - The file was locked by the same user from another working copy.
    - The file was locked from the **Repositories** view.

    If you try to commit a new revision of the file to the repository, the server does not allow you to bypass the file lock.

    > **Note:**
    > To commit a new revision, you need to wait for the file to be unlocked. Ultimately, you might try to *break* or *steal* the lock, but this is not what other users expect. Use these actions carefully, especially when you are not the file lock owner.

  - *locked* ( ) - displayed after you have locked a file from the current working copy. Now you have exclusive rights over the corresponding file, being the only one who can commit changes to the file in the repository.

> **Note:**
> Working copies keep track of their locked files, so the locks are presented between different sessions of the application. Synchronize your working copy with the repository to make sure that the locks are still valid (not *stolen* or *broken*).

- *stolen* ( ) - a file already locked from your working copy is being locked by another user. Now the owner of the file lock is the user who stole the lock from you.
- *broken* ( ) - a file already locked from your working copy is no longer locked in the repository (it was unlocked by another user).

> **Note:**
> To remove the *stolen* or *broken* states from your working copy files, you have to **Update** them.

If one of your working copy files is locked, hover the mouse pointer over the lock icon to see more information:

- Lock type - current file lock state
- Owner - the name of the user who created the lock
- Date - the date when the user locked the file
- Expires on - date when the lock expires. Lock expiry policy is set in the repository options, on the server side
- Comment - the message attached when the file was locked

- **Size** - Resource size on disk
- **Type** - Contains the resource type or file extension

> **Note:**
> The working copy table allows you to show or hide any of its columns and also to sort its contents by any of the displayed columns. The table header provides a contextual menu that allows you to customize the displayed information.

The toolbar contains the following options for switching to a different working copy:

- **List of Defined Working Copies** - A drop-down menu that contains all the working copies Oxygen XML Editor is aware of. When you select a different working copy from the list, the newly selected working copy content is scanned and displayed in the **Working Copy** view.
- **Working Copies Manager (on macOS)** - Opens a dialog box that displays the working copies Oxygen XML Editor is aware of. In this dialog box, you can add existing working copies or remove those

you no longer need. If you try to add a folder that is not a valid Subversion working copy, Oxygen XML Editor warns you that the selected directory is not under version control.

> **Note:**
> Removing a working copy from this dialog box does NOT remove it from your file system; you will have to do that manually.

Working Copy Settings

The **Settings** button from the toolbar of the **Working Copy** view provides the following options:

- **Show unversioned directories content** - Displays the content of unversioned directories.

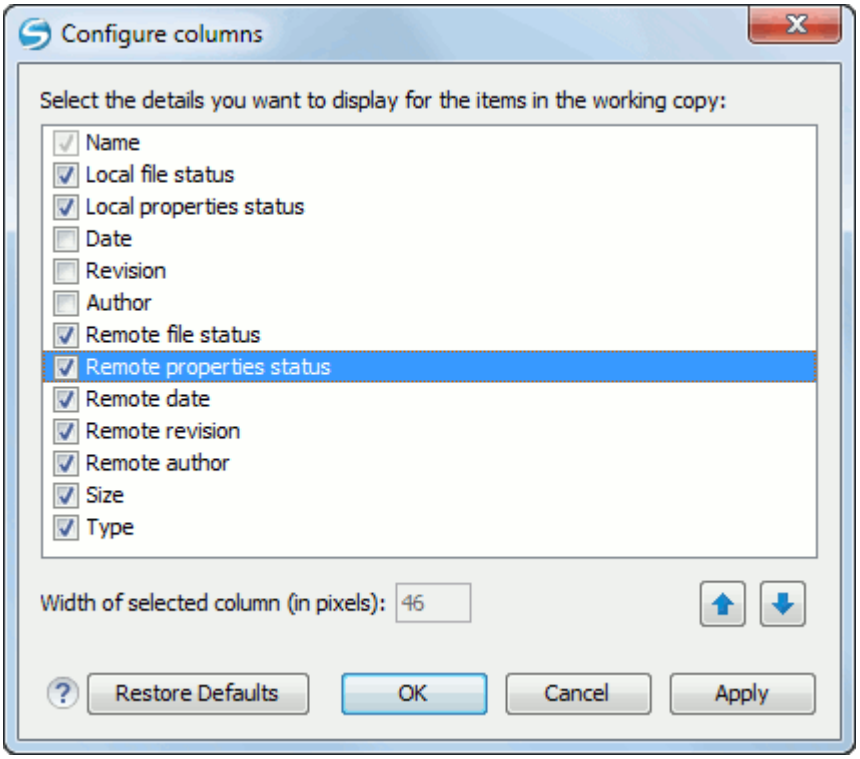
  > **Note:**
  > If this option is not selected, it will be ignored for items that, after a synchronize, are reported as incoming from the repository. This applies for all working copy modes, except **All Files**.

- **Show ignored items** - Displays the ignored resource when **All Files** mode is selected.
- **Show ignored directories content** - Displays the content of ignored directories when **All Files** mode is selected.

  > **Note:**
  > Although *ignored* items are not presented in the **Modified**, **Incoming**, and **Conflicts** modes, they will be if, after a synchronize, they are reported as incoming from the repository.

- **Show deleted items** - Displays the deleted resource when **All Files** mode is selected. All other modes always display deleted resources, disregarding this option.
- **Tree** / **Compressed** / **Flat** - Affect the way information is displayed inside the **Modified**, **Incoming**, **Outgoing**, and **Conflicts** view modes.
- **Configure columns** - Allows you to customize the structure of the **Working Copy** view data. This action opens the following dialog box:

Figure 744. Configure Columns of Working Copy View



The order of the columns can be changed with the two arrow buttons. The column size can be edited in the **Width of selected column** field. The **Restore Defaults** button reverts all columns to the default order, width, and enabled/disabled state from the installation of the application.

Working Copy Format

When an SVN working copy is loaded, Syncro SVN Client first checks the format of the working copy:

- If the format is older than SVN 1.7, you are prompted to upgrade it to SVN 1.8 to load it.
- If the format is 1.7, Syncro SVN Client takes into account the state of the **When loading an old format working copy**option *(on page 292)*.

To change how working copy formats are handled, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **SVN > Working copy**, and configure the options in the **Administrative area** *(on page 292)* section.

Note:

- The format of the working copy can be downgraded or upgraded at any time with the **Upgrade** and **Downgrade** actions available in the **Tools** menu. These actions allow switching between SVN 1.7 and SVN 1.8 working copy formats.
- SVN 1.7 working copies cannot be downgraded to older formats.

Refresh a Working Copy

A refresh is a frequent operation triggered automatically when you switch between two working copies using the toolbar selector of the **Working Copy** view and when you switch between Oxygen XML Editor and other applications.

The **Working Copy** view features a fast refresh mechanism: the content is cached locally when loading the working copy for the first time. Later on, when the same working copy is displayed again, the application uses this cache to detect the changes between the cached content and the current content found on disk. The refresh operation is run on these changes only, thus improving the response time. improvement is noticeable especially when working with large working copies.

Working Copy View Contextual Menu Actions

The contextual menu in the **Working Copy** view contains the following actions:

Edit conflict (Ctrl + E (Command + E on macOS))

Opens the **Compare** editor, allowing you to modify the content of the currently conflicting resources. For more information about editing conflicts, see Edit conflicts *(on page 2932)*.

Open in Compare Editor (Ctrl + Alt + C (Command + Option + C on macOS))

Displays changes made in the currently selected file.

Open (Ctrl + O (Command + O on macOS))

Opens the selected resource from the working copy. Files are opened with an internal editor or an external application associated with that file type, while folders are opened with the default file system browsing application (Windows Explorer on Windows, Finder on macOS, etc).

Open with...

Submenu that allows you to open the selected resource either with Oxygen XML Editor or with another application.

Show in Explorer/Show in Finder

Opens the parent directory of the selected working copy file and selects the file.

 **Expand All (Ctrl + Alt + X (Command + Option + X on macOS))**

Displays all descendants of the selected folder. The same behavior is obtained by double-clicking a collapsed folder.

 **Refresh(F5)**

Re-scans the selected resources recursively and refreshes their status in the working copy view.

 **Synchronize (Ctrl + Shift + S (Command + Shift + S on macOS))**

Connects to the repository and determines the working copy and repository changes made to the selected resources. The application switches to **Modified** view mode if the **Always switch to 'Modified' mode** option *(on page 292)* is selected.

Update (Ctrl + U (Command + U on macOS))

Updates the selected resources to the *HEAD* revision (latest modifications) from the repository. If the selection contains a directory, it will be updated depending on its depth.

Update to revision/depth

Allows you to update the selected resources from the working copy to an earlier revision from the repository. You can also select the update *depth* for the current folder. You can find out more about the *depth* term in the sparse checkouts *(on page 2984)* section.

Commit

Collects the outgoing changes from the selected resources in the working copy and allows you to choose exactly what resources to commit. A directory will always be committed recursively. Unversioned resources will be deselected by default. In the **Commit** dialog box you can also enter a comment before sending your changes to the repository.

Revert (Ctrl + Shift + V (Command + Shift + V on macOS))

Undoes all local changes for the selected resources. It does not contact the repository and the files are obtained from the Apache Subversion™ pristine copy. It is available only for modified resources. See Revert your changes *(on page 2934)* for more information.

Override and Update

Drops any outgoing change and replaces the local resource with the HEAD revision. This action is available on resources with outgoing changes, including conflicting ones. See the Revert your changes *(on page 2934)* section.

Override and Commit

Drops any incoming changes and sends your local version of the resource to the repository. This action is available on conflicting resources. For more information see Drop incoming modifications *(on page 2936)*.

Mark Resolved (Ctrl + Shift + R (Command + Shift + R on macOS))

Instructs the Subversion system that you resolved a conflicting resource. For more information, see Merge conflicts *(on page 2935)*.

Mark as Merged (Ctrl + Shift + M (Command + Shift + M on macOS))

Instructs the Subversion system that you resolved the pseudo-conflict by merging the changes and you want to commit the resource. Read the Merge conflicts *(on page 2935)* section for more information about how you can solve the pseudo-conflicts.

Create patch (Ctrl + Alt + P (Command + Option + P on macOS))

Allows you to create a file containing all the differences between two resources, based on the `svn diff` command. To read more about creating patches, see the section about patches *(on page 2969)*.

Compare with:

- **Latest from HEAD (Ctrl + Alt + H (Command + Option + H on macOS))** - Performs a 3-way diff operation between the selected file and the *HEAD* revision from the repository and displays the result in the **Compare view**. The common ancestor of the 3-way diff operation is the *BASE* version of the file from the local working copy.
- **BASE revision (Ctrl + Alt + C (Command + Option + C on macOS))** - Compares the working copy file with the BASE revision file (the so-called *pristine copy*).
- **Revision (Ctrl + Alt + R (Command + Option + R on macOS))** - Displays the **History view** that contains the log history of that resource.
- **Branch/Tag** - Opens the **Compare with Branch/Tag** dialog box that allows you to specify another file from the repository *(on page 3025)* (**To URL** field) to compare with the working copy file. You can specify the revision of the repository file by choosing between **HEAD revision** or specific **Other revision**.

  Tip:
  To compare with a file that was deleted, moved, or replaced, you need to specify the original URL (before the file was removed) and use a *peg* revision *(on page 3027)* at the end (for example, `URL@rev1234`).

- **Each other** - Compares two selected files with each other.

These *compare* actions are available only if the selected resource is a file.

Replace with:

- **Latest from HEAD** - Replaces the selected resources with their versions from the *HEAD* revision of the repository.
- **BASE revision** - Replace the selected resources with their versions from the pristine copy (the BASE revision).

Note:
In some cases it is impossible to replace the currently selected resources with their versions from the *BASE/HEAD* revision:

- For the **Replace with BASE revision** action, the resources being unversioned or added have no *BASE* revision, and thus cannot be replaced. However, they will be deleted if the action is invoked on a parent folder. The action will never work for missing folders or for obstructing files (folders being obstructed by a file), since you cannot recover a tree of folders.
- For the **Replace with latest from HEAD** action, you must be aware that there are cases when resources will be completely deleted or reverted to the BASE revision and then updated to a HEAD revision to avoid conflicts. These cases are:

- The resource is *unversioned*, *added*, *obstructed*, or *modified*.
- The resource is affected by a `svn:ignore` or `svn:externals` property that is locally added on the parent folder and not yet committed to the repository.

Show History (Ctrl + H (Command + H on macOS))

Displays the **History view** where the log history for the selected resource will be presented. For more details about resource history, see the sections about the resource history view *(on page 3005)* and requesting the history for a resource *(on page 2944)*.

Show Annotation (Ctrl + Shift + A (Command + Shift + A on macOS))

Opens the **Show Annotation** dialog box that computes the annotations for a file and displays them in the **Annotations** view *(on page 3012)*, along with the history of the file in the **History** view.

Revision Graph (Ctrl + G (Command + G on macOS))

This action allows you to see the graphical representation history of a resource. For more details about the revision graph of resources, see Revision Graph *(on page 3020)*.

Copy URL Location (Ctrl + Alt + U (Command + Option + U on macOS))

Copies the encoded URL of the selected resource from the Working Copy to the clipboard.

Mark as copied

You can use this action to mark an item from the working copy as a copy of another item under *version control*, when the copy operation was performed outside of an SVN client. The **Mark as copied** action is available when you select two items (both the new item and source item), and it depends on the state of the source item.

Mark as moved

You can use this action to mark an item from the working copy as being moved from another location of the working copy, when the move operation was performed outside of an SVN client. The **Mark as moved** action is available when you select two items from different locations (both the new item and the source item that is usually reported as *missing*), and it depends on the state of the source item.

Mark as renamed

You can use this action to mark an item from the working copy as being renamed outside of an SVN client. The **Mark as renamed** action is available when you select two items from the same directory (both the new item and the source item that is usually reported as *missing*), and it depends on the state of the source item.

Copy to

Copies the currently selected resource to a specified location.

Move to (Ctrl + M (Command + M on macOS))

Moves the currently selected resource to a specified location.

Rename (F2)

As with the move command, a copy of the original resource will be made with the new name and the original will be marked as deleted. Note that you can only rename one resource at a time.

Delete (Delete)

Schedules selected items for deletion upon the next commit and removes them from the disk. Depending on the state of each item, you are prompted to confirm the operation.

New:

- **New File** - Creates a new file inside the selected folder. The newly created file will be added under version control only if the parent folder is already versioned.
- **New Folder (Ctrl + Shift + F (Command + Shift + F on macOS))** - Creates a child folder inside the selected folder. The newly created folder will be added under version control only if its parent is already versioned.
- **New External Folder (Ctrl + Shift + W (Command + Shift + W on macOS))** - This operation allows you to add a new external definition on the selected folder. An external definition is a mapping of a local directory to a URL of a versioned directory *(on page 3025)*, and ideally a particular revision, stored in the `svn:externals` property of the selected folder.

  Tip:
  You can specify a particular revision of the external item by using a *peg* revision *(on page 3027)* at the end of the URL (for example, `URL@rev1234`). You can also use peg revisions to access external items that were deleted, moved, or replaced.

  The URL used in the external definition format can be relative. You can specify the repository URL that the external folder points to by using one of the following relative formats:
  - **../** - Relative to the URL of the directory that the `svn:externals` property is set.
  - **^/** - Relative to the root of the repository where the `svn:externals` property is versioned.
  - **//** - Relative to the scheme of the URL of the directory that the `svn:externals` property is set.
  - **/** - Relative to the root URL of the server that has the `svn:externals` property versioned.

  Important:
  To change the target URL of an external definition, or to delete an external item, do the following:

1. Modify or delete the item definition found in the `svn:externals` property that is set on the parent folder.
2. For the change to take effect, use the **Update** operation on the parent folder of the external item.

Note:
Syncro SVN Client does not support definitions of local relative external items.

Add to "svn:ignore" (Ctrl + Alt + I (Command + Option + I on macOS))

Allows you to add files that should not participate in the *version control* operations inside your working copy. This action can only be performed on resources not under *version control*. It actually modifies the value of the `svn:ignore` property in the parent directory of the resource. Read more about this in the Ignore Resources Not Under Version Control *(on page 2922)* section.

Add to version control (Ctrl + Alt + V (Command + Option + V on macOS))

Allows you to add resources that are not under *version control*. For further details, see Add Resources to Version Control *(on page 2920)* section.

Remove from version control

Schedules the selected items for deletion from the repository upon the next commit. The items are not removed from the file system after committing.

Clean up (Ctrl + Shift + C (Comman + Shift + Cd on macOS))

Performs a maintenance cleanup operation on the selected resources from the working copy. This operation removes the Subversion maintenance locks that were left behind. This is useful when you already know where the problem originated and want to fix it as quickly as possible. It is only active for resources under *version control*.

Locking:

- **Scan for locks (Ctrl + L (Command + L on macOS))** - Contacts the repository and recursively obtains the list of locks for the selected resources. A dialog box containing the locked files and the lock description will be displayed. This is only active for resources under *version control*. For more details see Scanning for locks *(on page 2926)*.
- **Lock (Ctrl + K (Command + K on macOS))** - Allows you to lock certain files that need exclusive access. You can write a comment describing the reason for the lock and you can also force (*steal*) the lock. This action is active only on files under *version control*. For more details on the use of this action see Locking a file *(on page 2927)*.
- **Unlock (Ctrl + Alt + K (Command + Option + K on macOS))** - Releases the exclusive access to a file from the repository. You can also choose to unlock it by force (*break the lock*).

Show SVN Properties (Ctrl + P (Command + P on macOS))

Brings up the Properties view *(on page 3018)* and displays the SVN properties for the selected resource.

Show SVN Information (Ctrl + I (Command + I on macOS))

Provides additional information for the selected resource from the working copy. For more details, go to Obtain information for a resource *(on page 2943)*.

Drag and Drop Operations

The structure of the files tree can be changed with drag and drop operations inside the **Working Copy** view. These operations behave in the same way with the **Copy to**/**Move to** operations.

Also, files and folders can be added to the file tree of the view as *unversioned* resources by drag and drop operations from other applications (for example, from Windows Explorer or macOS Finder). In this case, the items from the file system are only copied, without removing them from their original location.

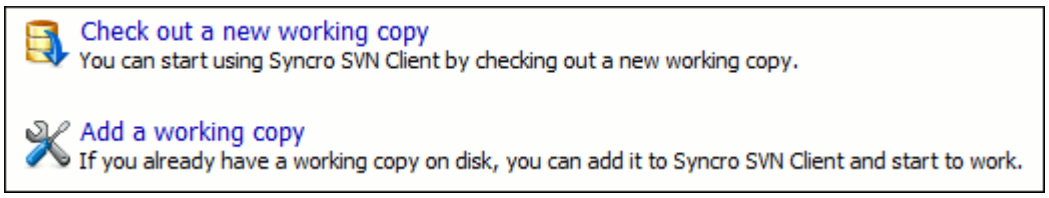
Attention:
When you drag items from the working copy to a different application, the performed operation is controlled by that application. This means that the moved items are left as *missing* in the working copy (items are moved in the file system only, but no SVN versioning meta-data is changed).

Assistant Actions

To ensure a continuous and productive work flow, when a view mode has no files to present, it offers a set of guiding actions with some possible paths to follow.

Initially, when there is no working copy configured the **All Files** view mode lists the following two actions:

Figure 745. All Files Panel



For **Modified**, **Incoming**, **Outgoing**, **Conflicts** view modes, the following actions may be available, depending on the current working copy state in various contexts:

- **Synchronize with Repository** - Available only when there is nothing to present in the **Modified** and **Incoming** view modes.
- **Switch to Incoming** - Selects the **Incoming** view mode.
- **Switch to Outgoing** - Selects the **Outgoing** view mode.

- **Switch to Conflicts** - Selects the **Conflicts** view mode.
- **Show all changes/incoming/outgoing/conflicts** - Depending on the currently selected view mode, this action presents the corresponding resources after a synchronize operation was executed only on a part of the working copy resources.
- **(Information message)** - Informs you why there are no resources presented in the currently selected view mode.

History View

In Apache Subversion™, both files and directories are versioned and have a history. If you want to examine the history for a selected resource and find out what happened at a certain revision you can use the **History view** that can be accessed from Repositories view *(on page 2985)*, Working Copy view *(on page 2990)*, Revision Graph *(on page 3020)*, or Directory Change Set view *(on page 3010)*. From the **Working copy view** you can display the history of local versioned resources. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

The view consists of four distinct areas:

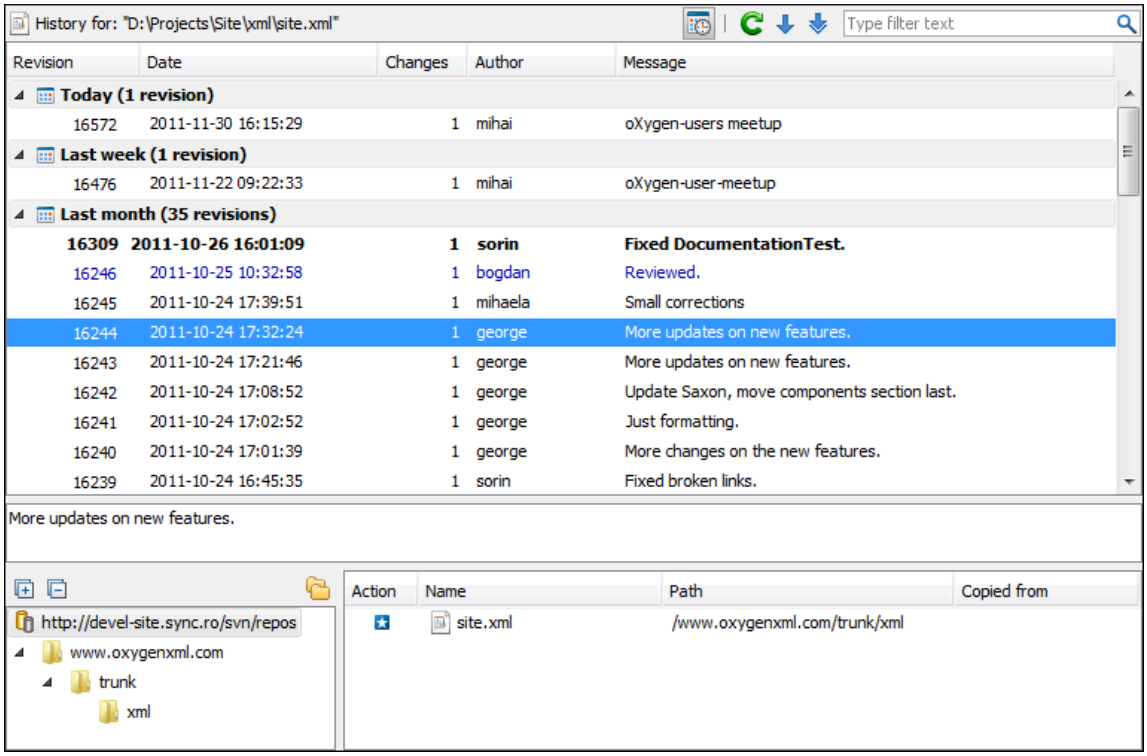
- The table showing details about each revision, such as revision number, commit date and time, number of changes (more details available in the tooltip), author's name, and a fragment of the commit message.

  Some revisions may be highlighted to emphasize:
  - The current revision of the resource that has the history displayed - a bold font revision.
  - The last revision where the content or properties of the resource were modified - blue font revision.

  > **Note:**
  > Both font highlights may be applied for the same revision.

- The complete commit message for the selected revision.
- A tree structure showing the folders where the modified resources are located. You can compress this structure to a more compact form that focuses on the folders that contain the actual modifications.
- The list of resources modified in the selected revision. For each resource, the type of action done against it is marked with one of the following symbols:
  - - A newly created resource.
  - - A newly created resource, copied from another repository location.
  - - The content/properties of the resource were *modified*.
  - - Resource was *replaced* in the repository.
  - - Resource was deleted from the repository.

Figure 746. History View

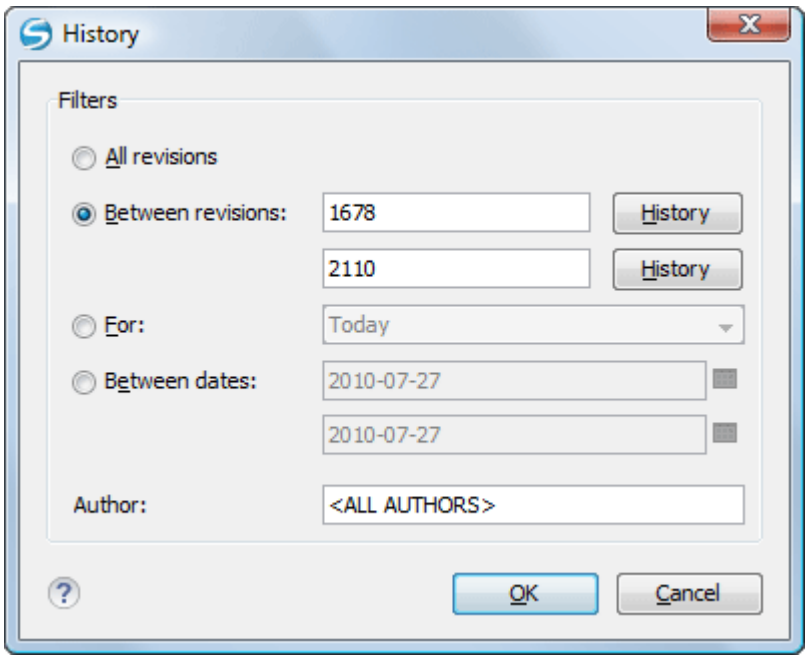


You can group revisions in predefined time frames (today, yesterday, this week, this month), by pressing the **Group by date** button from the toolbar.

History Filter Dialog Box

The **History view** does not always show all the changes ever made to a resource because there may be thousands of changes and retrieving the entire list can take a long time. Normally you are interested in the more recent ones. That is why you can specify the criteria for the revisions displayed in the **History view** by selecting one of several options presented in the **History** dialog box that is displayed when you invoke the **Show History** action.

Figure 747. History Filters Dialog Box



Options for the set of revisions presented in the History view are:

- All revisions of the selected resource.
- Only revisions between a start revision number and an end revision number.
- Only revisions added in a period of time (such as today, last week, last month, etc.)
- Only revisions between a start and an end date.
- Only revisions committed by a specified SVN user.

The toolbar of the **History view** has two buttons for extending the set of revisions presented in the view: **Get next 50** and **Get all**.

History Filter Field

When only the history entries that contain a specified substring need to be displayed in the **History** view, the filter field displayed at the top of this view is a useful tool. Just enter the search string in the field next to the **Find** label. Only the items (with an author name, commit message, revision number, or date) that match the search string are kept in the **History** view. When you click the **Search** button, the filter action is executed and the content of the table is updated.

History View Contextual Menu Actions

The **History** view contains the following contextual menu actions:

Compare with working copy

Compares the selected revision with your working copy file. It is available only when you select a file.

Open

Opens the selected revision of the file into the Editor. This is available only for files.

Open with

Displays the **Open with** dialog box to specify the editor where the selected file will be opened.

Get Contents

Replaces the current version from the working copy with the contents of the selected revision from the history of the file. The *BASE* version of the file is not changed in the working copy so that after this action the file will appear as modified in a synchronization operation, that is newer than the *BASE* version, even if the contents is from an older version from history.

Save as

Allows you to save the contents of a file as it was committed at a certain revision. This option is available only when you access the history of a file.

Copy to

Copies to the repository the item whose history is displayed, using the selected revision. This option is active only when presenting the history for a repository item (URL).

Note:
This action can be used to resurrect deleted items also.

Revert changes from this revision

Reverts changes that were made in the selected revisions. The are reverted only in the working copy and do not affect the repository items. It does not replace your working copy items with those from the selected revisions. This action is available when the resource history was launched for a local working copy resource.

Note:
For items displayed in the **Affected Paths** section that were *added*, *deleted*, or *replaced*, this action has no effect because such changes are considered to be changes to the parent directory. To revert these types of changes, follow these steps:

1. Request the history for the parent directory.
2. Identify the revision that contains the changes you want to revert.
3. Invoke the action on that revision.

Warning:
There are instances where the SVN Client is not able to identify the corresponding working copy item for the selected item in the **Affected Paths** section. In this case, the action does not proceed and an error message is displayed. For example, the selected

item in the **Affected Paths** section is from a different repository location than the working copy item that has the history displayed.

Update to revision

Updates your working copy resource to the selected revision. This is useful if you want your working copy to reflect a time in the past. It is best to update a whole directory in your working copy, not just one file. Otherwise, your working copy is inconsistent and you are unable to commit your changes.

Check out

Checks out a new working copy of the directory that has the history presented, from the selected revision.

Export

Opens the **Export** dialog box *(on page 2980)* that allows you to configure options for exporting a folder from the repository to the local file system.

Show Annotation (Ctrl + Shift + A (Command + Shift + A on macOS))

Opens the **Show Annotation** dialog box that computes the annotations for a file and displays them in the **Annotations** view *(on page 3012)*, along with the history of the file in the **History** view.

Change

Allows you to change commit data for a file:

- *Author* - Changes the name of the SVN user that committed the selected revision.
- *Message* - Changes the commit message of the selected revision.

When two resources are selected in the **History** view, the contextual menu contains the following actions:

Compare revisions

When the resource is a file, the action compares the two selected revisions using the **Compare** view. When the resource is a folder, the action displays the set of all resources from that folder that were changed between the two revision numbers.

Revert changes from these revisions

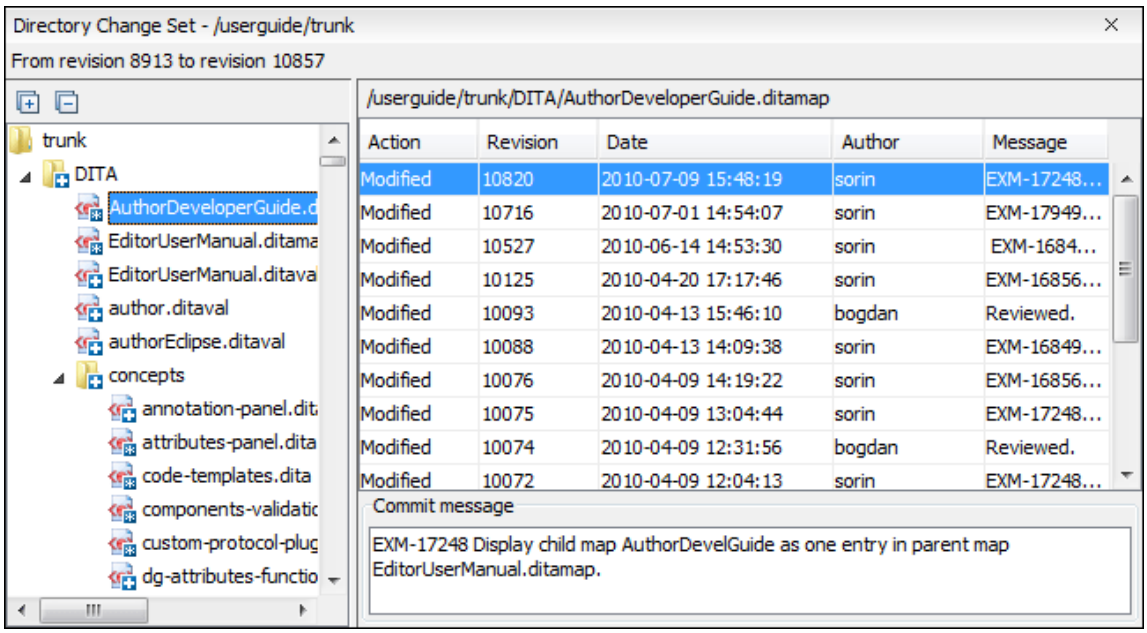
Similar to the `svn merge` command, it merges two selected revisions into the working copy resource. This action is only available when the resource history was requested for a working copy item.

For more information about the **History view** and its features, see the Request history for a resource *(on page 2944)* and Using the resource history view *(on page 3005)* sections.

Directory Change Set View

The result of comparing two reference revisions from the history of a folder resource is a set with all the resources changed between the two revision numbers. The changed resources can be contained in the folder or in a subfolder of that folder. These resources are presented in a tree format. For each changed resource all the revisions committed between the two reference revision numbers are presented.

Figure 748. Directory Change Set View



The set of changed resources displayed in the tree is obtained by running the action **Compare revisions** available on the contextual menu of the **History** view when two revisions of a folder resource are selected in the **History** view.

The left side panel of the view contains the tree hierarchy with the names of all the changed resources between the two reference revision numbers. The right side panel presents the list with all the revisions of the resource selected in the left side tree. These revisions were committed between the two reference revision numbers. Selecting one revision in the list displays the commit message of that revision in the bottom area of the right side panel.

Double-clicking a file listed in the left-side tree performs a diff operation between the two revisions of the file corresponding to the two reference revisions. Double-clicking one of the revisions displayed in the right-side list of the view performs a diff operation between that revision and the previous one for the same file.

The contextual menu of the right side list contains the following actions:

Compare with previous version

Performs a diff operation between the selected revision in the list and the previous one.

Open

Opens the selected revision in the associated editor type.

Open with

Displays a dialog box with the available editor types and allows you to select the editor type for opening the selected revision.

Save as

Saves the selected file as it was in the selected revision.

Copy to

Copies to the repository the item whose history is displayed, using the selected revision.

> **Note:**
> This action can be used to resurrect deleted items also.

Check out

Checks out a new working copy of the selected directory, from the selected revision.

Export

Opens the **Export** dialog box *(on page 2980)* that allows you to configure options for exporting a folder from the repository to the local file system.

Show Annotation (Ctrl + Shift + A (Command + Shift + A on macOS))

Opens the **Show Annotation** dialog box that computes the annotations for a file and displays them in the **Annotations** view *(on page 3012)*, along with the history of the file in the **History** view.

Show SVN Information (Ctrl + I (Command + I on macOS))

Provides additional information for a selected resource. For more details, go to Obtain information for a resource *(on page 2943)*.

Editor Panel of SVN Client

You can open a file for editing in an internal built-in editor. There are default associations between frequently used file types and the internal editors in the File Types preferences panel *(on page 306)*.

The internal editor can be accessed either from the Working copy view *(on page 2990)* or from the History view *(on page 3005)*. No actions that modify the content are allowed when the editor is opened with a revision from history.

Only one file at a time can be edited in an internal editor. If you try to open another file it will be opened in the same editor window. The editor provides syntax highlighting for known file types. This means that a different color will be used for each recognized token type found in the file. If the file's content type is unknown you will be prompted to choose the proper way the file should be opened.

After editing the content of the file in an internal editor you can save it to disk by using the **Save** action from the File *(on page 2896)* menu or the **Ctrl + S (Command + S on macOS)** key shortcut. After saving your file you can see the file changed status in the **Working Copy** view *(on page 2990)*.

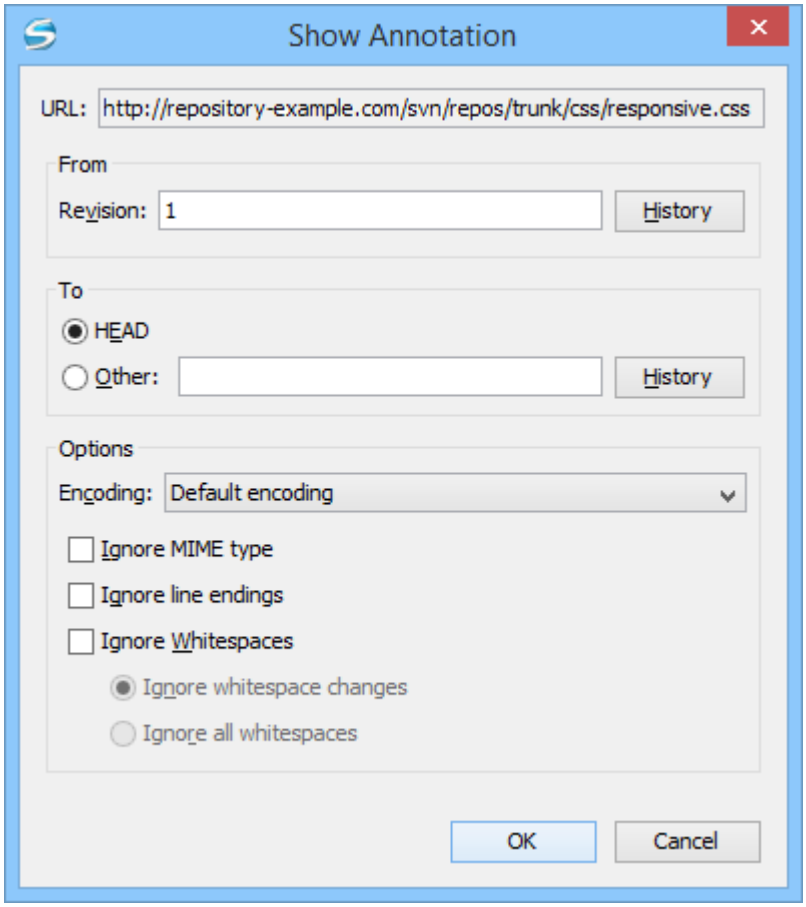
If the internal editor associated with a file type is not the XML Editor, then the encoding set in the preferences for *Encoding for non XML files (on page 175)* is used for opening and saving a file of that type. This is necessary because in the case of XML files, the encoding is usually declared at the beginning of the XML file in a special declaration or it assumes the default value UTF-8, but in the case of non-XML files, there is no standard mechanism for declaring the encoding for the file.

Annotations View

Sometimes you need to know not only what was changed in a file, but also who made those changes. The **Annotations** view displays the revision and the author that changed every line in a file. The annotations of a file are computed and this view is opened with the **Show Annotation** action, which is available in the **History** menu, and from the contextual menu of the following views: **Repositories** view *(on page 2985)*, **Working copy** view *(on page 2990)*, **History** view *(on page 3005)*, and **Directory Change Set** view *(on page 3010)*.

This action opens a dialog box that allows you to configure some options for showing the annotations.

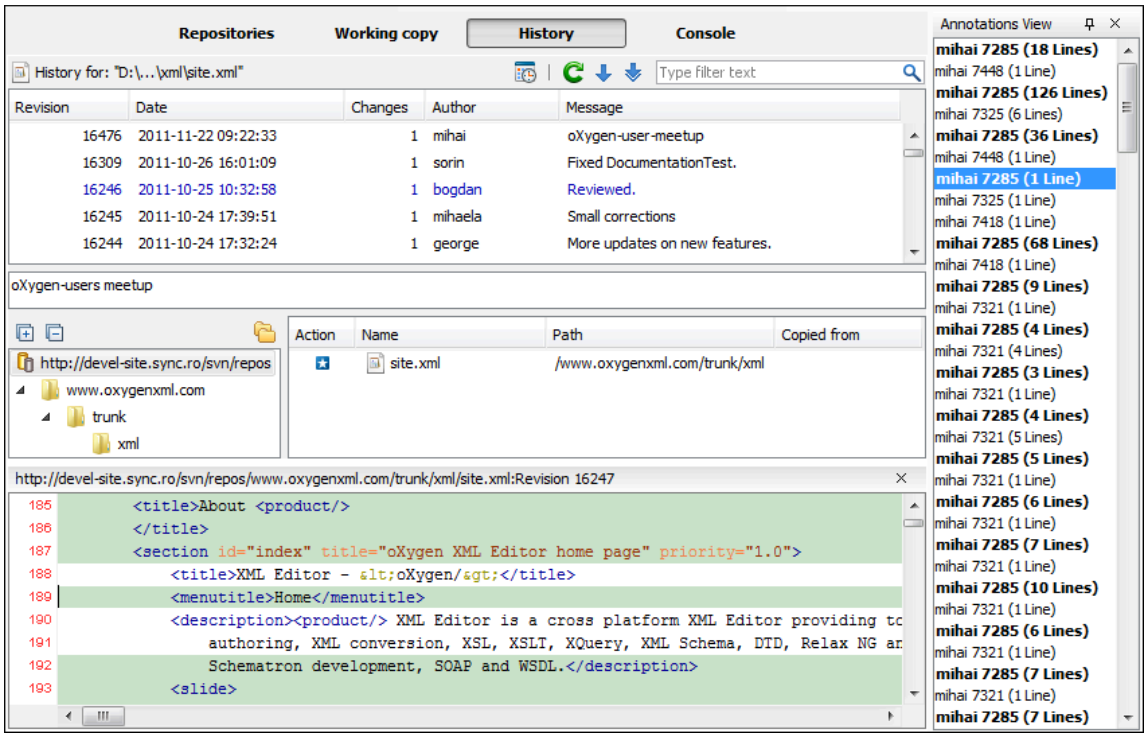
Figure 749. Show Annotation Options Dialog Box



Once you have configured the options and click **OK**, the **Annotations** view is displayed (by default, on the right side of the application). You can click a line in the editor panel where the file is opened to see the revision where the line was last modified. The same revision is highlighted in the **History view** and you can also see all the lines that were changed in the same revision highlighted in the editor panel. Also, the entries of the **Annotations view** corresponding to that revision are highlighted. Therefore, the **Annotations view**,

History view, and annotations editor panel are all synchronized. Clicking a line in one of them highlights the corresponding lines in the other two.

Figure 750. Annotations View



The following options can be configured in the **Show Annotation** dialog box:

From Revision Section

Select the revision to have the annotation computed. If you click the **History** button, the **History** dialog box *(on page 2918)* is displayed, which allows you to select a revision.

To Revision Section

Select the ending revision by choosing between the **HEAD** revision or specify it in the **Other** text box. If you click the **History** button, the **History** dialog box *(on page 2918)* is displayed, which allows you to select a revision.

Encoding

Select the encoding to be used when the annotation is computed. For each line of text, the SVN Client looks through the history of the file to be annotated see when it was last modified, and by whom. It is required that it is in the form of a text file. Therefore, encoding is needed to properly decode and read the file content. By default, the encoding of the operating system is used.

Ignore MIME type

If selected, the file is treated as a text file and ignores what the SVN system infers from the `svn:mime-type` property.

Ignore line endings

If selected, the differences in line endings are ignored when the annotation is computed.

Ignore whitespaces

If selected, it allows you to specify how the whitespace changes should be handled. When selected, you can then choose between two options:

- **Ignore whitespace changes** - Ignores changes in the amount of whitespaces or to their type (for example, when changing the indentation or changing tabs to spaces).

  Note:
  Whitespaces that were added where there were none before, or that were removed, are still considered to be changes.

- **Ignore all whitespaces** - Ignores all types of whitespace changes.

Tip:
Selecting any of these *ignore* options can help you better determine the last time a meaningful change was made to a given line of text.

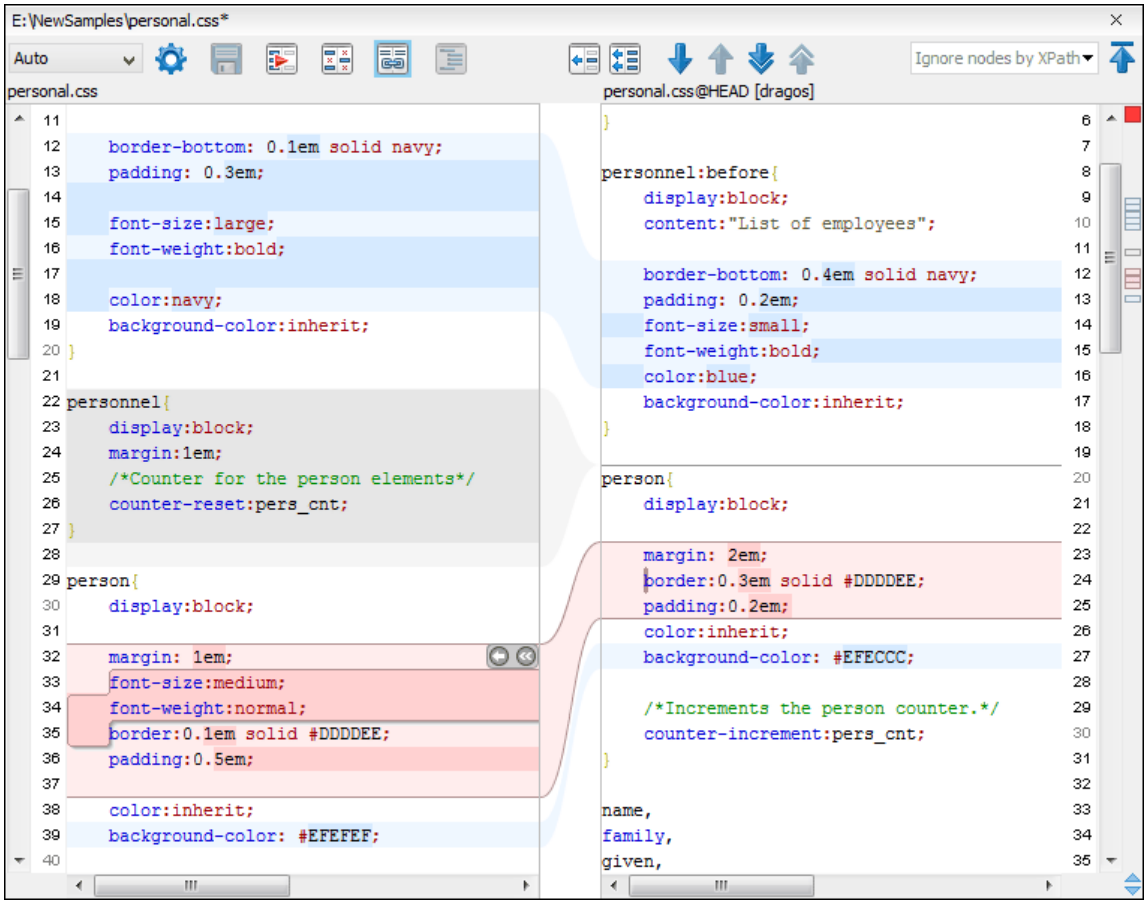
After you configure the options and click **OK**, the annotations will be computed and the **Annotations** view is displayed, where all the users that modified the selected resource will be presented, along with the specific lines and revision numbers modified by each user.

Note:
If the file has a very long history, the computation of the annotation data can take a long time to process.

Compare View

In the Oxygen XML Editor, there are three types of files that can be checked for differences: text files, image files and binary files. For the text files and image files you can use the built-in **Compare** view. This view is automatically opened if you select two files and use the **Compare with > Each Other** action in the contextual menu.

Figure 751. Compare View



At the top of each of the two editors, there are presented the name of the open file, the corresponding SVN revision number (for remote resources) and the author who committed the associated revision.

When comparing text, the differences are computed using a *line differencing algorithm*. The view can be used to show the differences between two files in the following cases:

- After obtaining the outgoing status of a file with a **Refresh** operation, the view can be used to show the differences between your working file and the pristine copy. In this way you can find out what changes you will be committing.
- After obtaining the incoming and outgoing status of the file with the **Synchronize** operation, you can examine the exact differences between your local file and the *HEAD* revision file.
- You can use the **Compare view** from the **History view** to compare the local file and a selected revision or compare two revisions of the same file.

The Compare view contains two editors. Edits are allowed only in the left editor and only when it contains the working copy file. To learn more about how the view can be used, see View Differences *(on page 2928)*.

Compare View Toolbar

The toolbar of the **Compare** view contains the operations that can be performed on the source and target files.

Figure 752. Compare View Toolbar

The following actions are available:

Algorithm

The algorithm to be used for performing a comparison. The following options are available:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** comparison mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

 **Save action**

Saves the content of the left editor when it can be edited.

 **Perform Files Differencing**

Looks for differences between the two files displayed in the left and right side panels.

 **Ignore Whitespaces**

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces.

 **Synchronized scrolling**

Toggles synchronized scrolling. When toggled on, a selected difference can be seen in both panels.

 **Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on macOS))**

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences.

Note:
When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

 **Copy Change from Right to Left**

Copies the selected difference from the file in the right panel to the file in the left panel.

 **Copy All Changes from Right to Left**

Copies all changes from the file in the right panel to the file in the left panel.

 **Next Block of Changes (Ctrl + Period (Command + Period on macOS))**

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

> **Note:**
> A change block groups one or more consecutive lines that contain at least one change.

 **Previous Block of Changes (Ctrl + Comma (Command + Comma on macOS))**

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

 **Next Change (Ctrl + Shift + Period (Command + Shift + Period on macOS))**

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

 **Previous Change (Ctrl + Shift + Comma (Command + Shift + M on macOS))**

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Ignore Nodes by XPath

You can use this text field to enter an XPath expression *(on page 2117)* to ignore certain nodes from the comparison. It will be processed as XPath version 2.0. You can also enter the name of the node to ignore all nodes with the specified name (for example, if you want to ignore all ID attributes from the document, you could simply enter `@id`). This field is only available when comparing XML documents using the **XML Fast** or **XML Accurate** algorithms.

> **Note:**
> If an XPath expression is specified in the **Ignore nodes by XPath** option *(on page 297)* in the **Diff / File Comparison** preferences page, that one is used as a default when the application is started. If you then enter an expression in this field on the toolbar, this one will be used instead of the default. If you delete the expression from this field, neither will be used.

 **First Change (Ctrl + B (Command + B on macOS))**

Jumps to the first change.

Most of these actions are also available from the Compare *(on page 2896)* menu.

Image Preview

You can view your local files by using the built-in **Image Preview** component. The view can be accessed from the Working copy view *(on page 2990)* or from the Repository view *(on page 2985)*. It can also be used from the History view *(on page 3005)* to view a selected revision of a image file.

Only one image file can be opened at a time. If an image file is opened in the *Image preview* and you try to open another one it will be opened in the same window. Supported image types are *GIF*, *JPEG/JPG*, *PNG*, *BMP*. Once the image is displayed in the **Image Preview** panel using the actions from the contextual menu, you can scale the image at its original size (**1:1** action) or scale it down to fit in the view's available area (**Scale to fit** action).

Compare Images View

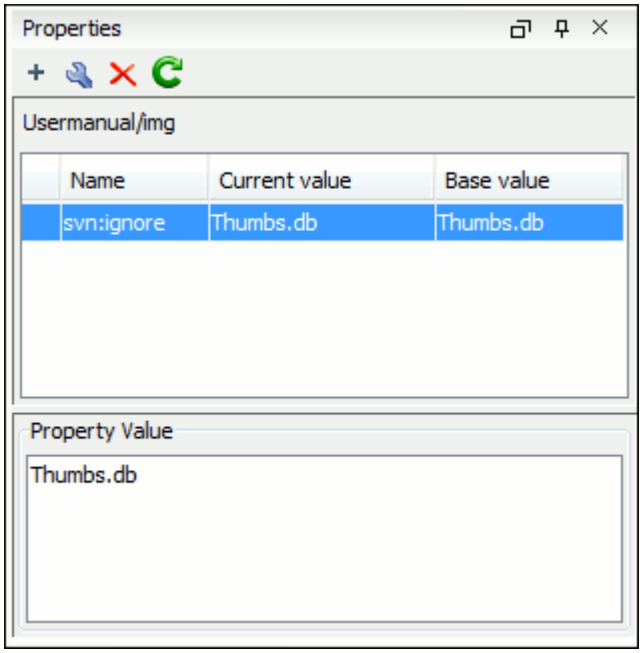
The images are compared using the **Compare Images** view. This view is automatically opened if you select two image files and use the **Compare with > Each Other** action in the contextual menu. The images are presented in the left and right part of the view, scaled to fit the available area. You can use the contextual menu actions to scale the images at their original size or scale them down to fit the view's available area.

The supported image types are: *GIF*, *JPG / JPEG*, *PNG*, *BMP*.

Properties View

The properties view presents Apache Subversion™ properties for the currently selected resource from either the **Working Copy** view or the **Repositories** view. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 753. Properties View



The table includes four columns:

- **State** - Can be one of the following:
  - *(empty)* - Normal unmodified property (same current and base values)
  - * *(asterisk)* - Modified property (current and base values are different)
  - + *(plus sign)* - New property
  - - *(minus sign)* - Removed property
- **Name** - The property name.
- **Current value** - The current value of the property.
- **Base value** - The base (original) value of the property.

svn:externals Property

The `svn:externals` property can be set on a folder or a file. In the first case, it stores the URL of a folder from another repository *(on page 3002)*.

In the second case, it stores the URL of a file from another repository. The external file will be added into the working copy as a versioned item. There are a few differences between directory and external file:

- The path to the external file must be in a working copy that is already checked out. While external directories can place the external directory at any depth and it will create any intermediate directories, external files must be placed into a working copy that is already checked out.
- The external file URL must be in the same repository as the URL that the external file will be inserted into (inter-repository external files are not supported).
- While commits do not descend into an external directory, a commit in a directory containing an external file will commit any modifications to the external file.

The difference between a normal versioned file and an external file is that external files cannot be moved or deleted (the `svn:externals` property must be modified instead. However, external files can be copied).

An external file is displayed as an X in the switched status column.

Toolbar / Contextual Menu

The properties view toolbar and contextual menu contain the following actions:

- **Add a new property** - This button invokes the *Add property* dialog box where you can specify the property name and value.
- **Edit property** - This button invokes the *Edit property* dialog box where you can change the property value and also see its original(base) value.
- **Remove property** - This button will prompt a dialog box to confirm the property deletion. You can also specify if you want to remove the property recursively.
- **Refresh** - This action will refresh the properties for the current resource.

Console View

The **Console View** shows the traces of all the actions performed by the application. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Part of the displayed messages mirror the communication between the application and the Apache Subversion™ server. The output is expressed as subcommands to the Subversion server and simulates the Subversion command-line notation. For a detailed description of the Subversion console output read the **SVN User Manual**.

The view has a simple layout, with most of its space occupied by a message area. On its right side, there is a toolbar holding the following buttons:

 **Clear**

Erases all the displayed messages.

 **Lock scroll**

Disables the automatic scrolling when new messages are appended in the view.

The maximum number of lines displayed in the console (length of the buffer) can be modified in the Preferences *(on page 290)* page. By default, this value is set to 100.

Dynamic Help View

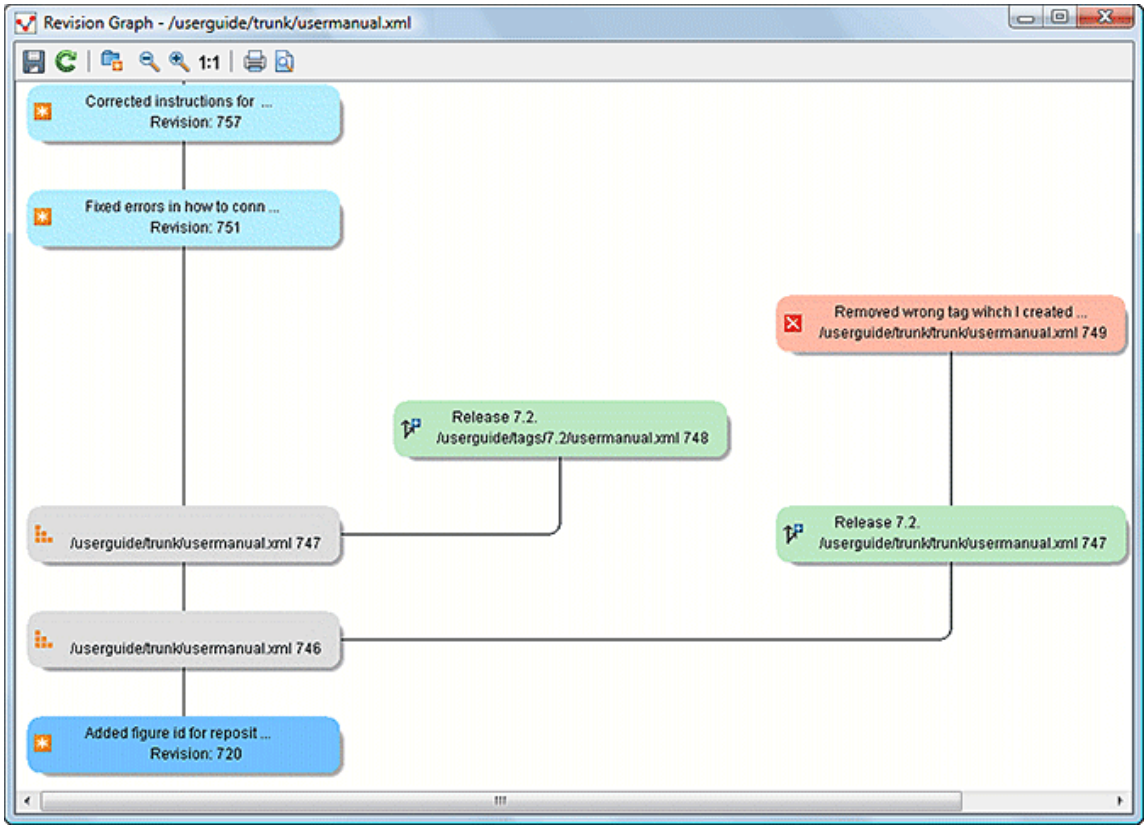
Dynamic Help view is a help window that changes its content to display the help section that is specific to the currently selected view. As you change the focused view, you can read a short description of it and its functionality. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Revision Graph of an SVN Resource

The history of an SVN resource can be watched on a graphical representation of all the revisions of that resource together with the tags in which the resource was included. The graphical representation is identical to a tree structure and very easy to follow.

The graphical representation of a resource history is invoked with the  **Revision graph** action available on the right-click menu of an SVN resource in the *Working Copy* view *(on page 2990)* and the *Repository* view *(on page 2985)*.

Figure 754. Revision Graph of a File Resource



In every node of the revision graph an icon and the background color represent the type of operation that created the revision represented in that node. The commit message associated with that revision, the repository path, and the revision number are also contained in the node. The tooltip displayed when the mouse pointer hovers over a node specifies the URL of the resource, the SVN user who created the revision of that node, the revision number, the date of creation, the commit message, the modification type and the affected paths *(on page 2918)*.

The types of nodes used in the graph are:

Added resource

The icon for a new resource added to the repository and a green background.

Copied resource

The icon for a resource copied to other location (for example, when an SVN tag is created and a green background).

Modified resource

The icon for a modified resource and a blue background.

Deleted resource

The icon for a resource deleted from the repository and a red background.

Replaced resource

The icon for a resource removed and replaced with another one on the repository and an orange background.

Indirect resource

The icon for a revision from where the resource was copied or an indirectly modified resource, that is a directory where a resource was modified and a gray background. The *Modification type* field of the tooltip specifies how that revision was obtained in the history of the resource.

A directory resource is represented with two types of graphs:

Simplified graph

Lists only the changes applied directly to the directory;

Complete graph

Lists also the indirect changes of the directory resource, that is the changes applied to the resources contained in the directory.

Figure 755. Revision Graph of a Directory (Direct Changes)

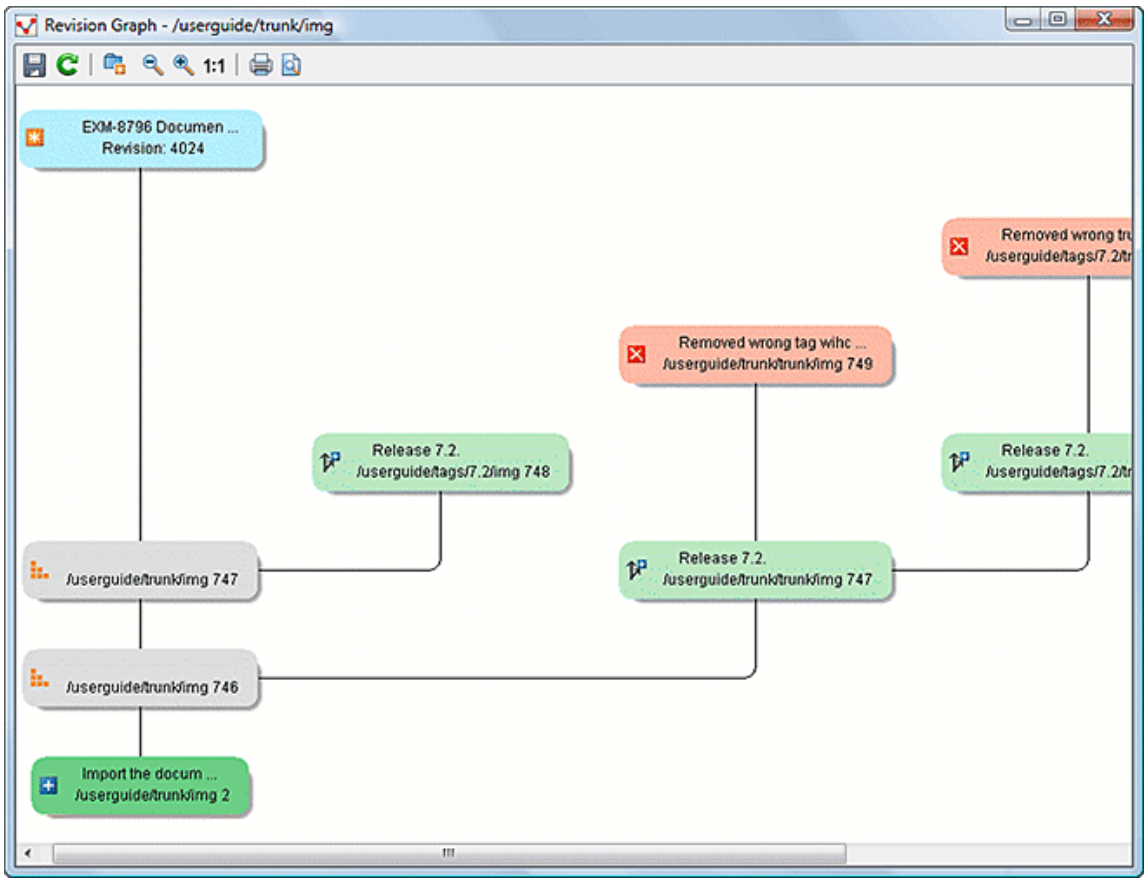


Figure 756. Revision Graph of a Directory (Including Indirect Changes)

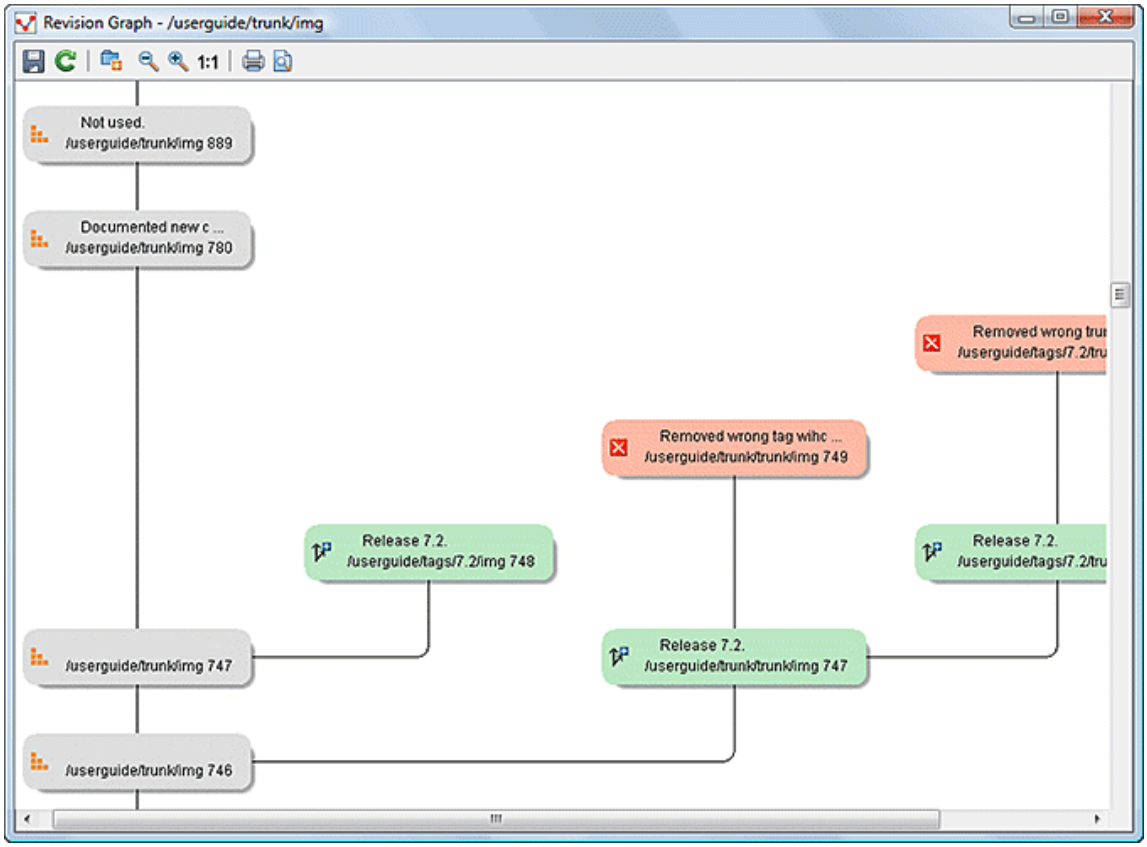


The **Revision graph** toolbar contains the following actions:

Save as image

Saves the graphical representation as image. For a large revision graph you have to set more memory in the startup script *(on page 348)*. The default memory size is not enough when there are more than 100 revisions that are included in the graph.

/ Show/Hide indirect modifications

Switches between simplified and complete graph.

Zoom In

Zooms in the graph.

Zoom Out

Zooms out the graph. When the font reaches its minimum size, the graph nodes will display only the icons, leading to a very compact representation of the graph.

1:1 Reset scale

Resets the graphical scale to a default setting.

Print

Prints the graph.

Print preview

Offers a preview of the graph to allow you to check the information to be printed.

The contextual menu of any of the graph nodes contains the following actions:

Open

Opens the selected revision in the editor panel. Available only for files.

Open with

Opens the selected revision in the editor panel. Available only for files.

Save as

Saves the file that had the revision graph generated, based on the selected node revision.

Copy to

Copies to the repository the item whose revision graph is displayed, using the selected revision.

Note:
This action can be used to resurrect deleted items also.

Compare with HEAD

Compares the selected revision with the HEAD revision and displays the result in the diff panel. Available only for files.

Show History

Displays the history of the resource in the History view *(on page 3005)*. Available for both files and directories.

Check out

Checks out *(on page 2916)* the selected revision of the directory. Available only for directories.

Export

Opens the **Export** dialog box *(on page 2980)* that allows you to configure options for exporting a folder from the repository to the local file system.

When two nodes are selected in the revision graph of a file the right-click menu of this selection contains only the **Compare** for comparing the two revisions corresponding to the selected nodes. If the resource that had the revision graph built is a folder then the right-click menu displayed for a two nodes selection also contains the **Compare** action but it computes the differences between the two selected revisions as a set of directory changes. The result is displayed in the Directory Change Set *(on page 3010)* view.

Attention:
Generating the revision graph of a resource with many revisions may be a slow operation. You should enable caching for revision graph actions so that future actions on the same repository will not request the same data again from the SVN server, which will finish the operation much faster.

Oxygen XML Editor SVN Preferences

The options used in the SVN client are saved and loaded independently from the Oxygen XML Editor options. However, if Oxygen XML Editor cannot determine a set of SVN options to be loaded at startup, some of the preferences are imported from the XML Editor options (such as the License key and HTTP Proxy settings).

There is also an additional set of preferences applied to the SVN client that are set in global SVN files. There are two editing actions available in the **Global Runtime Configuration** submenu of the **Options** menu. These actions, **Edit 'config' file** and **Edit 'servers' file**, contain parameters that act as defaults applied to all the SVN client tools that are used by the same user on their login account.

Entering Local Paths and URLs

The Oxygen XML Editor includes a variety of option configuration pages or wizards that contain text boxes where you specify paths to local resources or URLs of items inside remote repositories. The Oxygen XML Editor provides support in these text boxes to make it easier to specify these paths and URLs.

Local Item Paths

The text boxes used for specifying local item paths support the following:

- *Absolute Paths* - In most cases, the Oxygen XML Editor expects absolute paths for local file system items.
- *Relative Paths* - The Oxygen XML Editor only accepts relative paths in the form `~[/...]`, where `~` is the user home directory.
- *Path Validation* - Oxygen XML Editor validates the path as you type and invalid text becomes red.
- *Drag and Drop* - You can drag files and folders from the file system or other applications and drop them into the text box.
- *Automatic Use of Clipboard Data* - If the text box is empty when its dialog box is opened, any data that is available in the system clipboard is used, provided that it is valid for that text box.

Repository Item URLs

- *Local Repository Paths* - You can use local paths (absolute or relative) to access local repositories. When you use the **Browse** button, the Oxygen XML Editor will convert the file path to a `file://` form of URL, provided that the location is a real repository.
  - *Absolute Paths* - In most cases, the Oxygen XML Editor expects absolute paths for local file system items.
  - *Relative Paths* - The Oxygen XML Editor only accepts relative paths in the form `~[/...]`, where `~` is the user home directory.
- *Peg Revisions* - For URL text boxes found inside dialog boxes where you are pulling information from the repository, you can use peg revisions at the end of the URLs *(on page 3027)* (for example, `URL@rev1234`).

Note:
If you try to use a *peg revision* number in a dialog box where you are sending information to the repository then the peg revision number will become part of the name of the item rather than searching for the specified revision. For example, in the URL `http://host/path/inside/repo/item@100`, the item name is considered to be `item@100`.

Tip:
You can even use *peg revisions* with local repository paths. For example, `C:\path\to\local\repo@100` will be converted to `file:///C:/path/to/local/repo@100` and the **Repository browser** will display the content of the local repository as it is at revision `100`.

- *URL Validation* - Oxygen XML Editor validates the URLs as you type and invalid text becomes red. Even paths to local repositories are not accepted unless using the **Browse** button to convert them to valid URLs.
- *Drag and Drop* - You can drag URLs from other applications or text editors and drop them into the URL text box. You can also drag folders that point to local repositories, from the local file system or from other applications, and they are automatically converted to valid `file://` type URLs.
- *Automatic Use of Clipboard Data* - If the URL text box is empty when its dialog box is opened, any data that is available in the system clipboard is used, provided that it is valid for that text box. Even valid local paths will be automatically converted to `file://` type URLs.

Note:
The text boxes that are in the form of a combo box also allow you to select previously used URLs, or URLs defined in the **Repositories** view.

Technical Issues

This section contains special technical issues found during the use of Syncro SVN Client.

Authentication Certificates Not Saved

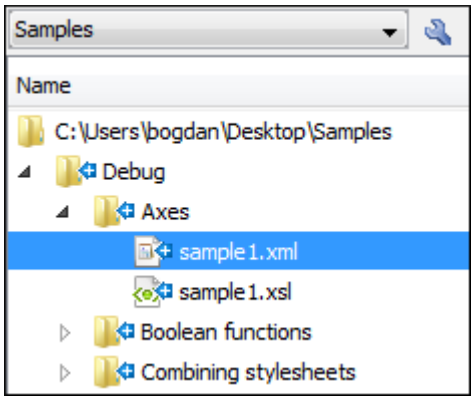
If Syncro SVN Client prompts you to enter the authentication certificate, although you already provided it in a previous session, then you should make sure that your local machine user account has the necessary rights to store certificate files in the *Subversion* configuration folder (write access to *Subversion* folder and all its subfolders). Usually, it is located in the following locations:

- Windows: `[HOME_DIR]\AppData\Roaming\Subversion`
- macOS and Linux: `[HOME_DIR]/.subversion`

Updating Newly Added Resources

When you want to get a resource that is part of a newly created structure of folders from the repository, you need to also get its parent folders.

Figure 757. Incoming Changes



Syncro SVN Client allows you to choose how you want to deal with the entire structure from that moment onwards:

Update ancestor directories recursively

This option brings the entire newly added folders structure into your working copy. In this case, the update time depends on the total number of newly incoming resources, because of the full update operation (not updating only selected resource).

Update selected files only (leave ancestor directories empty)

This option brings a skeleton structure composed of the resource's parent folders only, and the selected resource at the end of the operation. All of the parent directories will have depth set to *empty* in your working copy, thus subsequent **Synchronize** operations will not report any remote modifications in those folders. If you need to update the folders to full-depth, you can use the **Update to revision/depth** action *(on page 2999)* from the working copy view.

Accessing Old Items from a Repository

Usually, you point to an item from a repository using a URL. However, sometimes this might not be enough because the URL alone might point to a different item than the one you want and a *peg revision* is needed.

A Subversion repository tracks any change made to its items by using *revisions*, which contain information such as the name of the author who made the changes, the date when they were made, and a number that uniquely identifies each of them. Over time, an item from a specific location in a repository evolves as a result of committing changes to it. When an item is deleted, its entire life cycle (all changes made to it from the moment it was created) remains recorded in the history of the repository. If a new item is created, with the same name and in the same location of the repository as a previously existing one, then both items are identified by the same URL even though they are located in different time frames. This is when a *peg revision* comes in handy. A *peg revision* is nothing more than a normal revision, but the difference between them is

made by their usage. Many of the Subversion commands also accept a peg revision as a way to precisely identify an item in time, beside an *operative revision* (the revision regarding the used command).

Example:

To illustrate an example, consider the following:

- A new repository file `config` was created, identified by the URL `http://host.com/myRepository/dir/config`.
- The file has been created at revision `10`.
- Over time, the file was modified by committing revisions `12, 15, 17`.

To access a specific version of the file identified by the `http://host.com/myRepository/dir/config` URL, you need to use a corresponding revision (the operative revision):

- If a revision number is used that is lower than `10`, an error is triggered, because the file has not been created yet.
- If a revision number is used that is between `10` and `19`, the specific version you are interested in would be obtained.

> **Note:**
> Although the file was modified in revisions `12, 15, 17`, it existed in all revisions between `10` and `19`. Starting with a revision where the file is modified, it has the same content across all revisions generated in the repository until another revision where it is modified again.

At this point, the file is deleted, creating revision `20`. Now, no version of the file can be accessed because it no longer exists in the latest repository revision. This is due to the fact that Subversion automatically uses the `HEAD` revision as a peg revision (it assumes any item currently exists in the repository if not instructed otherwise). However, using any of the revision numbers from the `10-19` interval (when the file existed) as a peg revision (beside the operative revision), will help Subversion to properly identify the time frame when the file existed, and access the file version corresponding to the operative revision. If you use a revision number greater than `19`, this will also trigger an error.

Continuing the example, suppose that at revision `30`, a directory called `config` is created in the same repository location as the deleted file. This means that the new directory will be identified by the same repository address: `http://host.com/myRepository/dir/config`. If you only use this URL in any Subversion command, you will access the new directory. You will also access the same directory if you use any revision number equal to or greater than `30` as peg revision. However, if you are interested in accessing an old version of the previously existing file, then you must use one of the revisions that existed (`10-19`), as a peg revision, similar to the previous case.

Checksum Mismatch Error

A *Checksum Mismatch* error could happen if an operation that sends or retrieves information from the repository to the working copy is interrupted. This means that there is a problem with the synchronization between a local item and its corresponding remote item.

If you encounter this error, try the following:

1. Identify the parent directory of the file that caused the error (the file name should be displayed in the error message).

   Note:
   If the parent directory is the root of the working copy or if it contains a large amount of items it is recommended that you check out the working copy again, rather than continuing with the rest of this procedure.

2. Identify the current depth *(on page 2992)* of that directory.
3. Update the parent directory using the **Update to revision/depth** action that is available from the contextual menu or the **Working copy** menu. For the **Depth** option, select **This folder only (empty)**.

   Warning:
   If you have files with changes in this directory, those changes could be lost. You should commit your changes or move the files to another directory outside the working copy prior to proceeding with this operation.

4. After clicking **OK** the contents of the directory will be erased and the directory is be marked as having an *empty* depth *(on page 2992)*.
5. Once again, update the same directory using the **Update to revision/depth** action. This time, for the **Depth** option, select the depth that was previously identified in step 2.
6. If you moved modified files to another directory outside the working copy, move them back to the original location inside the working copy.

If this procedure does not solve the error, you need to check out the working copy again and move possible changes from the old working copy to the new one.

External Tools

A command-line tool can be started in the Oxygen XML Editor user interface as if from the command line of the operating system shell. Oxygen XML Editor offers you the option of integrating such a tool by specifying just the command line for starting the executable file and its working directory. To integrate such a tool, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **External Tools** *(on page 301)* (or select **Configure** from the **Tools > External Tools** menu).

The **External Tools** preferences page *(on page 301)* presents a list of the external tools that have been configured. Once a tool has been configured *(on page 301)*, you can open it by selecting it from the **Tools > External Tools** menu or from the **External Tools** drop-down menu on the toolbar (the **Tools** toolbar needs to be selected in the **Configure Toolbars** dialog box *(on page 374)*). You can also assign a keyboard shortcut *(on page 303)* to be used to launch the tool.

If the external tool is applied on one of the files opened in Oxygen XML Editor, the **Save all files before calling external tools** option *(on page 210)* (in the **Save** preference page) should be selected so that all edited files are automatically saved when an external tool is applied.

When an external tool is launched, the icon on the toolbar changes to a stop icon ( ) and you can use this button to stop the tool. When the tool has finished running (or you close it), the icon changes back to the original icon ( ).

Note:
Even though you can stop the external tool by invoking the stop action while it is running, that does not necessarily mean it will also stop the processes spawned by that external tool. For instance, if you stop an external tool that runs a batch file, the batch may be stopped but without actually stopping the processes that the batch was running at that time.

Example: Integrating the Ant Tool

This is an example procedure for integrating the Ant build tool into Oxygen XML Editor:

1. Download and install *Apache Ant (on page 3417)* on your computer.
2. Test your *Ant* installation from the command-line interface in the directory where you want to use *Ant* from. For example, run the `clean` target of your `build.xml` file `C:\projects\XMLproject\build.xml`:
   ```
   ant clean
   ```
3. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **External Tools** (or select **Configure** from the **Tools > External Tools** menu).
4. Click the **New** button to create a new external tool entry and enter the following information:
   - **Name** - For example, `Ant tool`.
   - **Working directory** - For example, `C:\projects\XMLproject`.
   - **Command line** - For example, `"C:\projects\XMLproject\ant.bat" clean`.
5. Click **OK** to add the new tool to the list of external tools.
6. Run the tool from **Tools > External Tools > Ant tool**. You can see the output in the system console:
   ```
   Started: "C:\projects\XMLproject\ant.bat" clean
   Buildfile: build.xml

   clean:
   ```

```
[echo] Delete output files.
[delete] Deleting 5 files from C:\projects\XMLproject

BUILD SUCCESSFUL
Total time: 1 second
```

21.

Troubleshooting

This section provides a collection of common performance and other types of problems that might be encountered when using Oxygen XML Editor, along with their possible solutions.

Performance Problems and Solutions

This section contains solutions for some common performance problems that may appear when running Oxygen XML Editor.

Related Information:

Documents with Long Lines *(on page 481)*
Loading Large Documents *(on page 479)*
External Tools *(on page 3029)*

Display Problems on Linux or Solaris

Problem

I experience display problems (such as screen freezes) on Linux or Solaris.

Cause

This is possibly a rendering problem with the off-screen pixmap support.

Solution

Add the following startup parameter *(on page 348)*: **-Dsun.java2d.pmoffscreen=false**.

Out of Memory on External Processes

Problem

Oxygen XML Editor throws an *Out Of Memory* error when trying to generate PDF output with the built-in Apache FOP processor.

Cause

The amount of allocated memory might be insufficient.

Solutions

- Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **XML > PDF Output > FO Processors**, and increase the value of the **Memory available to the Apache FOP** option *(on page 270)*.
- For external XSL-FO processors, XSLT processors, and external tools, the maximum value of the allocated memory is set in the command line of the tool using the **-Xmx** parameter set to the Java virtual machine.

Related Information:

Custom Engines Preferences *(on page 268)*

External Tools Preferences *(on page 301)*

How to Enable Debugging for FO Processor Transformations *(on page 1575)*

Too many nested apply-templates calls Error When Running a Transformation

Problem

I'm getting the error message **Too many nested apply-templates calls** when I try to transform my DocBook file to HTML using default Oxygen XML Editor DocBook to HTML transformation scenario.

Cause

Most likely, this is the result of a masked stack overflow error.

Solution

Try setting a new VM option with the value **-Xss4m**. You can also try to slowly increase this to larger values (e.g. **-Xss5m** or **-Xss6m**). Note that this consumes memory on a per thread basis (Oxygen XML Editor can have tens of threads), so using a very large value here can backfire and leave Oxygen XML Editor without memory.

Related Information:

Setting a Java Virtual Machine Parameter when Launching Oxygen XML Editor *(on page 348)*

Performance Issues with Large Documents

Problem

The performance of the application slows down considerably over time when working with large documents.

Cause

A possible cause is that the application needs more memory to run properly.

Solutions

- You can increase the maximum amount of memory available to Oxygen XML Editor by setting the **-Xmx** parameter in a configuration file *(on page 348)* that is specific to the platform that runs the application.

  Attention:
  The maximum amount of memory should be less than 75% of the physical amount of memory available on the machine. Otherwise, the operating system and other applications will have no memory available.

- When installed on a multiple user environment, each instance of Oxygen XML Editor will be allocated the amount stipulated in the memory value. To avoid degrading the general performance of the host system, ensure that the amount of memory available is optimally apportioned for each of the expected instances.

  Note:
  When starting Oxygen XML Editor from the icon created on the Start menu or Desktop in Windows (or from the shortcut created on the Linux desktop), the default maximum memory available to the application is set to 40% of the amount of physical RAM (but not more than 1 GB for 32-bit distributions or 4 GB for 64-bit distributions).

  When starting Oxygen XML Editor from a command-line script, the default maximum memory is 1 GB for 32-bit distributions or 4 GB for 64-bit distributions.

Performance Issues when Using Oxygen XML Editor with Remote Desktop

Problem

When trying to run Oxygen XML Editor in a Remote Desktop Protocol (RDP) environment, the performance is slow and choppy.

Cause

Running a standalone version of Oxygen XML Editor over a slow RDP connection may result in performance issues.

Solution

As a workaround, you try to run Oxygen XML Editor as an Eclipse plugin when working with a slow RDP connection.

Misc Problems and Solutions

This chapter presents common problems that may appear when running the application along with solutions for these problems.

Address Family Not Supported by Protocol Family

Problem

I have experienced the following error: *"Address Family Not Supported by Protocol Family; Connect"*. How do I solve it?

Cause

This seems to be an IPv6 connectivity problem. By default, the Java runtime used by Oxygen XML Editor prefers to create connections via IPv6, if the support is available. However, even though it is available in appearance, IPv6 sometimes happens to be configured incorrectly on some systems.

Solution

A quick solution for this problem is to set the `java.net.preferIPv4Stack` Java property to `true` (`java.net.preferIPv4Stack=true`), by following this procedure:

1. Create a file named `custom_commons.vmoptions` and on a single line, add `-Djava.net.preferIPv4Stack=true`. Then save the file and copy it to the Oxygen XML Editor installation folder (may need admin access).
2. Restart Oxygen XML Editor.
3. Make sure the procedure was successful by going to **Help > About > System properties** and check that the value of the `java.net.preferIPv4Stack` property is `true`.

Application Reports Errors During Startup After Installing a New Version

Problem

Sometimes, after installing a new version of Oxygen XML Editor, various errors are reported when the application starts.

Cause

This problem may occur if you install the application in a folder where an older version of the application was previously installed. Especially on macOS, there is a possibility for older resources and libraries from the previous application to remain in the installation folder and break the functionality of the newer version of the application.

Solution

Close the application and completely uninstall it *(on page 130)*, then install it again. The user-specific settings are saved in a separate folder in the user home directory so they will not be lost.

- On macOS, you can move the entire application installation folder to the **Trash**, then re-install.
- On Linux and Windows, you can uninstall using the facilities provided by the installer *(on page 130)*, then re-install.

If you intentionally want to load extra Java libraries with Oxygen XML Editor, you have the following choices:

- If the libraries are necessary for XSLT transformations, each XSLT transformation scenario has an **Extensions** button that allows you to reference the libraries directly from the transformation scenario.
- If the libraries are necessary for database connections, you can configure them when you define the data sources.
- You can add a plugin in Oxygen XML Editor that contributes libraries to the global libraries list. The plugin can be distributed as an add-on. An example of such a plugin can be found here: https://github.com/oxygenxml/oxygenxml.xlsx.import.
- In the Oxygen XML Editor `lib` folder, there is a file called `libraries.list`. You can edit that file and add the names of the extra libraries present in the folder. You can also choose to delete that `libraries.list` completely if you want to inhibit the libraries checking completely.

Application Takes Several Minutes to Start

Problem

Oxygen XML Editor seems to take an abnormally long amount of time to start.

Cause

Some anti-virus software can cause Java applications, such as Oxygen XML Editor, to start very slowly due to scanning compressed archives (such as the *JAR* libraries that all Java applications use).

Solution

A possible solution is to add the Oxygen XML Editor folder to the list of exceptions in the anti-virus software settings.

Archive Distribution Fails to Run on macOS 10.12 (Sierra)

Problem

For versions prior to 18.1, the classic archive distributions of Oxygen XML Editor (`.zip` or `.tar.gz`) fail to run on macOS 10.12 (Sierra).

Cause

This happens because the archives get quarantined and macOS 10.12 (Sierra) treats quarantined apps differently than older versions and isolates them from their parent folder at launch. If Oxygen XML Editor was already installed when you upgraded to macOS 10.12 (Sierra), there are no problems.

Solution

If Oxygen XML Editor was not already installed, or you need to reinstall an older version (prior to version 18.1), the quarantine flag must be removed for the entire content of the Oxygen XML Editor installation directory or the individual applications. To resolve this issue, follow these steps:

1. Open a *Terminal* window and change the directory to the folder where Oxygen XML Editor is located.
2. Run the following command:

   ```
   xattr -dr com.apple.quarantine oxygen/
   ```

   where "*oxygen*" is the actual name of the Oxygen XML Editor directory.

   If Oxygen XML Editor is in a location that requires administrator privileges for write access, you need to run the command from an administrator account and prefix the command with `sudo`. You will then be prompted to enter your password.

Blank Window is Shown When Starting the App Over an RDP Connection on Linux

Problem

When starting Oxygen XML Editor or its installer on *Linux*, a blank window is displayed when started over an RDP connection.

Cause

Oxygen XML Editor and its installer are Java Swing apps that require a 24 bit color depth from the X server.

Solution

1. If you are using *xrdp*, find the `/etc/xrdp/xrdp.ini` file.
2. Uncomment the `xserverbpp=24` line.
3. Save your files and close all the apps (the subsequent step will terminate your remote session so you could lose your progress if you do not save your files first).
4. Restart the *xrdp* service:

   ```
   sudo systemctl restart xrdp.service
   ```

Note:
Alternatively, you can try setting `max_bpp=24` in the same `/etc/xrdp/xrdp.ini` file.

Cannot Connect to SVN Repository from Repositories View

Problem

I cannot connect to an SVN repository from the **Repositories** view of SVN Client. How can I find more details about the error?

Solution

First check that you entered the correct URL of the repository in the **Repositories** view. Also, check that an SVN server is running on the server machine specified in the repository URL and is accepting connections

from SVN clients. You can check that the SVN server accepts connections with the command-line SVN client from CollabNet.

If you try to access the repository with an `svn+ssh` URL, also check that an SSH server is running on port 22 on the server machine specified in the URL.

If the above conditions are verified and you cannot connect to the SVN repository, generate logging files on your computer and send them to support@oxygenxml.com. For generating the logging files, follow these steps:

1. Create a text file called `logback.xml` in the application installation folder with the following content:

```
<configuration>
    <appender name="R2" class="ch.qos.logback.core.rolling.RollingFileAppender">
        <file>${user.home}/Desktop/oxygenLog/oxygen.log</file>
        <rollingPolicy class="ch.qos.logback.core.rolling.FixedWindowRollingPolicy">
            <fileNamePattern>${user.home}/Desktop/oxygenLog/oxygen%i.log.gz</fileNamePattern>
            <minIndex>1</minIndex>
            <maxIndex>20</maxIndex>
        </rollingPolicy>
        <triggeringPolicy class="ch.qos.logback.core.rolling.SizeBasedTriggeringPolicy">
            <maxFileSize>12MB</maxFileSize>
        </triggeringPolicy>
        <encoder>
            <pattern>%r %marker %p [ %t ] %c - %m%n</pattern>
        </encoder>
    </appender>

    <root level="debug">
        <appender-ref ref="R2" />
    </root>
</configuration>
```

2. Restart the application.
3. Reproduce the error.
4. Close the application.
5. Delete the `logback.xml` file because it might cause performance issues if you leave it in the installation folder.

Important:
The logging mode may severely decrease the performance of the application. Therefore, do not forget to delete the `logback.xml` file when you are done with the procedure.

Result: The resulting logging files are named `oxygen.log` and `oxygen#.log.qz` (for example, `oxygen.log`, `oxygen1.log.gz`, `oxygen2.log.gz`, etc.) and are located in the `Desktop\oxygenLog` folder.

Cannot Open Files from Desktop/Downloads/OneDrive on macOS

Problem

When using Oxygen XML Editor on *macOS*, the application cannot open files from Desktop/Downloads/OneDrive.

Cause

Sometimes, macOS shows a popup about allowing the application access to some special folders (e.g. Downloads or Desktop), and unless you explicitly agree, it will leave it unchecked (the app does not allowed access). The popup can go unnoticed and disappears after a while, so it is easy to overlook it and the application will not have access to that folder.

Solution

Go to the macOS **System preferences > Security & Privacey > Privacy tab > Files and Folders**. You should find *Oxygen* in that list and the folders you were prompted to access. Check the box for the folder (i.e. Downloads or Desktop), if there is one unchecked.

Note:
If that does not work, look at "Full Disk Access" from the same Privacy tab. Add *Oxygen* there so that it has full access. However, only use this method as a last resort.

Cannot Uninstall Oxygen XML Editor in Windows

Problem

When I try to uninstall Oxygen XML Editor in Windows, I get an error that says it cannot find the `files.log` file.

Cause

The *install4j* installer that is used by Oxygen XML Editor creates the `files.log` file during the installation process. If you cannot uninstall the product, then most likely something went wrong with this file during the installation process.

Solution

To solve this, simply reinstall the software in the same directory as the current installation. This will automatically uninstall the old version or overwrite it with a clean install. You should then be able to uninstall this new installation.

Compatibility Issue Between Java and Certain Graphics Card Drivers

Problem

Under certain settings, a compatibility issues can appear between Java and some graphics card drivers, which results in the text from the editor (in **Author** or **Text** mode) being displayed garbled.

Solution

If you encounter this problem, update your graphics card driver. Another possible workaround is, open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Appearance > Fonts**, and set the value of the **Text antialiasing** option *(on page 141)* to ON.

> **Note:**
> If this workaround does not resolve the problem, set the **Text antialiasing** option *(on page 141)* to other values.

Crash at Startup on Windows with an Error About the nvoglv32.dll File

Problem

I try to start Oxygen XML Editor on Windows but it crashed with an error message about *"Fault Module Name: nvoglv32.dll"*. What is the problem?

Cause

It is most likely an OpenGL driver issue.

Solution

This can be avoided by creating an empty file called `opengl32.dll` in the Oxygen XML Editor install folder (if you start Oxygen XML Editor with the shortcut created by the installer on the Start menu or on Desktop) or in the subfolder `bin` of the home folder of the Java virtual machine that runs Oxygen XML Editor (if you start Oxygen XML Editor with the `oxygen.bat` script). The home folder of the Java virtual machine that runs Oxygen XML Editor is the value of the `java.home` property that is available in the **System properties** tab of the **About** dialog box (**Help > About**).

Damaged File Associations on macOS

Problem

After upgrading macOS and Oxygen XML Editor, it is no longer associated to the appropriate file types (such as XML, XSL, XSD). How can I re-create the file associations?

Cause

The upgrade damaged the file associations in the LaunchService Database on your macOS machine.

Solution

You can rebuild the LaunchService Database with the following procedure. This will reset all file associations and rescan the entire file system searching for applications that declare file associations and collect them in a database used by Finder.

1. Find all the Oxygen XML Editor installations on your hard drive.
2. Delete them by dragging them to the Trash.
3. Clear the Trash.
4. Unpack the Oxygen XML Editor installation kit on your desktop.
5. Copy the contents of the archive into the folder `/Applications/Oxygen`.
6. Run the following command in a Terminal:

   ```
   /System/Library/Frameworks/CoreServices.framework/Versions/A/Frameworks/
   LaunchServices.framework/Versions/A/Support/lsregister -kill -r -domain local -domain system
   -domain user
   ```

7. Restart Finder with the following command:

   ```
   killall Finder
   ```

8. Create an XML or XSD file on your desktop. It should have the Oxygen XML Editor icon.
9. Double-click the file.
10. Accept the confirmation.

Result: When you start Oxygen XML Editor, the file associations should work correctly.

Details to Submit in a Request for Technical Support Using the Online Form

Problem

What details should I add to my request for technical support on the online form in the product website?

Solution

When completing a request for Technical Support using the online form, include as many details as possible about your problem. For problems where a simple explanation may not be enough for the Technical Support team to reproduce or address the issue (such as server connection errors, unexpected delays while editing a document, an application crash, etc.), you should generate log files and attach them to the problem report. In the case of a crash, you should also attach the crash report file generated by your operating system.

If the text content of an XML document you want to send to the support team contains sensitive or private information, you can use the **Randomize XML text content** action *(on page 53)* to create filler content. Before using this action, you need to copy the initial XML resources and save them in a separate folder. Otherwise, you might lose your original information.

To generate the Oxygen XML Editor log files, follow these steps:

1. Create a text file called `logback.xml` in the application installation folder, with the following content:

```
<configuration>
    <appender name="R2" class="ch.qos.logback.core.rolling.RollingFileAppender">
        <file>${user.home}/Desktop/oxygenLog/oxygen.log</file>
        <rollingPolicy class="ch.qos.logback.core.rolling.FixedWindowRollingPolicy">
            <fileNamePattern>${user.home}/Desktop/oxygenLog/oxygen%i.log.gz</fileNamePattern>
            <minIndex>1</minIndex>
            <maxIndex>20</maxIndex>
        </rollingPolicy>
        <triggeringPolicy class="ch.qos.logback.core.rolling.SizeBasedTriggeringPolicy">
            <maxFileSize>12MB</maxFileSize>
        </triggeringPolicy>
        <encoder>
            <pattern>%r %marker %p [ %t ] %c - %m%n</pattern>
        </encoder>
    </appender>

    <root level="debug">
        <appender-ref ref="R2" />
    </root>
</configuration>
```

2. Restart the application.
3. Reproduce the error.
4. Close the application.
5. Delete the `logback.xml` file because it might cause performance issues if you leave it in the installation folder.

> **Important:**
> The logging mode may severely decrease the performance of the application. Therefore, do not forget to delete the `logback.xml` file when you are done with the procedure.

Result: The resulting log files are named `oxygen.log` and `oxygen#.log.qz` (for example, `oxygen.log`, `oxygen1.log.gz`, `oxygen2.log.gz`, etc.) and are located in the `Desktop\oxygenLog` folder.

Dialog Boxes Cannot Be Resized on Mac

Problem

When using Oxygen XML Editor on *macOS Big Sur*, dialog boxes (for example the **Find/Replace** or **Preferences** dialog box) cannot be resized.

Cause

This is caused by an issue with resizing dialog boxes in Oxygen XML Editor on *macOS Big Sur* (and possibly later versions) causing crashes if the main application is in full screen mode.

Solution

Until this limitation is resolved in a future Oxygen XML Editor version, dialog boxes cannot be maximized or resized on *macOS Big Sur*.

DITA Map Transformation Fails (Cannot Connect to External Location)

Problem

DITA map (on page 3419) transformation fails because it cannot connect to an external location.

Solution

The transformation is run as an external Ant process so you can continue using the application as the transformation unfolds. All output from the process appears in the **DITA Transformation** tab.

The HTTP proxy settings are used for the Ant transformation, so if the transformation fails because it cannot connect to an external location, you can check the the **Proxy** preferences page *(on page 310)*

DITA Map WebHelp Transformation Fails (Duplicate Topic References Found)

Problem

DITA Map WebHelp transformation fails with a message that indicates duplicate topic references were found.

Cause

By default the WebHelp transformation uses the `force-unique` parameter set to **true** to force the transformation to create unique output files for each instance of a resource when a map contains multiple references to a single topic. However, there are cases when this feature does not work as expected and the duplicate topic references are not handled properly.

Solution

To solve this issue, you should manually set a unique `@copy-to` attribute on any duplicate topic reference that was not handled automatically by DITA-OT:

```
<map>
...
  <topicref href="../topics/MyTopic.dita"/>
...
  <topicref href="../topics/MyTopic.dita" copy-to="../topics/MyTopic-2.dita"/>
</map>
```

DITA-OT Transformation Takes a Long Time to Process

Problem

A DITA transformation takes an extremely long time to process (over an hour, for example).

Cause

Large delays in DITA-OT processing are usually caused by intensive disk operations, CPU usage, or connections to remote websites. The DITA-OT processing is very disk-intensive, each stage takes the entire content from the transformation temporary files folder, reads it, modifies it, and then writes it back.

Solution

There are several things you can try to troubleshoot this problem:

- If you are using a shared or remote drive, it is recommended to specify a local drive for the output and temporary files directory (edit the transformation scenario and in the **Output** tab, select a local directory for **Temporary files directory** and **Output directory**).
- If you want to test if the publishing has a problem downloading remote resources, you could disable the network adapter on the computer and then try to publish. The purpose is to see if the publishing finishes without any reported error about obtaining a certain HTTP resource.
- Using DTDs instead of XML Schemas is faster. This is because of a default transformation parameter called `args.grammar.cache` that only works for DTD-based DITA topics.
- You can increase the memory available to Oxygen XML Editor *(on page 3033)*. Sometimes, just increasing the amount of memory available to the DITA-OT process may be enough to lower the time necessary for the publishing to run.
- You can enable some logging to help you determine which stage in the process is taking a long time. Edit the transformation scenario and in the **Advanced** tab, enter **logger org.apache.tools.ant.listener.ProfileLogger** in the **Additional arguments** field. Then go to **Options > Preferences > DITA > Logging** and select **Always** for the **Show console output** option.
- You could try disabling antivirus applications since the publishing process is very disk intensive and certain antivirus application might slow down the process.
- If the published DITA map is part of a larger DITA project with lots of maps and topics, references from topics in the current map to topics in other sub-projects might result in problems resolving those references. You could look in the output folder to see if the number of HTML documents match the number of DITA topics in your map.

DITA PDF Transformation Fails

Problem

The DITA to PDF transformation fails.

Cause

To generate the PDF output, Oxygen XML Editor uses the DITA Open Toolkit. This process sometimes results in errors. For information about some of the most common errors, see DITA PDF Processing Common Errors *(on page 3314)*.

Solution

If your transformation fails, you can detect some of the problems that caused the errors by running the **Validate and Check for Completeness** action *(on page 3118)*. Depending on the options you select when you run it, this action reports errors such as topics referenced in other topics but not in the *DITA map (on page 3419)*, broken links, and missing external resources.

You can analyze the **Results** tab of the DITA transformation and search for messages that contain text similar to `[fop] [ERROR]`. If you encounter this type of error message, edit the transformation scenario you are using and set the **clean.temp** parameter to **no** and the **retain.topic.fo** parameter to **yes**. Run the transformation, go to the temporary directory of the transformation, open the `topic.fo` file and go to the line indicated by the error. Depending on the XSL FO context try to find the DITA topic that contains the text that generates the error.

If none of the above methods helps you, go to **Help > About > Components > Frameworks** and check what version of the DITA Open Toolkit you are using. Copy the whole output from the DITA-OT console output and either report the problem on the DITA User List or send it to support@oxygenxml.com.

Related Information:
How to Enable Debugging for FO Processor Transformations *(on page 1575)*

DITA PDF Processing Common Errors

There are cases when the PDF processing fails when trying to publish DITA content to a PDF file. This topic lists some of the common problems and possible solutions.

Problem: Cannot Save PDF

The FO processor cannot save the PDF at the specified target. The console output contains messages like this:

```
[fop] [ERROR] Anttask - Error rendering fo file:
C:\samples\dita\temp\pdf\oxygen_dita_temp\topic.fo
<Failed to open C:\samples\dita\out\pdf\test.pdf>
Failed to open samples\dita\out\pdf\test.pdf
.............
[fop] Caused by: java.io.FileNotFoundException:
C:\Users\default\Desktop\bev\out\pdf\test.pdf
(The process cannot access the file because it is being used by another process)
```

Solution: Cannot Save PDF

Such an error message usually means that the PDF file is already opened in a PDF reader application. The solution is to close the open PDF before running the transformation.

Problem: Table Contains More Cells Than Defined in Colspec

One of the DITA tables contains more cells in a table row than the defined number of `<colspec>` elements. The console output contains messages like this:

```
[fop] [ERROR] Anttask - Error rendering fo file:
D:\projects\eXml\samples\dita\flowers\temp\pdf\oxygen_dita_temp\topic.fo
<net.sf.saxon.trans.XPathException: org.apache.fop.fo.ValidationException:
The column-number or number of cells in the row overflows the number of
fo:table-columns specified for the table.
(See position 179:-1)>net.sf.saxon.trans.XPathException:
org.apache.fop.fo.ValidationException: The column-number or number of cells
in the row overflows the number of fo:table-columns specified for the table.
(See position 179:-1)
[fop]     at org.apache.fop.tools.anttasks.FOPTaskStarter.renderInputHandler
(Fop.java:657)
[fop]     at net.sf.saxon.event.ContentHandlerProxy.startContent
(ContentHandlerProxy.java:375)
.............
[fop] D:\projects\samples\dita\flowers\temp\pdf\oxygen_dita_temp\topic.fo ->
D:\projects\samples\dita\flowers\out\pdf\flowers.pdf
```

Solution: Table Contains More Cells Than Defined in Colspec

To resolve this issue, correct the `@colspec` attribute on the table that caused the issue. To locate the table that caused the issue:

1. Edit the transformation scenario and set the parameter `clean.temp` to `no`.
2. Run the transformation, open the `topic.fo` file in Oxygen XML Editor, and look in it at the line specified in the error message `(See position 179:-1)`.
3. Look around that line in the XSL-FO file to find relevant text content that you can use (for example, with the **Find/Replace in Files** action in the **DITA Maps Manager** view *(on page 3073)*) to find the original DITA topic where the table was generated.

Problem: Broken Link

There is a broken link in the generated XSL-FO file. The PDF is generated but contains a link that is not working. The console output contains messages like this:

```
[fop] 1248 WARN [ main ] org.apache.fop.apps.FOUserAgent -
Page 6: Unresolved ID reference "unique_4_Connect_42_wrongID" found.
```

Solution: Broken Link

To resolve this issue:

1. Use the **Validate and Check for Completeness** action available in the **DITA Maps Manager** view *(on page 3073)* to find such problems.
2. If you publish to PDF using a *DITAVAL* filter, select the same DITAVAL file in the **DITA Map Completeness Check** dialog box.
3. If the **Validate and Check for Completeness** action does not discover any issues, edit the transformation scenario and set the `clean.temp` parameter to `no`.
4. Run the transformation, open the `topic.fo` file in Oxygen XML Editor, and search for the *unresolved ID references* (for example: `unique_4_Connect_42_wrongID`).
5. Look in the `XSL-FO` file to find relevant text content that you can use (for example, with the **Find/Replace in Files** action in the **DITA Maps Manager** view *(on page 3073)*) to find the original DITA topic where the table was generated.

How to Enable Debugging for FO Processor Transformations *(on page 1575)*

DITA PDF CSS-based Processing Common Errors

For information about possible common errors that could be encountered when processing CSS-based DITA to PDF output, see the Troubleshooting section in the CSS-based PDF Customization guide *(on page 2099)*.

DITA to CHM Transformation Fails - Cannot Open File

Problem

The DITA to CHM transformation fails with the following error: `[exec] HHC5010: Error: Cannot open "fileName.chm". Compilation stopped.`

Cause

This error occurs when the CHM output file is opened and the transformation scenario cannot rewrite its content.

Solution

To solve this issue, close the CHM help file and run the transformation scenario again.

Tip:
It is a good practice to validate the *DITA map (on page 3419)* before executing the transformation scenario. To do so, run the **Validate and Check for Completeness** action *(on page 3118)*. Depending on the selected options, it will report detected errors, such as topics referenced in other topics (but not in the *DITA map*), broken links, and missing external resources.

Related Information:
DITA Map CHM (Compiled HTML Help) Transformation *(on page 3283)*

DITA to CHM Transformation Fails - Compilation Failed

Problem

The DITA to CHM transformation fails with the following error: `[exec] HHC5003: Error: Compilation failed while compiling fileName`.

Cause 1

One possible cause for this error is that the processed file does not exist.

Solution 1

To solve this issue, fix the file reference before executing the transformation scenario again.

Cause 2

Another possible cause for this error is that the processed file has a name that contains space characters.

Solution 2

To solve the issue, remove any spacing from the file name and run the transformation scenario again.

Tip:
It is a good practice to validate the *DITA map (on page 3419)* before executing the transformation scenario. To do so, run the **Validate and Check for Completeness** action *(on page 3118)*. Depending on the selected options, it will report detected errors, such as topics referenced in other topics (but not in the *DITA map*), broken links, and missing external resources.

Related Information:
DITA Map CHM (Compiled HTML Help) Transformation *(on page 3283)*

Fonts Installed in Windows Do Not Appear in Fonts Preferences Page

Problem

I installed a font in Windows and it does not appear in the list of available fonts in the **Preferences > Fonts** page *(on page 140)* (in the **Editor** section).

Cause

Oxygen XML Editor is a Java application and Java does not detect fonts that are installed at the user level. This most likely occurred because you installed the font via the **Install for me** option in Windows.

Solution

Reinstall the font using the **Install for all users** option in Windows. You will need Administrator privileges to access this option.

Format and Indent Fails

Problem

When I use the  **Format and Indent** function, I get an error message that indicates the *Format and Indent failed*.

Cause

This happens because the application tries to limit the exposure to XXE attacks so the parser blocks the expansion of system entities (the ones that are loaded from disk or from remote sources).

Solution

If you are in complete control of the XML documents (you manage or trust those who are creating and editing the documents), you can disable this particular check by selecting the **Enable system parameter entity expansion in other entity definitions** option *(on page 246)* in the **XML Parser** preferences page.

Handshake Failure Error When Accessing an HTTPS (SSL) Resource

Problem

When attempting to access an HTTPS (SSL) resource, I receive a **handshake_failure** error.

Cause

The issue is most likely due to the limitation of Java cryptography capabilities.

Solution

A solution might be to download and deploy *Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files 8 (for Java 11)*.

Warning:
It is possible that this may not be legal in your country. Be advised that you bare legal responsibility for activating unlimited strength Java cryptography capabilities, so you must have the legal right to use such cryptography (consult your export/import control counsel or attorney to determine the exact requirements for your jurisdiction).

To deploy it in Oxygen XML Editor, unpack the downloaded zip archive and move the two jar files (**local_policy.jar** and **US_export_policy.jar**) from **UnlimitedJCEPolicyJDK8** to the following directory, overwriting existing files:

- **Windows** - *[OXYGEN_INSTALL_DIR]*`/jre/lib/security`
- **Linux** - *[OXYGEN_INSTALL_DIR]*`/jre/lib/security`
- **macOS** - *[OXYGEN_INSTALL_DIR]*`/jre.bundle/Contents/Home/jre/lib/security`

Hunspell Spell Checker is Unusable on Your Platform Error

Problem

When trying to use the **Check Spelling** option, I receive the error **Hunspell spell checker is unusable on your platform. It has crashed the application in a previous session**.

Cause

There are instances where Oxygen XML Editor determines that an internal component (such as the spell checker) has crashed the application and disables that component from running in the future (to prevent a possible future crash).

Solution

To re-enable the spell checker component, follow these steps:

1. Close Oxygen XML Editor.
2. Open the `%APPDATA%\com.oxygenxml` folder and look for a file called something like **HunspellCrashGuard*.txt**. Delete that file.
3. Restart Oxygen XML Editor.

High Resolution Scaling Issues

Problem

I encounter scaling detection issues in a high resolution display (for example, some GUI components are too small).

Cause

This sometimes happens when using multiple displays with different resolutions because the application cannot detect the correct scaling setting.

Solution

You can use the `sun.java2d.uiScale` Java system property to instruct Java to use a particular scaling factor:

```
-Dsun.java2d.uiScale=1.5
```

High Resolution Scaling Issues on Linux

Problem

On Linux bundled with Oracle OpenJDK 11, Oxygen XML Editor does not automatically scale high-resolution images when using the system's scaling settings.

Cause

This happens because Java 11 does not detect the system scaling setting for HiDPI displays on Linux operating system.

Solution

In the Oxygen XML Editor installation folder, create a new file named **custom_commons.vmoptions**. Inside the file, manually add `-Dsun.java2d.uiScale=2`. This command instructs Java to use 2x (200%) scaling.

Images Appear Stretched Out in the PDF Output

Problem

When publishing XML content (DITA, DocBook, etc.), images are sometimes scaled up in the PDF outputs but are displayed perfectly in the HTML (or WebHelp) output.

Solution

PDF output from XML content is obtained by first obtaining an intermediary XML format called XSL-FO and then applying an XSL-FO processor to it to obtain the PDF. This stretching problem is caused by the fact that all XSL-FO processors take into account the DPI (dots-per-inch) resolution when computing the size of the rendered image.

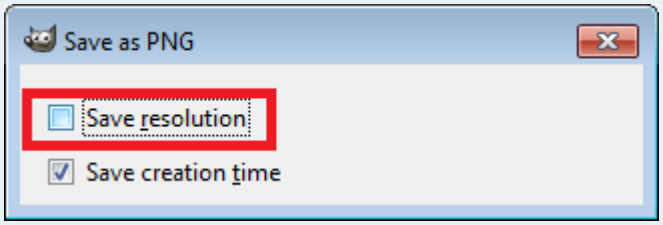
The PDF processor that comes out of the box with the application is the open-source Apache FOP processor. Here is what Apache FOP does when deciding the image size:

1. If the XSL-FO output contains width, height or a scale specified for the image `<external-graphic>` tag, then these dimensions are used. This means that if in the XML (DITA, DocBook, etc.) you set explicit dimensions to the image they will be used as such in the PDF output.
2. If there are no sizes (width, height or scale) specified on the image XML element, the processor looks at the image resolution information available in the image content. If the image has such a resolution saved in it, the resolution will be used and combined with the image width and height to obtain the rendered image dimensions.
3. If the image does not contain resolution information inside, Apache FOP will look at the FOP configuration file for a default resolution. The FOP configuration file for XSLT transformations that output PDF is located in the *[OXYGEN_INSTALL_DIR]*`/lib/fop.xconf`. DITA publishing uses the DITA Open Toolkit that has the Apache FOP configuration file located in [*DITA-OT-DIR*`/plugins/`

`org.dita.pdf2.fop/fop/conf/fop.xconf`. The configuration file contains two XML elements called `<source-resolution>` and `<target-resolution>`. The values set to those elements can be increased (usually a DPI value of 110 or 120 should render the image in PDF the same as in the HTML output).

The commercial **RenderX XEP** XSL-FO processor behaves similarly but as a fallback it uses 120 as the DPI value instead of using a configuration file.

Tip:
It is best to save your images without any DPI resolution information. For example, when saving a PNG image in the open-source GIMP image editor, you do not want to save the resolution.



This allows you to control the image resolution from the configuration file for all referenced images.

Increasing the Memory for the Ant Process

Problem

The Ant build process runs out of memory.

Solution

For details about setting custom JVM arguments to the Ant build process, see JVM Arguments *(on page 3302)*.

Java Virtual Machine (JVM) Crash on macOS

Problem

Oxygen XML Editor crashed the Java virtual machine or it could not start up on my macOS computer due to a JVM crash.

Cause

Usually it is an incompatibility between the JVM and a native library of the host system. More details are available in the crash log file generated by macOS and reported in the crash error message.

Solution

If this happens, it is best to send a copy of the logs via email to support@oxygenxml.com. Usually, the operating system will offer a prompt that allows you to see the logs. If not, you should be able to find the logs

in the Console app (**Applications > Utilities**, under **~/Library/Logs/DiagnosticReports**. They are usually named *JavaApplicationStub*.crash/.hang*.

JPEG CMYK Color Space Issues

Problem

JPEG images with the CMYK color profile and have the color profiles embedded in the image aren't rendered in the **Author** mode.

Solution

If the color profile information is missing from the JPEG image but you have the ICC file available, you can copy the `profileFileName.icc` to the `[OXYGEN_INSTALL_DIR]\lib` directory.

If the color space profile is missing, JPEG images that have the CMYK color space are rendered without taking the color profile into account. The **Unsupported Image Type** message is displayed above the image.

Keyboard Language Resets to Default on Windows

Problem

In Windows, I have set a specific language for my keyboard and while using Oxygen XML Editor, it keeps getting reset to the default language.

Cause

When multiple languages are enabled in Windows, the default shortcut key combination for switching the input language is **Left Alt + Shift**. Trying to use various shortcuts in Oxygen XML Editor that involves combinations of those two keys is probably resetting your input language to the default setting if you press those two keys without a third combination.

Solution

You can change the Windows shortcut keys that are assigned to the input language by going to the control panel and searching for the **Switch input languages** option. For example, in Windows, go to **Control Panel > Language > Advanced Setting**. In the **Switching input methods** section, click on **Change language bar hot keys**. Click the **Change Key Sequence** button. This opens a dialog box that allows you to switch the shortcut keys for the input language or keyboard layout.

Keyboard Shortcuts Do Not Work At All

Problem

The keyboard shortcuts listed in the Menu Shortcut Keys preferences page *(on page 303)* do not work.

Cause

Usually this happens when a special keyboard layout is set (in the operating system) that generates non-standard characters. For example, an extended Greek layout will generate special characters that are not present in the default Greek layout. This causes the Java virtual machine that runs the application to receive unexpected key codes.

Solution

Reset the keyboard layout to the standard layout for your particular language.

Keyboard Shortcuts Result in Unexpected Behavior

Problem

In some rare cases, using certain keyboard shortcuts listed in the Menu Shortcut Keys preferences page *(on page 303)* result in something different than what is listed in that preferences page.

Cause

This is usually caused by the operating system intercepting the keyboard shortcut. For example, certain applications or hardware drivers intercept certain keyboard shortcuts by default. Another example is if you have multiple input sources configured, the operating system might intercept shortcuts if they match the ones used to change between the input sources.

Solution

Assign a different keyboard shortcut for the particular action in the Menu Shortcut Keys preferences page *(on page 303)* or refer to documentation for your operating system or hardware equipment to see if there are options to change the behavior.

Mac Touch Bar Function Keys Do Not Work

Problem

I am using a Mac that has a Touch Bar but its function keys do not work in Oxygen XML Editor.

Causes

By default, the Touch Bar function keys are not enabled for Oxygen XML Editor.

Solution

To enable the Touch Bar function keys for Oxygen XML Editor, follow these steps:

1. Go to **System Preferences** and select **Keyboard**.
2. Click **Shortcuts**.

3. From the left sidebar, select **Function Keys**.
4. Click the **+** symbol, select **Oxygen** from the list of apps, and click **Add**.

Server Signature Mismatch Error

Problem

I receive an error indicating that *the current license was already activated on a License Server* or that the *License Server's Signature does not match*.

During the license activation process, the license key becomes bound to a particular license server deployment. This means that a code that uniquely identifies your license server deployment (called *Server Signature*) is sent to the **Oxygen** servers, which in turn will sign the license key. The *Server Signature* is computed from the list of network interfaces of the server where you deployed the license.

When starting the license server, if you receive an error stating that your *Server Signature* does not match, there are several possible causes:

Possible Cause 1

The license key was moved to a new server that hosts your license server.

Solution

Revert to your previous configuration.

Possible Cause 2

A new network interface was changed, added, or activated in the server that hosts your license server.

Note:
A specific example of when this could happen is if the Bluetooth or the WiFi module is activated/deactivated.

Solution

If reverting is not possible, contact the Oxygen support team.

Possible Cause 3

The license server was restarted from a different location as the previous restart. For example, some server configurations will have the Apache Tomcat server installed in a versioned folder (`/usr/local/apache-tomcat-V.V.V`) with a symbolic link to the typical folder (`/usr/local/tomcat`). The server can be restarted from either location, but it is recommended to always restart from the typical folder (`/usr/local/tomcat`) and always restart from the same location.

Solution

The server simply needs to always be restarted from the same location.

MSXML 4.0 Transformation Issues

Problem

When running a transformation scenario that uses the MSXML 4.0 transformer, I receive an error that looks like this:

```
Could not create the 'MSXML2.DOMDocument.4.0' object.
Make sure that MSXML version 4.0 is correctly installed on the machine.
```

Cause

It is likely that the latest MSXML 4.0 service pack is not installed on your computer.

Solution

To fix this issue, go to the Microsoft website and get the latest MSXML 4.0 service pack.

Navigation to a Web Page is Canceled when Viewing CHM on a Network Drive

Problem

When viewing a CHM on a network drive, I only see the TOC and an empty page that displays the message: **Navigation to the web page was canceled**.

Cause

This is actually normal behavior. The Microsoft viewer for CHM does not display the topics for a CHM open on a network drive.

Solution

As a workaround, copy the CHM file on your local system and view it there.

Out Of Memory Error When Opening Large Documents

Problem

I am trying to open a file larger than 100 MB in Oxygen XML Editor, but it runs out of memory (**OutOfMemoryError**).

Solution

You should make sure that the value of the **Optimize loading in the Text edit mode for files over** option *(on page 208)* is less than the size of your document. This will enable the optimized support for large documents.

If that fails and you still get an *Out Of Memory* error you should increase the memory available to Oxygen XML Editor *(on page 3033)*.

Other tips:

- Make sure that you close other files before opening the large file.
- You can set the default editing mode in the Preferences dialog box *(on page 178)*. The **Text** editing mode uses less memory than other editing modes.
- If the file is too large for the editor to handle, you can open it in for viewing in **Large File Viewer** *(on page 2839)*.

References Outside the Main DITA Map Folder

Problem

A reference to a DITA topic, *map*, or binary resource (for example, an image) that is located outside of the folder where the main *DITA map (on page 3419)* is located leads to problems when publishing the content using the DITA Open Toolkit.

Cause

DITA-OT often has trouble resolving references that are outside the directory where the published *DITA map* is found. By default, it does not even copy the referenced topics to the output directory.

Solution

To solve this, try one of the following solutions:

- Create another *DITA map* that is located in a folder path above all referenced folders and reference the original *DITA map* from this new map. Then transform this *DITA map* instead.
- Edit the transformation scenario and in the **Parameters** tab, change the value of the **fix.external.refs.com.oxygenxml** parameter to `true`. This parameter is used to specify whether or not the application tries to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content.

  > **Important:**
  > The **fix.external.refs.com.oxygenxml** parameter is only supported when the DITA-OT transformation process is started from Oxygen XML Editor or using the `transform` script.

- For PDF output, you can edit the transformation scenario and in the **Parameters** tab set the value of the **generate.copy.outer** parameter to `3`. This parameter specifies whether to generate output files for content that is not located in or beneath the directory containing the DITA map file. By setting the value

of this parameter to `3`, the transformation scenario shifts the output directory so that it contains all output for the publication.

> **Important:**
> This method is recommended for transformation scenarios that use an external DITA-OT.

Saxon 9.7 Transformer Issues

Problem

I have upgraded to Oxygen XML Editor version 19.0 (which comes bundled with Saxon 9.7) and I am experiencing issues when trying to use the Saxon 9.7 transformer. Is it possible to use the Saxon 9.6 transformer with Oxygen XML Editor version 19.0 or later?

Solution

There is a plugin available that can be installed and it allows you to use Saxon 9.6. To install it, follow these instructions:

1. Go to **Help > Install new add-ons** to open an add-on selection dialog box.
2. Select the *default* update site from the drop-down menu (**https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml**).
3. Select the **Saxon 9.6 XSLT and XQuery Transformer** plugin and click **Next**.
4. Select the **I accept all terms of the end user license agreement** option and click **Finish**.
5. Restart the application.

Result: When you configure the transformation scenario, you will now have the option to choose the Saxon 9.6 transformer.

Scroll Function of my Notebook Trackpad is Not Working

Problem

I got a new notebook (Lenovo Thinkpad™ with Windows) and noticed that the scroll function of my trackpad is not working in Oxygen XML Editor.

Cause

It is most likely a problem with the Synaptics™ trackpads.

Solution

Try adding the following lines to the `C:\Program Files\Synaptics\SynTP\TP4table.dat` file (depending on your version of Oxygen XML Editor). For example:

```
*,*,oxygen20.1.exe,*,*,*,WheelStd,1,9
*,*,oxygenAuthor20.1.exe,*,*,*,WheelStd,1,9
```

```
*,*,oxygenDeveloper20.1.exe,*,*,*,WheelStd,1,9
*,*,syncroSVNClient.exe,*,*,*,WheelStd,1,9
*,*,diffDirs.exe,*,*,*,WheelStd,1,9
*,*,diffFiles.exe,*,*,*,WheelStd,1,9
```

Special Characters are Replaced with a Square

Problem

My file was created with another application and it contains special characters (such as é, ©, ®, etc.) but Oxygen XML Editor displays a square for these characters.

Solution

You must set a font that is able to render the special characters in the **Font** preferences *(on page 140)*. If it is a text file, you must also set the encoding used for non XML files *(on page 175)*. If you want to set a font that is installed on your computer but that font is not accessible in the **Font** preferences, this means the Java virtual machine is not able to load the system fonts (probably because it is not a True Type font). It is a problem of the Java virtual machine and a possible solution is to copy the font file in the `[JVM_DIR]/lib/fonts` folder. `[JVM_DIR]` is the value of the property *java.home* that is available in the **System properties** tab of the **About** dialog box that is opened from menu **Help > About**.

TocJS Transformation Does not Generate All Files for a Tree-Like TOC

Problem

The *TocJS* transformation of a *DITA map (on page 3419)* does not generate all the files needed to display the tree-like table of contents.

Solution

To get a complete set of output files, follow these steps:

1. Run the *XHTML* transformation on the same *DITA map*. Make sure the output gets generated in the same output folder as for the *TocJS* transformation.
2. Copy the content of the *`DITA-OT-DIR`*`/plugins/com.sophos.tocjs/basefiles` folder to the transformation output folder.
3. Copy the *`DITA-OT-DIR`*`/plugins/com.sophos.tocjs/sample/basefiles/frameset.html` file to the transformation output folder.
4. Edit `frameset.html` file.
5. Locate element `<frame name="contentwin" src="concepts/about.html">`.
6. Replace `"concepts/about.html"` with `"index.html"`.

Text on Buttons and Labels is Invisible for Linux Installer

Problem

After starting the Linux installer, the text on buttons and labels is invisible.

Cause

This seems to be a font issue between Oracle Java SE 8 (bundled with the installer) and Fedora/Gnome.

Solution

There are two possible workarounds:

- Run the installer with the default (non-native) Java L&F by using the `-Dinstall4j.nolaf=true` argument. For example:

  ```
  oxygen-64bit-openjdk.sh -Dinstall4j.nolaf=true
  ```

- Run the installer in console mode using the `-c` argument. For example:

  ```
  oxygen-64bit-openjdk.sh -c
  ```

Text Rendering Issues on macOS

Problem

On macOS, I sometimes encounter issues there text is not rendered properly. For example, when tags are displayed in **Author** mode, sometimes the tag icon is rendered over the top of text (hiding the text) and sometimes text flows outside of code blocks.

Cause

This is an uncommon error that cannot be fixed in current versions.

Solution

Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Editor > Edit modes > Author**, and deselect the **Fast text layout** option *(on page 184)*.

XML Document Takes a Long Time to Open

Problem

Oxygen XML Editor takes a long time to open an XML document.

Cause

It takes longer to open an XML document if the whole content of your document is on a single line or if the document size is very large.

Solution

If the content is on a single line, you can speed up loading by selecting the **Format and indent the document on open** option *(on page 212)* (in the **Format** preferences page).

If the document is very large (above 30 MB), make sure that the value of the **Optimize loading in the Text edit mode for files over** option *(on page 208)* (in the **Open** preferences page) is greater than the size of your document.

If that fails and you get an Out Of Memory error (**OutOfMemoryError**) you can increase the memory available to Oxygen XML Editor. *(on page 3033)*

XSLT Debugger Is Very Slow

Problem

When I run a transformation in the **XSLT Debugger** *perspective (on page 3422)*, it is very slow.

Solution

If the transformation produces HTML or XHTML output, you can disable rendering of output in the XHTML output view *(on page 265)* during the transformation process. To view the XHTML output result do one of the following:

- Run the transformation in the **Editor** *perspective (on page 3422)* and make sure the **Open in Browser/ System Application** option *(on page 1514)* is selected.
- Run the transformation in the **XSLT Debugger** *perspective (on page 3422)*, save the text output area to a file, and use a browser application for viewing it (for example, Firefox or Chrome).

22.

DITA Authoring

DITA is an XML standard, an architectural approach, and a writing methodology, developed by technical communicators for technical communicators. It provides a standardised architectural *framework (on page 3420)* for a common structure for content that promotes the consistent creation, sharing, and re-use of content.

Some of the benefits of using DITA include the following:

- **Flexibility** - DITA is a topic-based architecture and it offers flexibility in content organization.
- **Modularity** - DITA allows for content reuse that saves time and reduces the number of modifications.
- **Structured Authoring** - DITA offers a standardized, methodological approach that helps to reduce authoring time and improve consistency.
- **Single-Source Publishing** - DITA provides the ability to change content in one place and have the change propagate everywhere.
- **Multiple Output Formats** - DITA supports multiple types of output.
- **Inheritance** - The DITA inheritance model makes it easy to specialize topics or elements within topics and you only have to define how the element is different from its immediate ancestor.
- **Process Automation** - DITA offers various ways to automate processes, such as with index or glossary production, output delivery, validation, and more.
- **Specialization** - DITA allows you to define your own information types and semantic elements/attributes to suit the needs of your particular content model.
- **Multi-Lingual** - DITA is a translation-friendly structure that supports numerous languages and text encodings.
- **Conditional Profiling** - DITA supports conditional text processing and profiling to filter content in the publishing stage.

This chapter is designed to be a guide to help content authors who use DITA. It also presents the Oxygen XML Editor features that are specific to working with DITA documents and concepts.

DITA Resources

For more information and technical details about working with DITA, refer to the following resources:

- The DITA Specifications.
- The DITA Style Guide Best Practices for Authors.
- Various sample DITA topics and maps can be found in the `[OXYGEN_INSTALL_DIR]/samples/dita` folder.
- Webinar: **Getting Started with DITA Using Oxygen**
- Webinar: **DITA Project Management, Validation, and Translation in a Docs as Code Environment**

Related information

DITA Topics Document Type (Framework) *(on page 1373)*

DITA Map Document Type (Framework) *(on page 1397)*

Getting Started with DITA

The information in this topic is meant to be a very basic starting point for those who are just getting started using DITA in Oxygen XML Editor. Oxygen XML Editor makes it easy to create, edit, manage, and publish DITA content, but it requires at least some basic DITA knowledge. To truly get the most out of Oxygen XML Editor and all of its DITA-related features, you should explore resources in the online DITA community to acquire knowledge of its concepts and uses.

Understanding DITA Topics

It is important to understand the role that a DITA topic plays in a DITA project. A DITA topic is not associated with a single published document. It is a separate entity that can potentially be included in many different books, help systems, or websites. Therefore, when you write a DITA topic you are not writing a book, a help system, or a website. You are writing an individual piece of content. This affects how you approach the writing task and how Oxygen XML Editor works to support you as you write.

Most of your topics are actually related to other topics, and those relationships can affect how you write and handle things such as links and content reuse. Oxygen XML Editor helps you manage those relationships. Depending on how your topics are related, you can use the tools provided in Oxygen XML Editor, along with the features of DITA, in a variety of ways.

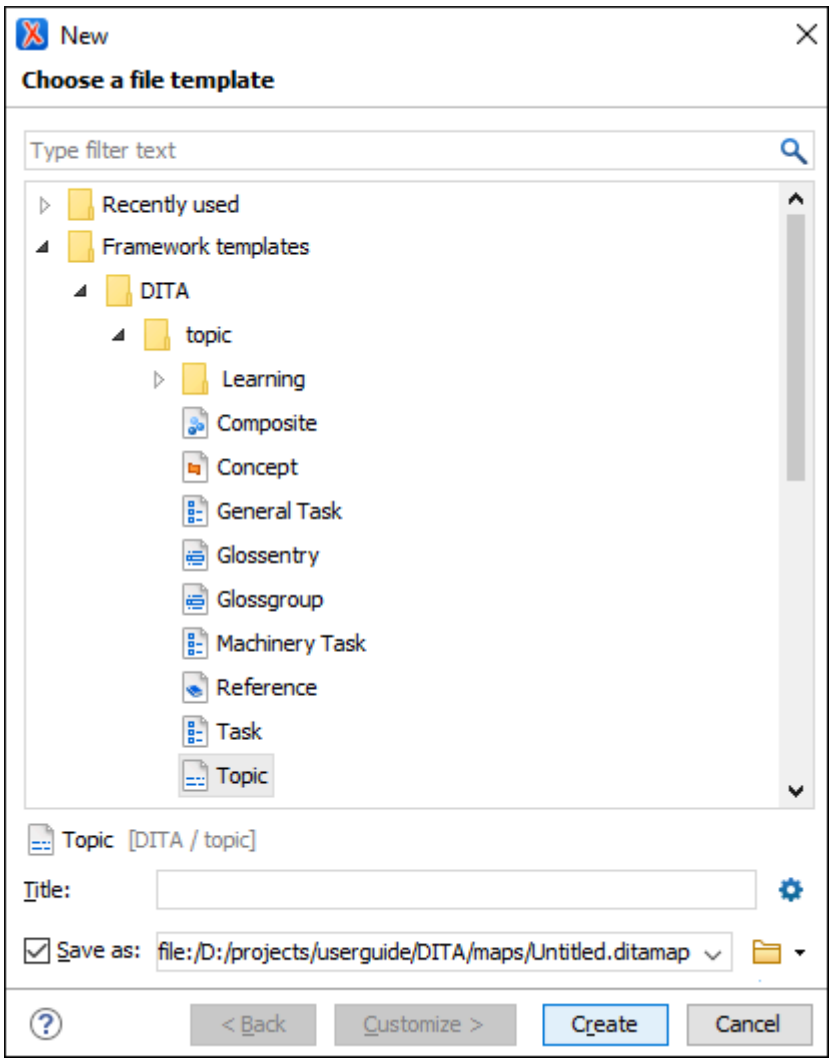
Creating a DITA Topic in Oxygen XML Editor

To create a DITA topic *(on page 3138)*:

1. Select **File >**  **New** or click the  **New** button on the toolbar.

   Step Result: The **New Document Wizard** *(on page 377)* is displayed:

Figure 758. New DITA Document Wizard



2. Go to **Framework templates > DITA > topic** and select the type of topic that you want to create.

> **Note:**
> If your organization has created DITA customizations, the appropriate template files may be in another location, and various types of topics may be provided for your use. Check with the person who manages your DITA system to see if you should be using templates from another directory.

3. Select a file path where it will be saved. You can also optionally specify a title.
4. Click **Create**.

Result: Your document is opened in the editor. Eventually, you will need to add a reference to it in your DITA map *(on page 3066)*.

Your DITA topic is an XML document, thus all the editing features that Oxygen XML Editor provides for editing XML documents *(on page 34)* also apply to DITA topics. Oxygen XML Editor also provides additional specific

DITA-related support for working with DITA topics *(on page 3136)*, their associated *DITA maps (on page 3071)*, and for creating DITA output *(on page 3263)*.

Role of Maps

The basic method that DITA uses to express the relationship between topics is through a *DITA map (on page 3419)*. Other relationships between topics, such as cross references, generally need to be made between topics in the same root map. DITA uses maps to determine which topics are part of any output that you create. While customized DITA solutions can use other mechanisms, generally DITA is not used as a way to publish individual topics. Output is created from a map and includes all the topics referenced by the map.

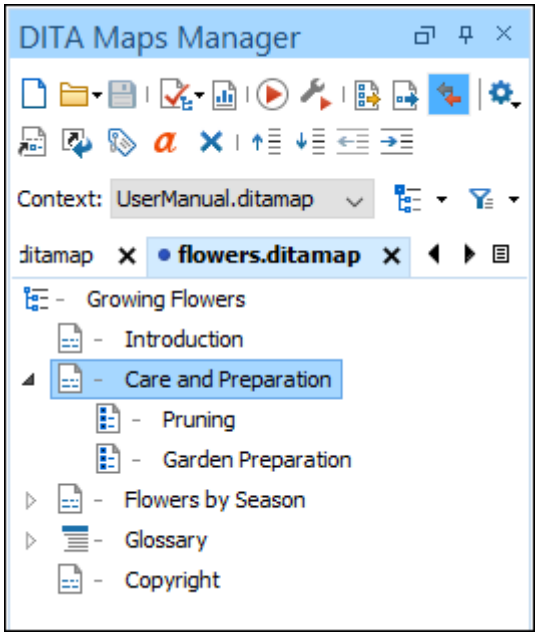
A publication is not always represented by a single map. For instance, if you are writing a book, you might use a submap to create each chapter and then organize the chapters in a main root map to create the book. This helps you to manage your content, offers the possibility of reusing submaps, and segregates content to support multiple people working on the same project.

Creating a Map in Oxygen XML Editor

To create a map *(on page 3090)*:

1. Select **File >** **New** or click the **New** button on the toolbar.
2. Go to **Framework templates > DITA Map > map** and select the type of map you want to create.
3. Choose whether you want to open the map in the **Editor** or in the **DITA Maps Manager** *(on page 3073)*. Usually, opening it in the **DITA Maps Manager** is the best choice. The **DITA Maps Manager** presents a view of the *DITA map* that is similar to a table of contents.

Figure 759. DITA Maps Manager View



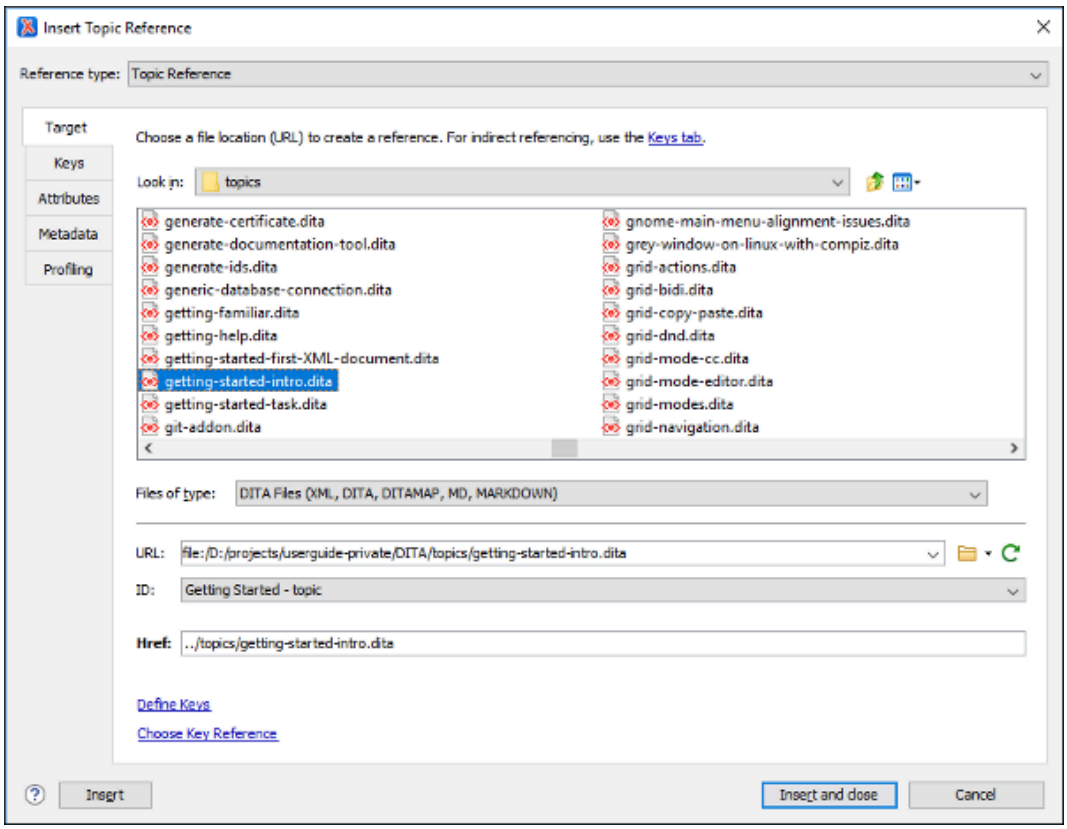
Adding Existing Topics to a Map in Oxygen XML Editor

There are several ways to add a topic reference to a map *(on page 3094)*. Perhaps the easiest method is to add a reference to a topic that is already open in the editor:

1. Open the DITA topic in the main editing window.
2. Right-click the *DITA map* in the **DITA Maps Manager** view *(on page 3073)* and choose **Reference to the currently edited file** from the **Append Child**, **Insert Before**, or **Insert After** submenu.

   Step Result: This opens the **Insert Reference** dialog box *(on page 3099)* with all of the required fields already filled in for you.

Figure 760. Insert Reference Dialog Box



3. You can fill in additional information in the various tabs in this dialog box or add it to the map later.
4. Select **Insert and close** to add a reference to your topic in the map.
5. Save the *DITA map*.

Adding New Topics to a Map in Oxygen XML Editor

As you add topics to your map, you may want to create a new topic as a child or sibling of another topic. This is usually done at the map level.

To add a new topic to a map *(on page 3094)*, follow these steps:

1. In the **DITA Maps Manager** *(on page 3073)*, right-click the node in the current map where you want to add the new topic.
2. Select one of the following actions:
   - **Append Child > New** - Select this action to insert the new topic as a child of the selected node. This action opens a **New** file dialog box *(on page 3139)* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
   - **Insert Before > New** - Select this action to insert the new topic as a sibling to the current node, before it. This action opens a **New** file dialog box *(on page 3139)* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
   - **Insert After > New** - Select this action to insert the new topic as a sibling to the current node, after it. This action opens a **New** file dialog box *(on page 3139)* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
   - **Duplicate** - Select this action to create a copy of the selected topic and insert it as a sibling. This action opens a dialog box that allows you to choose the file name and location for the newly created copy of the topic. After you have selected the name and path for your new topic, click **OK**.

     Note:
     The value of the root ID is generated taking the *Use the file name as the value of the root ID attribute* option from the **DITA > Topics** preferences page *(on page 282)* into account. When the option is deselected, a unique ID is generated.

   Step Result: The new topic is now referenced (as a `<topicref>`) in the *DITA map* at the location where you inserted it and the new topic is opened in the editor.
3. Save the *DITA map*.

You can also change the order and nesting of topics in the **DITA Maps Manager** view by doing either of the following:

- Select the topic to move while holding down the **Alt** key and use the arrow keys to move it around.
- Use the mouse to drag and drop the topic to the desired location.

The way your parent and child topics are organized in any particular output depends on both the configuration of those topics in the map and the rules of the output transformation that is applied to them. Do not assume that your topics must have the same organization for all output types. The map defines the organization of the topics, not the topics themselves. It is possible to create a variety of maps, each with different organization and configuration options to produce a variety of outputs.

Adding Submaps in Oxygen XML Editor

If you have a large set of information, such as a long book or extensive help system, a single map can become long and difficult to manage. To make it easier to manage, you can break up the content into smaller submaps *(on page 3091)*. A submap might represent a chapter of a book, a section of a user manual, or a page on a website. To build a publication out of these smaller maps, you must add them to a map that represents the overall publication.

To add a child map to the current map *(on page 3091)*:

1. Right-click the parent *DITA map* in the **DITA Maps Manager** view *(on page 3073)* and choose **Append child > Map reference**.

   Step Result: This opens the **Insert Reference** dialog box *(on page 3099)* with all of the required fields already filled in for you.
2. You can fill in additional information in the various tabs in this dialog box or add it to the map later.
3. Select **Insert and close** to add a reference to your submap in the main map.
4. Save the main *DITA map*.

Validating a Map in Oxygen XML Editor

Just as it is with your individual topics, it is important to validate your maps *(on page 3118)*. Oxygen XML Editor provides a validation function for *DITA maps* that does more than simply validating that the XML is well-formed. It also does the following:

- Validates all of the relationships defined in the maps.
- Validates all of the files that are included in the map.
- Validates all of the links that are expressed in the files.

Validating the map that describes your entire publication validates all the files that make up the publication and all of the relationships between them.

To validate a map:

1. Click the  **Validate and Check for Completeness** button in the **DITA Maps Manager** view *(on page 3073)*.

   Step Result: This opens the **DITA Map Completeness Check** dialog box *(on page 3119)*.
2. Select any of the various options you want to check.
3. Click **Check** to run the validation process.

Publishing Your Topics in Oxygen XML Editor

As noted previously, in DITA standards you usually do not publish output from an individual topic. Instead, you create published output *(on page 3263)* by running a DITA transformation on a map. This collects all the topics that are referenced in the map, organizes them, and produces output in a particular format. By

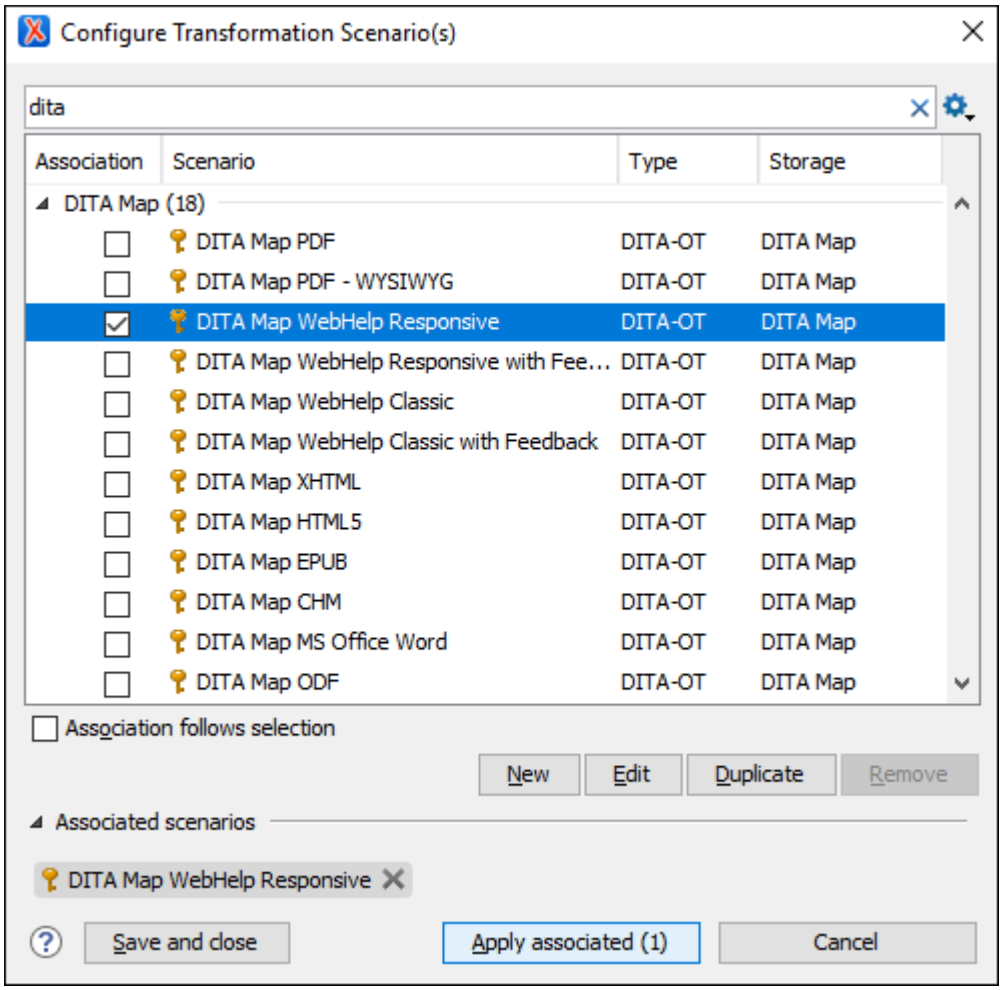
default, Oxygen XML Editor uses the transformations provided by the **DITA Open Toolkit** for publishing to various output formats (such as PDF, WebHelp or EPUB). Your organization may have created various custom transformations or modified the built-in **DITA Open Toolkit** transformations. In either case, Oxygen XML Editor manages them by using transformation scenarios.

To publish output for a map:

1. Click the **Configure Transformation Scenario(s)** button in the **DITA Maps Manager** view *(on page 3073)*.

   Step Result: This opens the **Configure Transformation Scenario(s)** dialog box *(on page 1600)*.

   Figure 761. Configure Transformation Scenarios Dialog Box



2. Select the appropriate transformation depending on the type of output you desire.
3. To change or view the configuration or storage options for a transformation scenario, select the transformation and click **Edit**.
4. Click **Apply associated**.

Result: Depending on the configuration of the transformation scenario, when the transformation is finished, your output may automatically be opened in the appropriate application.

DITA Projects

Once you have a basic understanding of DITA and how to work with DITA topics and maps, you probably want to create a DITA project to organize and manage your planned content/resources *(on page 409)*. Oxygen XML Editor includes a **Project** view *(on page 413)* that helps you organize your projects and offers a variety of helpful project-related features and makes it easy to share your projects with other members of your team.

Tip:
There are several sample project templates available for DITA users that can be used as a starting point or for inspiration. These sample project templates are found in the **Framework templates > DITA** folder in the **New Project** wizard: *(on page 410)*

- **Sample DITA Project** - This is a basic DITA project meant to help new users see how a DITA project is structured.
- **Startup DITA Project** - This is a startup DITA project that imposes a custom set of options (e.g. spell check settings and custom dictionaries), a custom DITA framework extension (e.g. custom new file templates. custom actions, custom CSS used for visual editing) and a folder structure for a DITA project according to best practices. Once created, the project contains a `Readme.html` file that explains all customizations and their benefits. If you plan to start your own DITA project using a version control system (such as Git), you can use this startup DITA project template to customize various aspects of DITA editing and share them with your team.

Working with Projects in DITA

Oxygen XML Editor provides the ability to organize your DITA resources in projects, the same as with other XML-related files. This helps you manage and organize your files and projects allow you to perform batch operations (such as validation and transformation) over multiple files or to use Main Files support to rename or move DITA resources *(on page 3368)* while updating the references to them. You can also share your project settings and transformation/validation scenarios *(on page 425)* with other users.

To learn how to create a new project from a template and how add resources and manage it, see Creating a New Project *(on page 409)*.

To help you get more familiar with how to use projects in DITA, there are two DITA-specific sample project templates available when using the **New Project** action (available, for example, from the **Project** menu):

- **DITA Project With Editing Customizations** - This sample DITA project imposes custom general settings and an editing behavior using a DITA framework extension. More details can be found in the project's `Readme.html` file.
- **Sample DITA Project** - This sample DITA project is a best practice example that shows how DITA content can be organized to provide a scalable and flexible project structure. More details can be found in the project's `Readme.html` file.

Using Projects to Group Documents *(on page 409)*

Working with DITA Maps

In the DITA standard architecture you create documents by collecting topics into maps.

DITA Maps

A *DITA map (on page 3419)* organizes a set of topics into a hierarchy. In most output formats, the structure of the map becomes the structure of the table of contents. Oxygen XML Editor provides support for creating *(on page 3090)* and managing *DITA maps (on page 3093)* through the **DITA Maps Manager** *(on page 3073)*. There are also specialized types of *DITA maps*, such as a *bookmap (on page 3417)*, which is intended for creating the structure of a book.

Submaps

You do not have to create an entire publication using a single map. It is generally good practice to break up a large publication into several smaller submaps *(on page 3091)* that are easier to manage. You can reuse submaps in multiple publications by including them in each of the main maps. The **DITA Maps Manager** *(on page 3073)* provides support for easily creating and managing submaps.

Opening a DITA Map

There are several ways to open a *DITA map* and you can choose to open it in the **DITA Maps Manager** *(on page 3073)* or in the XML Editor. Use any of the following methods to open a map:

- To open a submap in its own tab in the **DITA Maps Manager**, simply double-click it (or right-click it and select **Open**).
- To open a map in the XML editor from the **DITA Maps Manager**, right-click it and select **Open Map in Editor**.
- Drag a *DITA map* file from your system browser and drop it in the XML editor. This will open the map in the editor.
- If you open a file with the `.ditamap` or `.bookmap` extension (from the **Project** view *(on page 413)* or a system browser), a dialog box is opened that offers you the choice of opening it in the XML editor or in the **DITA Maps Manager**.

  Note:
  If you select the **Do not show the dialog again** option, it will always be opened in the method that you choose and you will not be asked in the future. However, you can reset this by selecting **Always ask** for the **When opening a map** option in the **DITA** preferences page *(on page 279)*.

- To open a map in the **DITA Maps Manager**, you can right-click a map file in the **Project** view *(on page 413)* and select **Open with > DITA Maps Manager**.
- If you have a *DITA map* file open in the XML editor, you can open it in the **DITA Maps Manager** by right-clicking the title tab and selecting **Open in DITA Maps Manager View**.

Chunking DITA Maps

By default, many output types place a single topic on each output page. In some cases you may want to output multiple topics as a single output page (also known as chunking) *(on page 3118)*. To support this, Oxygen XML Editor provides an **Edit Properties** dialog box *(on page 3109)* that allows you to easily configure the attributes of a topic to control how your table of contents and topics are rendered in the output.

Validating a Map

You should validate your maps *(on page 3118)* to make sure that the individual topics are valid and that the relationships between them are working. Oxygen XML Editor provides a validation function for *DITA maps* that performs a comprehensive validation of a map and its topics.

Resources

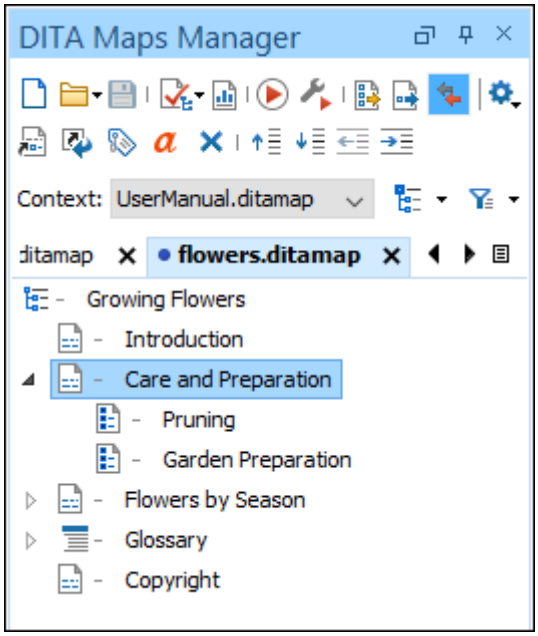
DITA Maps Manager

Oxygen XML Editor provides a view for managing and editing *DITA maps*. The **DITA Maps Manager** view presents a *DITA map* as a tree or table of contents. It allows you to navigate the topics and maps, make changes, and apply transformation scenarios to obtain various output formats. By default, it is located to the left of the main editor. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

The **DITA Maps Manager** includes a variety of useful actions to help you edit and organize the structure of your *DITA maps* and topics. The actions that are available and their functions depend on the type of nodes that are selected in the **DITA Maps Manager**. If you select multiple sibling nodes, the result of the actions will be applied to all the selected nodes. If you select multiple nodes that are not on the same hierarchical level, the actions will be applied to the parent node and the child nodes will inherit certain attributes from the parent node.

Figure 762. DITA Maps Manager View



An icon that represents its type of DITA resource is displayed on the left side of each node. For example, a DITA **Map** is displayed with the icon, a DITA **Topic** is displayed with , a DITA **Task** is displayed with , etc. Any node that has `processing-role="resource-only"` set in its properties is displayed with a gray dot in the bottom-right corner of the icon ( ).

The title of the DITA resource is also displayed for each node. The displayed title depends on how the referenced resource is configured within the DITA structure. For example, the title could be resolved as the text value inside the referenced topic's `<title>` element or the value of the `@navtitle` attribute specified within the DITA map. For non-DITA resources that are referenced in a DITA map, the file name of the resource is usually displayed for the title. However, it is possible to obtain the title from the referenced non-DITA documents by dynamically converting them using the process described in: Dynamic Word, Excel, OpenAPI, HTML, Markdown to DITA Conversion *(on page 3310)*. In this case, the document title obtained from the conversion process is displayed as the resource title in the **DITA Maps Manager**.

Opening Maps in the DITA Maps Manager

The **DITA Maps Manager** view supports opening multiple maps at the same time, with each one presented in its own tab. To open a *DITA map* in the **DITA Maps Manager**, use any of the following methods:

- To open a submap in its own tab, simply double-click it (or right-click it and select **Open**).
- If you open a file with a `.ditamap` or `.bookmap` extension (from the **Project** view *(on page 413)* or a system browser), a dialog box is opened that offers you the choice of opening it in the **DITA Maps Manager** or the XML editor.

  > **Note:**
  > If you select the **Do not show the dialog again** option, it will always be opened in the method that you choose and you will not be asked in the future. However, you can reset this by selecting the **Always ask** choice for the **When opening a map** option in the **DITA** preferences page *(on page 279)*.

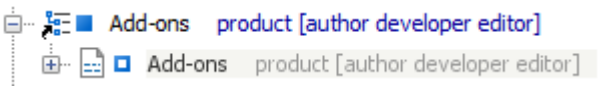
- Right-click a map file in the **Project** view *(on page 413)* and select **Open with > DITA Maps Manager**.
- If you have a *DITA map* file open in the XML editor, you can right-click the title tab and select **Open in DITA Maps Manager View**.

By default, when a map is opened in the **DITA Maps Manager**, its index is automatically refreshed. You can disable this feature by deselecting the **Refresh index when opening a map in DITA Maps Manager** option *(on page 307)* in the **Open/Find Resource** preferences page.

Submap Nodes

If your *root map (on page 3424)* (*main DITA map*) references other maps (submaps), they can be expanded and you can navigate their content in the **DITA Maps Manager**.

References within those submaps are not editable, by default, unless you open the submap separately in its own tab. If you want to be able to edit submaps when the main (root/parent) map is open in the **DITA Maps Manager**, go to **Options > Preferences > DITA > Maps** and select the **Allow referenced submaps to be edited** option *(on page 280)*. The references within submap nodes are shown with a gray background if they are not editable.



Moving Nodes in the DITA Maps Manager

You can move topics or nodes within the same map, or other maps, by dragging and dropping them into the desired position. You can arrange the nodes by dragging and dropping one or more nodes at a time. You can arrange multiple topics by dragging them while pressing the **Ctrl** or **Shift** key. Drop operations can be performed before, after, or as child of the targeted node.

Operations include:

Copy

Select the nodes you want to copy and start dragging them. Before dropping them in the appropriate place, press and hold the **Ctrl** key. The mouse pointer changes to a  symbol to indicate that a copy operation is being performed.

Move

Select the nodes you want to move and drag and drop them in the appropriate place.

Promote (Alt + LeftArrow) /Demote (Alt + RightArrow)

You can move nodes between child and parent nodes by using the **Promote** (**Alt + LeftArrow**) and **Demote** (**Alt + RightArrow**) operations.

DITA Maps Manager Toolbar

The toolbar includes the following actions (also available in the **DITA Maps** menu) and their availability depend on the nodes that are selected:

 **New DITA Map**

Opens the **New Document** wizard *(on page 377)* that you can use to create a new DITA map document.

 **Open Drop-down Menu**

You can use this drop-down menu to open new *DITA maps* or to reopen recently viewed maps. The drop-down menu contains the following:

- List of recently viewed *DITA maps* that can be selected to reopen them.
- **Clear history** - Clears the history list of the recently viewed *DITA maps*.
-  **Open** - Allows you to open the map in the **DITA Maps Manager** view *(on page 3073)*. You can also open a map by dragging it from the file system explorer and dropping it into the **DITA Maps Manager** view *(on page 3073)*.
-  **Open URL** - Displays the **Open URL** dialog box where you can specify a URL (defined by a protocol, host, resource path, and an optional port) or use the browsing actions in the  **Browse for remote file** drop-down menu.

 **Save (Ctrl + S (Meta + S on macOS))**

Saves the current *DITA map*.

 **Validation drop-down menu**

This drop-down menu contains options for validating the current map. The following options are available:

 **Validate and Check for Completeness**

Opens the **DITA Map Completeness Check** dialog box where you can configure options for checking the validity and integrity *(on page 3118)* of the map.

Validate

Validates the current map that is open in the **DITA Maps Manager** using the associated validation scenarios.

Configure Validation Scenario(s)

Use this option to configure validation scenarios and their associations *(on page 809)*.

Generate Metrics Report

Generate a report that contains statistics *(on page 3284)* about the entire DITA map in HTML format.

Apply Transformation Scenario(s)

Applies the DITA Map transformation scenario *(on page 1471)* that is associated with the current map.

Configure Transformation Scenario(s)

Opens the **Configure Transformation Scenarios(s)** dialog box *(on page 1600)* where you can edit or create transformation scenarios or associate a DITA Map transformation scenario *(on page 1530)* with the current map.

Open Map in Editor with Resolved Topics

Opens the *DITA map* in the main editor area with content from all topic references expanded in-place. Referenced content is presented as read-only by default. To edit it, you must use the **Edit Reference** contextual menu action to open the source topic that contains the referenced content.

If you want to edit the referenced topics directly without having to open the source document, go to **Options > Preferences > Editor > Edit Modes > Author** and select the **Allow referenced content to be edited** option *(on page 186)*. Since a single topic may be referenced in multiple places in the DITA map, be careful not to make conflicting changes to that topic.

Tip:
If you want to print the expanded content, you should consider changing selecting **+ Print ready** from the **Styles** drop-down menu on the toolbar.

Open Map in Editor

For complex operations that cannot be performed in the simplified **DITA Maps Manager** view (for instance, editing a relationship table) you can open the map in the main editing area.

Note:
You can also use this action to open referenced *DITA maps* in the **Editor**.

Link with Editor

Toggles the synchronization between the file path of the current editor and the selected topic reference in the **DITA Maps Manager** view. If enabled, it results in the following types of synchronizations:

- If you select a topic tab in the main editing area and it is referenced in the map currently opened in the **DITA Maps Manager**, the reference to that topic is selected in the **DITA Maps Manager**.
- If you have a map opened in both the **DITA Maps Manager** and the main editor, selecting the map tab in the main editing area opens that map in the **DITA Maps Manager**.
- If you have a map opened in both the **DITA Maps Manager** and the main editor (**Author** mode), selecting one or more *topicrefs* in the **DITA Maps Manager** will also select the same *topicrefs* in the main editor.
- If you have a map opened in both the **DITA Maps Manager** and the main editor (**Author** mode), selecting one or more *topicrefs* in the main editor will also select the same *topicrefs* in the **DITA Maps Manager**.

Settings

Show extended toolbar

Toggles whether or not the extended toolbar will be displayed in the **DITA Maps Manager** toolbar.

Show context toolbar

Toggles whether or not the **Context** option *(on page 3077)* will be displayed in the **DITA Maps Manager** toolbar.

Show topic titles

Toggles how topics are presented in the **DITA Maps Manager**. If selected, the title of each topic is shown. Otherwise, the file path (value of the `@href` attribute) for each topic is shown.

Show key reference values

Toggles how key references are presented in the **DITA Maps Manager**. If selected, the value of the `@keyref` attribute for each key reference is shown.

Context Root Map Drop-down menu

The drop-down menu displayed after **Context** can be used to specify the *DITA root map (on page 3424)*) that Oxygen XML Editor uses to define a hierarchical structure of submaps and to establish a *key space (on page 3421)* that defines the keys that are propagated throughout the entire map structure. For more information, see Selecting a Root Map *(on page 3090)*.

Choose context root map browsing/search menu

You can use this drop-down menu to browse or search for *root maps* with the following choices:

- **Browse for local file** - Opens a local file browser dialog box, allowing you to select a local *root map*.
- **Browse for remote file** - Displays the **Open URL** dialog box *(on page 397)* that allows you to select a remotely stored *root map*.
- **Browse for archived file** - Displays the **Archive Browser** *(on page 2126)* that allows you to browse the content of an archive and choose a *root map*.
- **Browse Data Source Explorer** - Opens the **Data Source Explorer** *(on page 2133)* that allows you to browse the data sources defined in the Data Sources preferences page *(on page 285)*.

> **Tip:**
> You can open the **Data Sources** preferences page by using the **Configure Database Sources** shortcut from the **Open URL** dialog box.

- **Search for file** - Displays the **Find Resource** dialog box *(on page 436)* to search for a *root map*.
- **Choose context from main files** - Allows you to choose a context root map from the DITA maps and the DITA-OT project files that are set in the Main Files *(on page 3368)* folder.

Profiling/Conditional Text Drop-down Menu

You can use this drop-down menu to select and apply a defined profiling condition set *(on page 3328)* to filter the content based on that condition set. The drop-down menu also contains the following other options:

- **Show Profiling Colors and Styles** - Select this option to turn on conditional styling. To configure the colors and styles open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Editor > Edit modes > Author > Profiling/Conditional Text > Colors and Styles**.
- **Show Profiling Attributes** - Select this option to display the values of the profiling attributes at the end of the titles of topic references. When selected, the values of the profiling attributes are displayed in both the **DITA Maps Manager** view and in the **Author** view.
- **Show Excluded Content** - Controls if the content filtered out by a particular condition set is hidden or grayed-out in the editor area and in the **Outline** *(on page 549)* and **DITA Maps Manager** views. When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

- **Profiling Settings** - Opens the preferences page for adding and editing the profiling conditions that you can apply in the **DITA Maps Manager** view and the **Author** mode editing pane. When a profiling condition set *(on page 686)* is applied, the keys that are defined in the *DITA map* are gathered by filtering out the excluded content.

The following additional actions are displayed in the toolbar when the **Show extended toolbar** option is selected in the **Settings** menu:

Insert Topic Reference

Opens the **Insert Reference** dialog box *(on page 3099)* that allows you to insert references to targets such as topics, maps, topic sets, or key definitions.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced documents. This action is useful when the referenced documents are modified externally. When they are modified and saved from Oxygen XML Editor, the *DITA map* is updated automatically.

Edit Properties

Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see Edit Properties Dialog Box *(on page 3109)*.

Edit Attributes

Opens a small in-place editor that allows you to edit the attributes of a selected node. You can find more details about this action in the Attributes View in Author Mode *(on page 638)* topic.

Delete

Deletes the selected node.

Move Up

Moves the selected node up within the *DITA map* tree.

Move Down

Moves the selected node down within the *DITA map* tree.

Promote(Alt + LeftArrow)

Moves the selected node up one level to the level of its parent node.

Demote(Alt + RightArrow)

Moves the selected node down one level to the level of its child nodes.

Contextual Menu of the DITA Maps Manager

Root Map

The following actions can be invoked from the contextual menu on the *root map (on page 3424)* of an opened *DITA map* (many of them are also available in the**DITA Maps** menu):

Open Map in Editor

For complex operations that cannot be performed in the simplified **DITA Maps Manager** view (for instance, editing a relationship table) you can open the map in the main editing area.

Open Map in Editor with Resolved Topics

Opens the *DITA map* in the main editor area with content from all topic references, expanded in-place. Content from the referenced topics is presented as read-only and you have to use the contextual menu action **Edit Reference** to open the topic for editing.

Export DITA Map

Opens a dialog box that allows you to choose a destination for exporting the *DITA map*. It also includes an **Export as Zip archive** option that allows you to package the *DITA map* as a zip archive. The result will contain all directly and indirectly referenced topics from the DITA Map.

Find Unreferenced Resources

Allows you to search for orphaned resources that are not referenced in the *DITA maps*.

Add to Review Task

This action can be used to add the selected documents to a task in the **Content Fusion Tasks Manager** view. **Oxygen Content Fusion** is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on *(on page 2651)*. To fully take advantage of all of the benefits and features of **Content Fusion**, your organization will need an **Oxygen Content Fusion Enterprise Server**. For more information, see the **Oxygen Content Fusion** website.

Show Feedback Comments Manager

Opens the **Feedback Comments Manager** view. This view is for those who use **Oxygen Feedback** to provide a commenting component in WebHelp output. This view makes it possible to see all the comments added by users in WebHelp output directly in Oxygen XML Editor.

Edit Properties

Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see Edit Properties Dialog Box *(on page 3109)*.

Fast Create Topics

Opens the **Fast Create Topics** dialog box *(on page 3141)* that allows you to quickly create multiple skeleton topics at once and you can specify their hierarchical structure within the *DITA map (on page 3419)*.

Append Child submenu

Container sub-menu for a number of actions that create a map node as a child of the currently selected node:

- **New** - Opens a dialog box that allows you to configure some options for inserting a new topic *(on page 3138)*.
-  **Reference** - Inserts a reference to a topic file. You can find more details about this action in the Inserting References *(on page 3099)* topic.
- **Reference to the currently edited file** - Inserts a reference to the currently edited file. You can find more details about this action in the Inserting References *(on page 3099)* topic.
- **Key Reference** - Opens an **Insert Key Definition** dialog box that allows you to insert a *targeted key definition (on page 3109)* (for example, to target a resource such as an image or external link).
- **Key Reference with Keyword** - Opens an **Insert Key Definition** dialog box that allows you to define a key and a value inside a *keyword (on page 3108)*.
- A set of actions that open the **Insert Reference** dialog box *(on page 3099)* that allows you to insert various reference specializations (such as **Anchor Reference**, **Glossary Reference**, **Map Reference**, **Navigation Reference**, **Topic Group**, **Topic Head**, **Topic Reference**, **Topic Set**, **Topic Set Reference**).

 **Search References**

Searches all references to the current topic in the entire *DITA map (on page 3419)*. It also reports references that are defined as related links in relationship tables. If you have enabled Main Files support *(on page 3368)*, it also searches for references in the DITA maps added to the Main Files folder.

Refactoring submenu

The following actions are available from this submenu when invoked from a root map:

Rename resource

Allows you to change the name of a resource linked in the edited *DITA map (on page 3096)* and you have the option of updating all the references to the renamed DITA resource. If you have enabled Main Files support *(on page 3368)*, it also searches for references in the DITA maps added to the Main Files folder and it provides the option of updating all the references even for non-DITA resources.

Move resource

Allows you to change the location on disk of a resource linked in the edited *DITA map (on page 3096)* and you have the option of updating all the references to the moved DITA resources. If you have enabled Main Files support *(on page 3368)*, it also searches for references in the DITA maps added to the Main Files folder and it provides the option of updating all the references even for non-DITA resources.

Rename Key

Use this operation to rename a key. It also updates all references to it. Note that it does not work on DITA 1.3 key scopes.

Convert to Concept

Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept).

Convert to General Task

Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). A DITA *General Task* is a less restrictive alternative to the *Strict Task* information type.

Convert to Reference

Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference).

Convert to Task

Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task).

Convert to Topic

Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic).

Convert to Troubleshooting

Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting).

Generate IDs

Use this operation to automatically generate unique IDs for elements.

Other XML Refactoring Actions

For your convenience, the last 5 XML Refactoring tool operations *(on page 852)* that were finished or previewed will also appear in this submenu.

XML Refactoring

Opens the XML Refactoring tool wizard *(on page 852)* that presents refactoring operations to assist you with managing the structure of your XML documents.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace content across multiple files.

Check Spelling in Files

Allows you to spell check multiple files *(on page 469)*.

Paste

Allows you to paste content from the clipboard into the *DITA map*.

Paste Before

Pastes the content of the clipboard (only if it is a part of the *DITA map*) before the currently selected *DITA map* node.

Paste After

Pastes the content of the clipboard (only if it is a part of the *DITA map*) after the currently selected *DITA map* node.

Expand All

Allows you to expand the entire *DITA map* structure.

Collapse All

Allows you to collapse the entire *DITA map* structure.

Editable Child Nodes

The following actions are available when the contextual menu is invoked on an editable child node of a *DITA map*:

Note:
If multiple nodes are selected, the availability of the actions depends on the nodes that are selected.

Note:
Topic references inside submaps are not editable by default. If you want to be able to edit submaps when the main (root/parent) map is open in the **DITA Maps Manager**, go to **Options > Preferences > DITA > Maps** and select the **Allow referenced submaps to be edited** option *(on page 280)*.

Open

Opens the selected resource in the editor.

Add to Review Task

This action can be used to add the selected documents to a task in the **Content Fusion Tasks Manager** view. **Oxygen Content Fusion** is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on *(on page 2651)*. To fully take advantage of all of the benefits and features of **Content Fusion**, your organization will need an **Oxygen Content Fusion Enterprise Server**. For more information, see the **Oxygen Content Fusion** website.

Edit Properties

Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see Edit Properties Dialog Box *(on page 3109)*.

Fast Create Topics

Opens the **Fast Create Topics** dialog box *(on page 3141)* that allows you to quickly create multiple skeleton topics at once and you can specify their hierarchical structure within the *DITA map (on page 3419)*.

Append Child submenu

Container sub-menu for a number of actions that create a map node as a child of the currently selected node:

- **New** - Opens a dialog box that allows you to configure some options for inserting a new topic *(on page 3138)*.
- **Reference** - Inserts a reference to a topic file. You can find more details about this action in the Inserting References *(on page 3099)* topic.
- **Reference to the currently edited file** - Inserts a reference to the currently edited file. You can find more details about this action in the Inserting References *(on page 3099)* topic.
- **Key Reference** - Opens an **Insert Key Definition** dialog box that allows you to insert a *targeted key definition (on page 3109)* (for example, to target a resource such as an image or external link).
- **Key Reference with Keyword** - Opens an **Insert Key Definition** dialog box that allows you to define a key and a value inside a *keyword (on page 3108)*.
- A set of actions that open the **Insert Reference** dialog box *(on page 3099)* that allows you to insert various reference specializations (such as **Anchor Reference**, **Glossary Reference**, **Map Reference**, **Navigation Reference**, **Topic Group**, **Topic Head**, **Topic Reference**, **Topic Set**, **Topic Set Reference**).

Insert Before submenu

Container sub-menus for a number of actions that create a map node as a sibling of the currently selected node, above the current node in the map:

- **New** - Opens a dialog box that allows you to configure some options for inserting a new topic *(on page 3138)*.
- **Reference** - Inserts a reference to a topic file. You can find more details about this action in the Inserting References *(on page 3099)* topic.
- **Reference to the currently edited file** - Inserts a reference to the currently edited file. You can find more details about this action in the Inserting References *(on page 3099)* topic.
- **Key Reference** - Opens an **Insert Key Definition** dialog box that allows you to insert a *targeted key definition (on page 3109)* (for example, to target a resource such as an image or external link).
- **Key Reference with Keyword** - Opens an **Insert Key Definition** dialog box that allows you to define a key and a value inside a *keyword (on page 3108)*.
- A set of actions that open the **Insert Reference** dialog box *(on page 3099)* that allows you to insert various reference specializations (such as **Anchor Reference**, **Glossary Reference**, **Map Reference**, **Navigation Reference**, **Topic Group**, **Topic Head**, **Topic Reference**, **Topic Set**, **Topic Set Reference**).

Insert After submenu

Container sub-menus for a number of actions that create a map node as a sibling of the currently selected node, below the current node in the map:

- **New** - Opens a dialog box that allows you to configure some options for inserting a new topic *(on page 3138)*.
- **Reference** - Inserts a reference to a topic file. You can find more details about this action in the Inserting References *(on page 3099)* topic.
- **Reference to the currently edited file** - Inserts a reference to the currently edited file. You can find more details about this action in the Inserting References *(on page 3099)* topic.
- **Key Reference** - Opens an **Insert Key Definition** dialog box that allows you to insert a *targeted key definition (on page 3109)* (for example, to target a resource such as an image or external link).
- **Key Reference with Keyword** - Opens an **Insert Key Definition** dialog box that allows you to define a key and a value inside a *keyword (on page 3108)*.
- A set of actions that open the **Insert Reference** dialog box *(on page 3099)* that allows you to insert various reference specializations (such as **Anchor Reference**, **Glossary Reference**, **Map Reference**, **Navigation Reference**, **Topic Group**, **Topic Head**, **Topic Reference**, **Topic Set**, **Topic Set Reference**).

Search References

Searches all references to the current topic in the entire *DITA map (on page 3419)*. It also reports references that are defined as related links in relationship tables. If you have enabled Main Files support *(on page 3368)*, it also searches for references in the DITA maps added to the Main Files folder.

Refactoring submenu

The following actions are available from this submenu:

Convert Markdown to DITA Topic (Available for Markdown documents)

Opens a dialog box that allows you to configure options for converting the Markdown document into a DITA topic *(on page 3204)*.

Rename resource

Allows you to change the name of a resource linked in the edited *DITA map (on page 3096)* and you have the option of updating all the references to the renamed DITA resource. If you have enabled Main Files support *(on page 3368)*, it also searches for references in the DITA maps added to the Main Files folder and it provides the option of updating all the references even for non-DITA resources.

Move resource

Allows you to change the location on disk of a resource linked in the edited *DITA map (on page 3096)* and you have the option of updating all the references to the moved DITA resources. If you have enabled Main Files support *(on page 3368)*, it also searches for references in the DITA maps added to the Main Files folder and it provides the option of updating all the references even for non-DITA resources.

Extract to New DITA Map

Use this operation to extract editable topics into a new *DITA map*. The operation will open a map creation dialog box where you can select the type of map and configure the title or file name. Click **Create** to complete the operation and a new DITA map will be inserted at the location where the action was invoked with the selected topic references moved into the new map.

Rename Key

Use this operation to rename a key. It also updates all references to it. Note that it does not work on DITA 1.3 key scopes.

Convert Nested Topics to New Topics (Available from the contextual menu of editable maps/nodes in the DITA Maps Manager *(on page 3073)*)

Use this operation on topics that contain nested `<topic>` elements to convert each nested topic to a new topic. Also, the new topics are added in the **DITA Maps Manager** as the first child topics of the original topic.

Convert Sections to New Topics (Available from the contextual menu of editable maps/nodes in the DITA Maps Manager *(on page 3073)*)

Use this operation on topics that contain multiple sections to convert each section to a new topic. Also, the new topics are added in the **DITA Maps Manager** as the first child topics of the original topic.

Note:
As long as the DITA topic is of the type *topic*, *concept*, or *reference*, the new topics that will be created from the inner sections will retain the same topic type as the original topic.

Convert to Concept

Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept).

Convert to General Task

Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). A DITA *General Task* is a less restrictive alternative to the *Strict Task* information type.

Convert to Reference

Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference).

Convert to Task

Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task).

Convert to Topic

Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic).

Convert to Troubleshooting

Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting).

Generate IDs

Use this operation to automatically generate unique IDs for elements.

Other XML Refactoring Actions

For your convenience, the last 5 XML Refactoring tool operations *(on page 852)* that were finished or previewed will also appear in this submenu.

XML Refactoring

Opens the XML Refactoring tool wizard *(on page 852)* that presents refactoring operations to assist you with managing the structure of your XML documents.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 446)* that allows you to find and replace content across multiple files.

Check Spelling in Files

Allows you to spell check multiple files *(on page 469)*.

Cut

Deletes the currently selected node and copies it to the clipboard.

Copy

Copies the currently selected node to the clipboard.

Paste

Allows you to paste content from the clipboard into the *DITA map*.

Paste Before

Pastes the content of the clipboard (only if it is a part of the *DITA map*) before the currently selected *DITA map* node.

Paste After

Pastes the content of the clipboard (only if it is a part of the *DITA map*) after the currently selected *DITA map* node.

Delete

Deletes the currently selected node from the *DITA map*.

Remove from Disk

This action can be used to remove the selected resource(s) from disk. Selecting this action will open a confirmation dialog box where you can also choose to remove the descendants by selecting the **Also remove all descendants** option. If you proceed, a search for references is triggered. If multiple references are detected for any of the selected resources, you will have the option to review them since this would lead to broken links. If you have enabled Main Files support *(on page 3368)*, it also searches for references in the DITA maps added to the Main Files folder.

Organize

Allows you to organize the *DITA map* with the several submenu actions:

- **Move Up** - Moves the selected node up within the *DITA map* tree.
- **Move Down** - Moves the selected node down within the *DITA map* tree.
- **Promote**(**Alt + LeftArrow**) - Moves the selected node up one level to the level of its parent node.
- **Demote**(**Alt + RightArrow**) - Moves the selected node down one level to the level of its child nodes.

Expand All

Allows you to expand the entire *DITA map* structure.

Collapse All

Allows you to collapse the entire *DITA map* structure.

Other Nodes

The following additional actions are available when the contextual menu is invoked from other nodes, such as a *submap* node or a relationship table:

Open Map in Editor (available when invoking on a submap)

Opens the currently selected *DITA map* in the editor.

Open parent DITA map (available when invoking on a read-only topic reference or a submap reference)

Opens the parent *DITA map* of the currently selected reference in the **DITA Maps Manager**.

Edit Attributes (only available for relationship table nodes)

Opens a small in-place editor that allows you to edit the attributes of a selected node. You can find more details about this action in the Attributes View in Author Mode *(on page 638)* topic.

Edit Profiling Attributes (only available for relationship table nodes)

Allows you to change the profiling attributes *(on page 680)* defined on the selected node.

Creating a Map

To create a *DITA map (on page 3419)*, *subject scheme map (on page 3424)*, *bookmap (on page 3417)*, or other types of *DITA maps*, follow these steps:

1. Use the **New Document** wizard *(on page 377)* to start creating your map.

   Tip:
   If you want the *map* to be a submap, you can create it the same way by right-clicking the place in the current map where you want to add it (in the **DITA Maps Manager** *(on page 3073)*) and selecting **New** from the **Append Child**, **Insert Before**, or **Insert After** submenu.

2. Select one of the **DITA Map** templates from the **Framework templates** folder.
3. Click the **Create** button.
4. Select whether you want to open the map in the **DITA Maps Manager** *(on page 3073)* or the **Editor**.
5. Save the map using the **Save** button on the toolbar of the **DITA Maps Manager** view *(on page 3073)*.

Managing DITA Maps *(on page 3093)*

Selecting a Root Map

Oxygen XML Editor allows you to select a *root map (on page 3424)* (a main *DITA map (on page 3419)*) that defines a hierarchical structure of submaps and establishes a *key space (on page 3421)* that defines the keys used in all the other *DITA maps* and topics in the project. Specifying the correct *root map* helps to prevent validation problems when you work with *keyrefs* and also acts as the foundation for content completion. All the *keys* that are defined in a *root map* are available in the submaps that are contained within the *root map*.

There are several ways to select or change the *root map*:

- The easiest method is to use the **Context** drop-down menu *(on page 3077)* on the **DITA Maps Manager** *(on page 3073)* toolbar to select the appropriate *context root map* that Oxygen XML Editor uses to define a hierarchical structure of submaps and to establish a *key space (on page 3421)* that defines the keys that are propagated throughout the entire map structure.
- You can use the **Choose context root map** drop-down on the **DITA Maps Manager** *(on page 3073)* toolbar to browse or search for *root maps* with the following choices:

- **Browse for local file** - Opens a local file browser dialog box, allowing you to select a local *root map*.
- **Browse for remote file** - Displays the **Open URL** dialog box *(on page 397)* that allows you to select a remotely stored *root map*.
- **Browse for archived file** - Displays the **Archive Browser** *(on page 2126)* that allows you to browse the content of an archive and choose a *root map*.
- **Browse Data Source Explorer** - Opens the **Data Source Explorer** *(on page 2133)* that allows you to browse the data sources defined in the Data Sources preferences page *(on page 285)*.

  > **Tip:**
  > You can open the **Data Sources** preferences page by using the **Configure Database Sources** shortcut from the **Open URL** dialog box.

- **Search for file** - Displays the **Find Resource** dialog box *(on page 436)* to search for a *root map*.
- **Choose context from main files** - Allows you to choose a context root map from the DITA maps and the DITA-OT project files that are set in the Main Files *(on page 3368)* folder.

- If you insert a *key reference* using the **Cross Reference** action from the **Link** drop-down menu (from the toolbar or **Link** submenu of the contextual menu) and keys are not gathered from the expected *DITA map*, you can change the *root map* by using the **Change Root Map** link in the **Choose Key** dialog box that is opened when you click the **Choose Key Reference** button.
- If you insert a *content key reference* or *key reference* using the **Reuse Content** action (from the toolbar, **DITA** menu, or **Reuse** submenu of the contextual menu) and keys are not gathered from the expected *DITA map*, you can change the *root map* by using the **Change Root Map** link in the **Choose Key** dialog box that is opened when you click the **Choose Key Reference** button.

Creating DITA Submaps

You can break up a large *DITA map (on page 3419)* into more manageable pieces by creating submaps. A submap is simply a *DITA map* that is included by another *DITA map*. There is no separate markup for a submap.

For example, if you are creating a book, you might use one submap for each chapter of the book. If you are reusing a set of topics in multiple publications, you might collect them into a map and reuse the map as a submap in multiple other maps, rather than referencing the topics individually from the new maps.

You add a submap to a map the same way that you would add a new topic or insert an existing topic into a map *(on page 3094)*, except you choose a map rather than a topic to create or add. When adding a submap to a map make sure that you use a `<mapref>` element or a `<topicref>` element with the `@format` attribute set to `ditamap`. In most cases, Oxygen XML Editor takes care of this for you.

Adding a Submap to a Map

To add a submap to a map:

1. Right-click the place in the current map where you want to add the new submap.
2. To insert the submap as a child of the selected node, select **Append Child > New**. To insert the submap as a sibling to the current node, select **Insert After > New** or **Insert Before > New**.

   Step Result: This opens a **New** DITA file dialog box *(on page 3138)* that allows you to select the type of document and assists you with naming it.
3. Select the type of map in one of the folders inside the **DITA Map** folder and give it a name (the file should have a `.ditamap` file extension).
4. Click **Create** to insert the submap.

You can manage and move submaps the same as you would with topics. They can also be expanded and you can navigate their content in the **DITA Maps Manager** when the root (main) DITA map is open, but the references within those submaps are not editable, by default, unless you open the submap separately in its own tab.

Tip:
If you want to be able to edit submaps when the main (root/parent) map is open in the **DITA Maps Manager**, go to **Options > Preferences > DITA > Maps** and select the **Allow referenced submaps to be edited** option *(on page 280)*.

Managing DITA Maps *(on page 3093)*

Creating a Bookmap in DITA

If you want to create a traditional book in DITA, you can use a *bookmap (on page 3417)* to organize your topics into a book. A DITA *bookmap* is a specialized type of map, intended for creating output that is structured like a book. A *bookmap* allows you to add book-specific elements such as `<frontmatter>`, `<part>`, `<chapter>`, `<appendix>`, and `<backmatter>` to the map. How these book-specific elements are processed for publication is up to the processing script for each media. See the DITA documentation for details.

You can find additional support for creating books in DITA in the DITA for Publishers plugin, which is included with Oxygen XML Editor.

To create a book in DITA using a *bookmap*, follow these steps:

1. Create a new *bookmap (on page 3092)* (**File > New > Framework templates > DITA Map > map > Bookmap**). If you want the *bookmap* to be a submap, you can create it the same way by right-clicking the place in the current map where you want to add it (in the **DITA Maps Manager** *(on page 3073)*) and selecting **New** from the **Append Child**, **Insert Before**, or **Insert After** submenus.

2. Create the structure of your book by adding the appropriate book sections and defining containers for chapters and any appendices. To add sections to a *bookmap*, or children to a section, right-click the *bookmap* or section icon and choose any of the reference actions in the **Append child** menu. The selections offered in the menu will adjust depending on the element they are applied to. Consult the DITA documentation to fully understand the structure of a DITA *bookmap* and where to create each element.
3. Create special elements such as an index *(on page 3116)* and table of contents *(on page 3115)*. The index and table of contents will be generated by the build process, based on the content of the map and the topics it points to.
4. Add topics *(on page 3094)* to your chapters to add content to your book. You may find it easier to manage if you use submaps *(on page 3091)* to create the content of your chapters. This keeps your *bookmap* from becoming long and difficult to manage.

Managing DITA Maps

This section includes various topics that describe how you can manage *DITA maps* and resources. You may want to manage your *DITA maps (on page 3419)* in a variety of ways, including:

- Change the order and nesting of topics in a map.
- Add topics to a map.
- Insert various types of references in a map.
- Find, move, or rename resources in a map.
- Change other properties of the items in a map.
- Use the Edit Properties dialog box to manage attributes, keys, metadata, or add profiling to any section of a map.

Resources

For more information about the **DITA Maps Manager** view and many of its features, watch our video demonstration:

https://www.youtube.com/embed/ozFZz6YZMCY

Change the Order of Topics in DITA Maps

You can change the order and nesting of the topics in a map in several ways:

- By dragging and dropping topics within the **DITA Maps Manager** *(on page 3073)*.
- By highlighting a topic in the **DITA Maps Manager** *(on page 3073)*, holding down the **Alt** key, and pressing the arrow keys.
- By showing the extended **DITA Maps Manager** *(on page 3073)* toolbar (click the **Settings** icon on the **DITA Maps Manager** *(on page 3073)* toolbar and select the extended toolbar) and then using the node moving buttons () on the toolbar to move topics around in the map.

To understand how to organize topics in a *DITA map* using the **DITA Maps Manager** *(on page 3073)*, you can examine and experiment with the sample map called `flowers.ditamap`, located in the *`[OXYGEN_INSTALL_DIR]`*`/samples/dita` folder.

Adding Topics to a DITA Map

When you are working in DITA, there are several approaches that you can use to create topics and maps. You can start by first creating topics and then assembling your finished topics into one or more documents by creating one or more maps, or you can start by creating a map and then adding new topics to it as you work.

The topics-first approach is generally more appropriate if you intend to do a lot of content reuse, as it encourages you to think of each topic as an independent unit that can be combined with other topics in various ways. The map-first approach will be more familiar to you if you are used to creating books or manuals as a whole. Oxygen XML Editor supports both approaches.

A *DITA map (on page 3419)* organizes content hierarchically, so you can add a topic as a child of the map root element or as a child or sibling of any item already in the map. Therefore, the first step to adding a topic to a map is always to choose the place it will be inserted into the map.

Adding Existing Topics to a Map

At the XML-level, a topic is added to a map by adding a reference to the map that points to the topic. There are a variety of reference types that you can use. The default type is the `<topicref>` element. See the DITA documentation for the full range of reference elements and their uses. Oxygen XML Editor provides several tools for inserting reference elements into a map:

Using the Insert Reference Dialog Box

The **Insert Reference** dialog box *(on page 3099)* allows you to create various reference types and configure the most commonly used attributes. You can open the **Insert Reference** dialog box with any of the following methods:

- Right-click an item in the current map where you want to add the reference, select **Append Child**, **Insert Before**, or **Insert After** and select the type of reference to enter.
- If the topic you want to add is currently open in the editor, you can right-click an item in the current map where you want to add the reference and select **Reference to the currently edited file**.
- Selecting an item in the map and click the  **Insert Reference** button from the **DITA Maps Manager** *(on page 3073)* toolbar.
- Select  **Insert Reference** from the **DITA Maps** menu.

Dragging and Dropping a File into the DITA Maps Manager

You can add a topic to a *DITA map* by dragging and dropping the file into the **DITA Maps Manager** *(on page 3073)*. You can drag and drop files from any of the following:

- Your OS file system explorer.
- The **Project** view *(on page 413)*.
- The **Open/Find Resource** view *(on page 433)*.

Adding topics this way will not open the **Insert Reference** dialog box, but you can adjust all the same properties by invoking the contextual menu from the topic and selecting **Edit Properties**.

Adding a New Topic to a Map

To add a new topic to a map, follow these steps:

1. In the **DITA Maps Manager** *(on page 3073)*, right-click the node in the current map where you want to add the new topic.
2. Select one of the following actions:
   - **Append Child > New** - Select this action to insert the new topic as a child of the selected node. This action opens a **New** file dialog box *(on page 3139)* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
   - **Insert Before > New** - Select this action to insert the new topic as a sibling to the current node, before it. This action opens a **New** file dialog box *(on page 3139)* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
   - **Insert After > New** - Select this action to insert the new topic as a sibling to the current node, after it. This action opens a **New** file dialog box *(on page 3139)* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
   - **Duplicate** - Select this action to create a copy of the selected topic and insert it as a sibling. This action opens a dialog box that allows you to choose the file name and location for the newly created copy of the topic. After you have selected the name and path for your new topic, click **OK**.

     

     Note:
     The value of the root ID is generated taking the *Use the file name as the value of the root ID attribute* option from the **DITA > Topics** preferences page *(on page 282)* into account. When the option is deselected, a unique ID is generated.

   Step Result: The new topic is now referenced (as a `<topicref>`) in the *DITA map* at the location where you inserted it and the new topic is opened in the editor.
3. Save the *DITA map*.

Adding Multiple Skeleton Topics at Once

Oxygen XML Editor includes a feature in the **DITA Maps Manager** *(on page 3073)* that allows you to quickly create multiple skeleton topics at once and you can specify their hierarchical structure within the *DITA map (on page 3419)*.

To access this feature, right-click a node in the **DITA Maps Manager** where you want the new topics to be inserted and select **Fast Create Topics**. This opens the **Fast Create Topics** dialog box where you can configure the structure for the new topics.

For more information, see Fast Create Multiple DITA Topics *(on page 3141)*.

Adding Multiple References to the Same Topic in a Map

Oxygen XML Editor allows you to reuse entire topics by adding multiple references to the same topic in a *DITA map*. Whenever multiple references to the same topic are detected in the context of the current map in the **DITA Maps Manager** *(on page 3073)*, an indicator will appear in the top-right corner of the **Author** mode editor that shows the number of times the topic is referenced in the *DITA map*. It also includes navigation arrows that allow you to jump to the next or previous reference.

Remove Topics from a Map

You can remove topics from a map in a number of ways. Some ways to remove a topic from a map include:

- Highlight the topic and press the **Delete** or **Backspace** key on your keyboard.
- Highlight the topic and click the **Delete** button on the **DITA Maps Manager** *(on page 3073)* extended toolbar.

Related Information:
Fast Create Multiple DITA Topics *(on page 3141)*

Moving and Renaming Resources

You can move or rename resources referenced in your DITA project on disk directly from Oxygen XML Editor and you have the option of updating all the references to the moved or renamed resources. If the resources are referenced in the DITA map, you can do this from the **DITA Maps Manager** view *(on page 3073)*. You can also move and rename resources (DITA topics, maps, or other resources such as folders, images, HTML files, audio, video, text files, Markdown documents) from the **Project** view *(on page 413)*. If you have enabled Main Files support *(on page 3368)*, you will also have the option to update all the references to the moved or renamed resource.

Moving or Renaming DITA Resources (Topics or Maps)

To move or rename resources (such as topics, maps, or other referenced non-DITA resources) referenced directly in the DITA map, use one of the following actions available in the **Refactoring** submenu of the contextual menu when invoked on the resource in the **DITA Maps Manager** view *(on page 3073)*:

Refactoring > Move resource

This action allows you to change the location of a resource linked in the edited *DITA map* using the **Move resource** dialog box. This dialog box contains the following options:

- **Destination** - Specifies the target location of the edited resource.
- **File name** - Allows you to change the name of the edited resource.
- **Preview** - Select this button to display a preview of the changes Oxygen XML Editor is about to make.
- **Move** - Moves the edited resource in the target location on disk.
- **Cancel** - Cancels the **Move resource** operation. No changes are applied.

Refactoring > Rename resource

This action allows you to change the name of a resource linked in the edited *DITA map (on page 3419)* using the **Rename resource** dialog box. This dialog box contains the following options:

- **New name** - Presents the current name and allows you to change it.
- **Preview** - Select this button to display a preview of the changes Oxygen XML Editor is about to make.
- **Rename** - Executes the **Rename resource** operation.
- **Cancel** - Cancels the **Rename resource** operation. No changes are applied.

Note:
If a *root DITA map (on page 3424)* is not defined, the move and rename actions are executed in the context of the current *DITA map*.

Moving or Renaming Resources and Updating the References to Them Using the Project View

To move or rename DITA (topics, maps) or non-DITA resources (such as folders, images, HTML files, audio, video, text files, Markdown documents), you can simply follow the procedures described in Moving/Renaming Resources in the Project View *(on page 423)*. However, this approach will not give you the option to update the references to the moved or renamed resources.

To perform move or rename operation on resources while also updating all the references to them, use the following sets of procedures:

1. Enable *Main Files* support and add your *root DITA map (on page 3424)* to the *Main Files* folder by following the procedure found here: How to Enable Main Files Support in DITA *(on page 3368)*.
2. Move or rename resources and update the references to them by following the procedure found here: Moving or Renaming Non-DITA Resources and Updating the References to Them *(on page 3369)*.

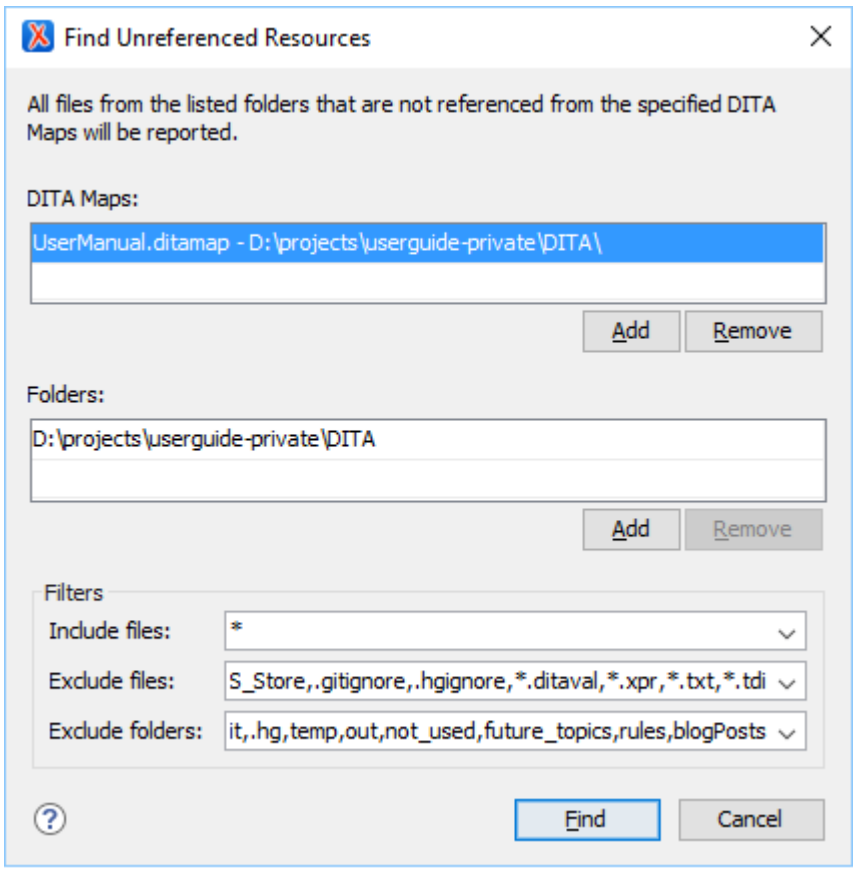
Main Files Support in DITA *(on page 3368)*
Finding Resources Not Referenced in DITA Maps *(on page 3098)*

Finding Resources Not Referenced in DITA Maps

Over the course of time, large projects can accumulate a vast amount of resources from a variety of sources. Especially in organizations with a large number of content authors or complex project structures, organizing the project resources can become a challenge. Over time a variety of actions can cause resources to become orphaned from *DITA maps (on page 3419)*. To assist you with organizing project resources, Oxygen XML Editor includes the **Find Unreferenced Resources** action, that searches for such resources.

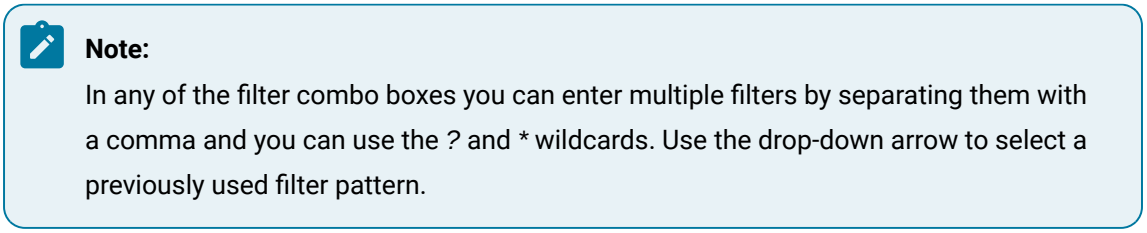
To perform this search, open the *DITA map* in the **DITA Maps Manager** *(on page 3073)*, invoke the contextual menu on the *map*, and select the **Find Unreferenced Resources** action. It can also be selected from the **DITA Maps** menu. This action opens the **Find Unreferenced Resources** dialog box, shown below.

Figure 763. Find Unreferenced Resources Dialog Box



The **Find Unreferenced Resources** dialog box includes the following options:

- **DITA Maps** - Provides a list of *DITA maps* to be included in the search and allows you to **Add** maps to the list or **Remove** them.
- **Folders** - Provides a list of folders to be included in the search and allows you to **Add** or **Remove** specific folders. All files from this list of folders that are not referenced from the maps specified in the **DITA Maps** list will be reported.
- **Filters** - Provides three combo boxes that allow you to filter the search to include or exclude certain files or folders:
  - **Include files** - Allows you to filter specific files to include in the search.
  - **Exclude files** - Allows you to filter specific files to exclude from the search.
  - **Exclude folders** - Allows you to filter specific folders to exclude from the search.



When you click the **Find** button, if the search operation finds unreferenced resources, they are displayed in the **Results** panel at the bottom of the editor. If you want to delete an unreferenced resource, you can right-click its result and select **Remove from Disk**. If you want to see the resource before deciding what to do with it, you can right-click its result and select **Show in Explorer**.

Inserting References in DITA Maps

A *DITA map (on page 3419)* may contain various types of references. The targets of the references can be a variety of references, such as chapters, maps, topics, topic sets, or key definitions. You can insert references to such targets with the **Insert Reference** dialog box *(on page 3099)*.

This section explains how to insert and configure references (such as topic references, topic groups, topic headings, and key definitions) in a *DITA map*.

Insert Reference Dialog Box

The **Insert Reference** dialog box allows you to insert and configure references in *DITA maps (on page 3419)*. There are numerous types of references that can be inserted into maps. They include references to topics, other maps, glossary terms, and keys. You can also use this dialog box to configure the attributes of a reference, add profiling or metadata, and define keys.

To open the **Insert Reference** dialog box, use one of the following methods:

- Select **Reference**, **Reference to the currently edited file**, or any of the other specific reference actions that are available from the **Append Child**, **Insert Before**, and **Insert After** submenus when invoking the contextual menu in the **DITA Maps Manager** *(on page 3073)*.
    - To insert the reference as a child of the current node, select the reference from the **Append Child** submenu.
    - To insert the reference as a sibling of the current node, below the current node in the map, select the reference from the **Insert After** submenu.
    - To insert the reference as a sibling of the current node, above the current node in the map, select the reference from the **Insert Before** submenu.

    Note:
    The content of these submenus depends on the node that is selected in the *DITA map* tree when the contextual menu is invoked. For example, if the selected node is a topic reference (`<topicref>`), its possible child nodes include the following elements: `<anchorref>`, `<chapter>`, `<keydef>`, `<mapref>`, `<topicgroup>`, `<topichead>`, `<topicref>`, `<topicset>`, and `<topicsetref>`.

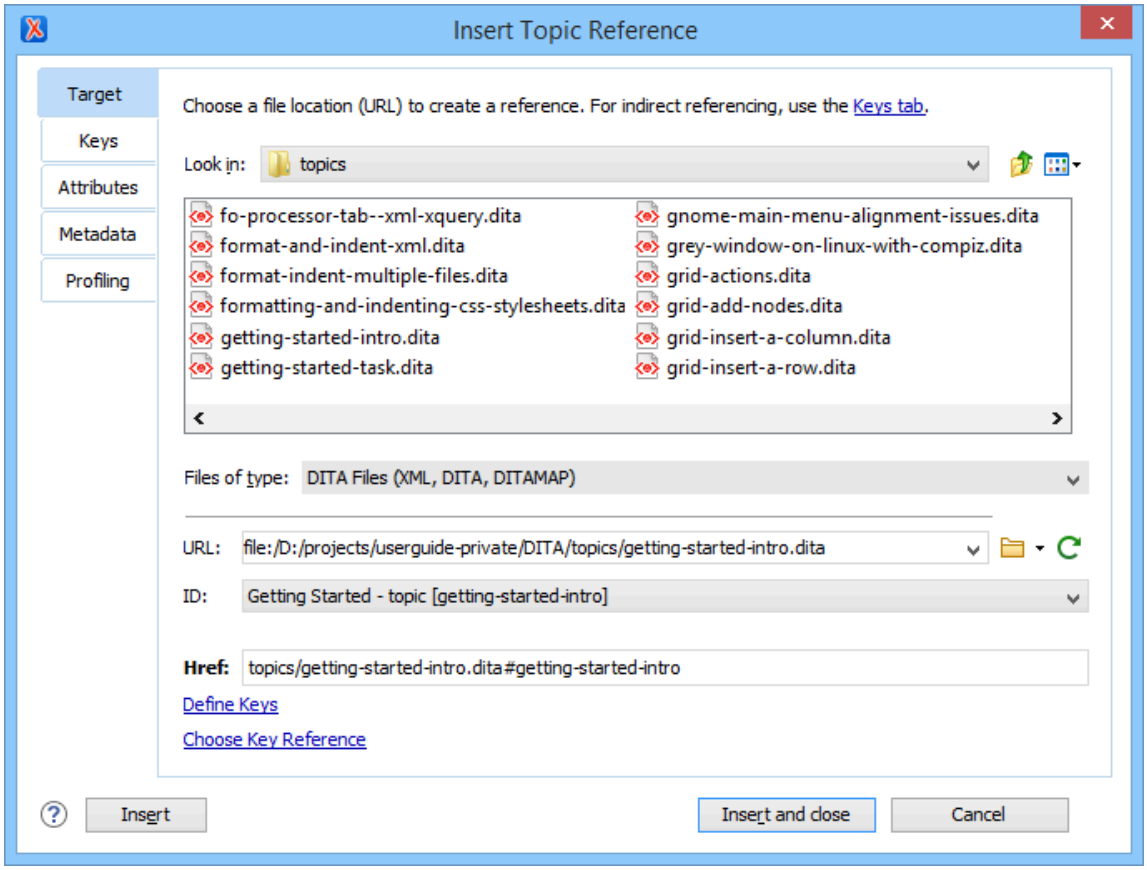
- Click the **Insert Reference** button on the **DITA Maps Manager** extended toolbar. This action will insert the reference as a sibling of the current node (below the current node in the map).
- Select **Insert Reference** from the **DITA Maps** menu. This action will insert the reference as a sibling of the current node (below the current node in the map).

For the **Reference** or **Reference to the currently edited file** actions, a **Reference type** drop-down list is displayed at the top of the **Insert Reference** dialog box and you can select the type of reference you want to insert. Depending on the place where the reference will be inserted, Oxygen XML Editor will propose only valid reference types. When you change the reference type, the fields in the various tabs of the dialog box are reconfigured depending upon the availability of the associated attributes. For the other reference actions in the **Append Child**, **Insert Before**, and **Insert After** submenus, the reference type is automatically chosen based upon the invoked action and you cannot change it.

The main section of the dialog box includes the following tabs: **Target**, **Keys**, **Attributes**, **Metadata**, and **Profiling**.

Target Tab

Figure 764. Insert Reference Dialog Box - Target Tab



The **Target** tab of the **Insert Reference** dialog box allows you to specify information about the target reference. It includes the following sections and fields:

Choose a file location section

You can browse for and select the source target file by using the **Look in** drop-down list, browsing buttons, or file window in this section. You can use the **Files of type** drop-down menu to narrow the list of possible file types that will be displayed.

URL

Displays the path to the target and allows you to select or change it by using the combo box or browsing buttons.

ID

The drop-down list displays all of the target elements that are available for the selected target URL.

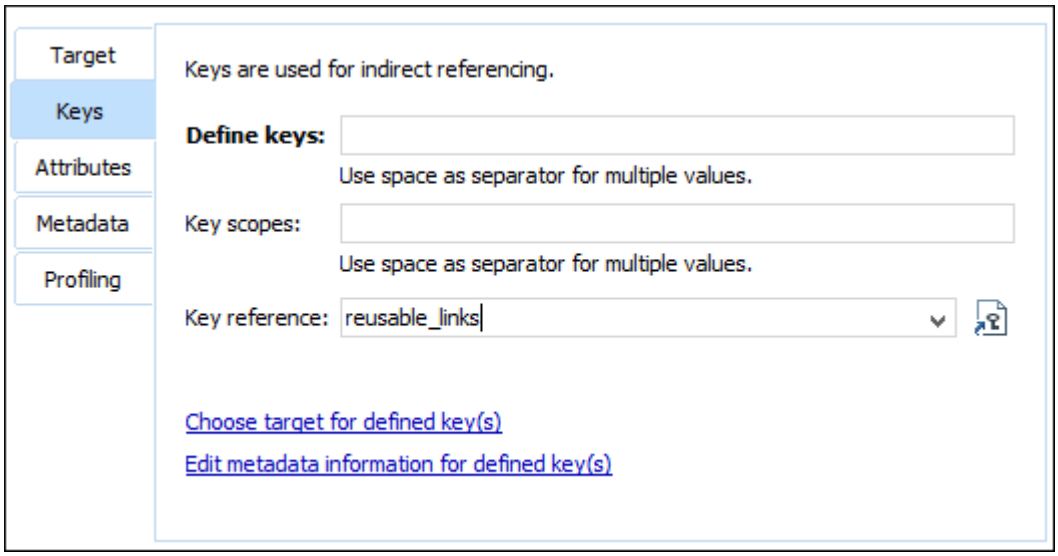
Href

The selected target automatically modifies this value to point to the corresponding `@href` attribute of the target element.

Note:
If the **Reference type** is a **Navigation Reference**, the **Href** field is changed to **Mapref**, since a `<navref>` element requires a `@mapref` attribute instead.

Keys Tab

Figure 765. Insert Reference Dialog Box - Keys Tab



The **Keys** tab allows you to use and define keys *(on page 3107)* for indirect referencing. For more information, see Working with Keys in DITA *(on page 3207)*. This tab includes the following:

Define keys

Use this text field to define the `@keys` attribute for the target.

Key scopes

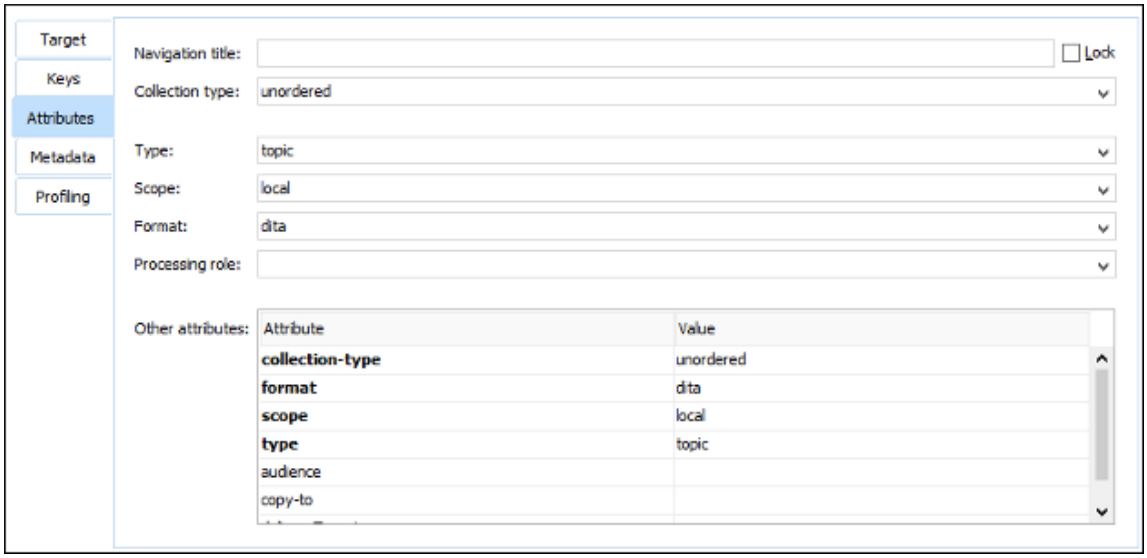
Use this text field to define or edit the value of a `@keyscope` attribute. *Key scopes* allow you to specify different sets of key definitions for different map branches.

Key reference

Instead of using the **Target** tab to select a file that contains the target reference, you can reference a key definition by using this text field. Use the **Choose key reference** button to access the list of keys that are already defined in the current *root map (on page 3424)*.

Attributes Tab

Figure 766. Insert Reference Dialog Box - Attributes Tab



The **Attributes** tab of the **Insert Reference** dialog box allows you to insert and edit attribute values for the target reference. This tab includes the following sections and actions:

Navigation title

This text field allows you to specify a custom navigation title for the target reference. If you want this attribute to always be populated with a detected value (based on the specifications for the target file), select the **Navigation title** checkbox for the **Always fill values for attributes** option in the **DITA** preferences page *(on page 280)*. For references to DITA resources, you can enforce the use of the specified title by selecting the **Lock** checkbox (otherwise, the topic `<title>` takes precedence).

Collection type

This drop-down list allows you to select the `@collection-type` attribute to create hierarchical linking between topics in a *DITA map* (for example, `unordered`, `sequence`, `choice`, `family`, `-dita-use-conref-target`).

Type

Allows you to select a `@type` attribute (such as `topic`, `task`, `concept`, etc.) for the target element. If you want this attribute to always be populated with a detected value (based on the specifications for the target file), select the **Type** checkbox for the **Always fill values for attributes** option in the **DITA** preferences page *(on page 280)*.

Scope

This property corresponds to the `@scope` attribute of the target element. It is populated automatically, based on the selected file type, unless its value for the selected target file is the same as the default attribute value. If you want this attribute to always be populated with a detected value based on the specifications (regardless of the default value), select the **Scope**

checkbox for the **Always fill values for attributes** option in the **DITA** preferences page *(on page 280)*.

Format

This property corresponds to the `@format` attribute of the target element. It is populated automatically, based on the selected file type, unless its value for the selected target file is the same as the default attribute value. If you want this attribute to always be populated with a detected value based on the specifications (regardless of the default value), select the **Format** checkbox for the **Always fill values for attributes** option in the **DITA** preferences page *(on page 280)*.

Processing Role

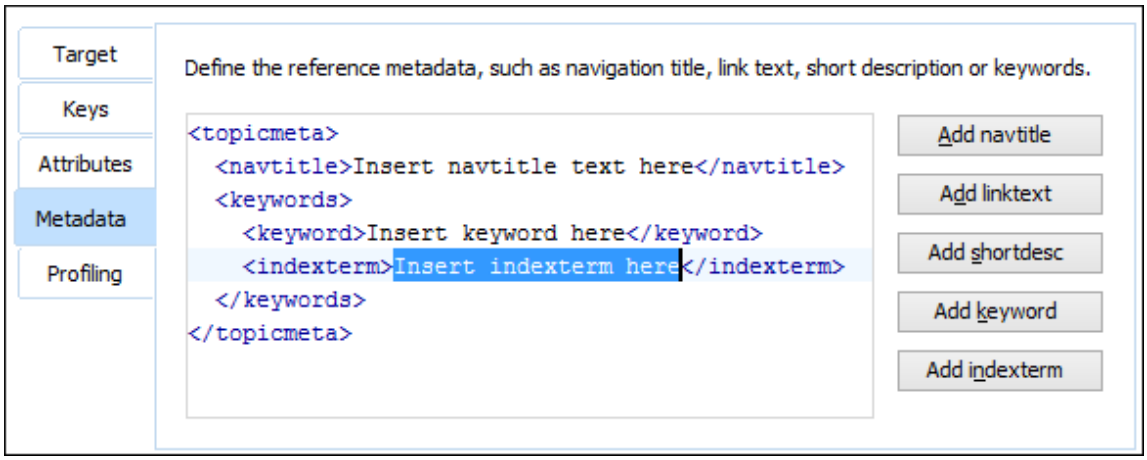
This drop-down list allows you to set the `@processing-role` attribute to one of the allowed values for DITA reference elements (for example, `resource-only`, `normal`, `-dita-use-conref-target`).

Other attributes table

This table contains the attributes that are available for the selected reference. You can use this table to insert or edit the values of any of the listed attributes. Clicking a cell in the **Value** column allows you to use the combo box to enter, edit, or select attribute values.

Metadata Tab

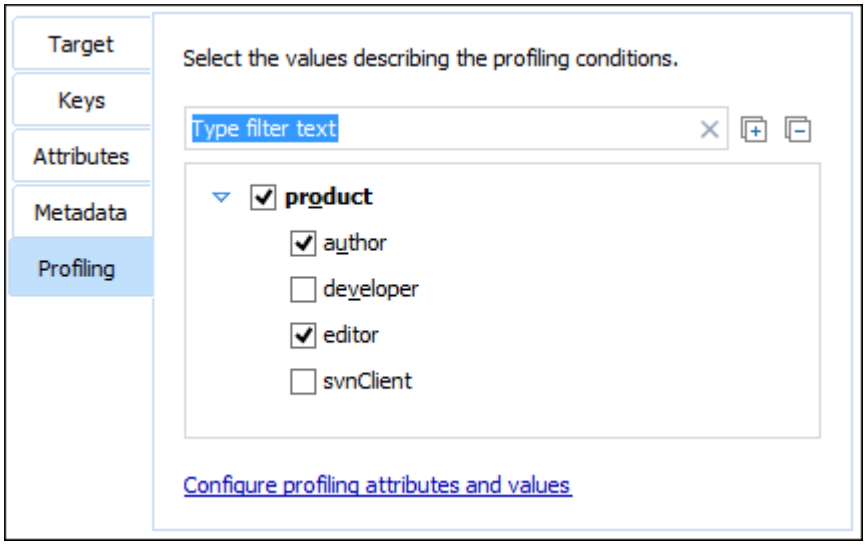
Figure 767. Insert Reference Dialog Box - Metadata Tab



The **Metadata** tab allows you to add metadata elements to the target reference. Use the buttons on the right side of the tab to insert specific metadata elements (you can add the following metadata elements: `<navtitle>`, `<linktext>`, `<shortdesc>`, `<keyword>`, `<indexterm>`). The metadata elements are inserted inside a `<topicmeta>` element. The editing window allows you to easily insert and modify the content of the metadata that will be inserted.

Profiling Tab

Figure 768. Insert Reference Dialog Box - Profiling Tab



The **Profiling** tab allows you to select or change profiling attributes for the selected reference. This tab displays profiling attributes and their values as determined by the following:

- If your *root map (on page 3424)* references a DITA *subject scheme map (on page 3424)* that defines values for the profiling attributes, those values are used.
- If your project defines project-level *(on page 3423)* configuration values for the profiling attributes *(on page 195)*, those values are used.
- If Oxygen XML Editor defines global-level *(on page 3420)* configuration values for the profiling attributes *(on page 195)*, they are used.
- Otherwise, a basic default set of profiling attributes and values are used.

When you modify a selection of values in this tab, the change will also automatically be reflected in the **Attributes** tab. For more information, see DITA Profiling / Conditional Text *(on page 3319)*.

Finalizing Your Insert Reference Configuration

Once you click **Insert** or **Insert and close**, the configured reference is added in the map.

Tip:
You can easily insert multiple references by keeping the **Insert Reference** dialog box opened, using the **Insert** button.

Related Information:
DITA Profiling / Conditional Text *(on page 3319)*
Working with Keys in DITA *(on page 3207)*

Inserting Topic Headings

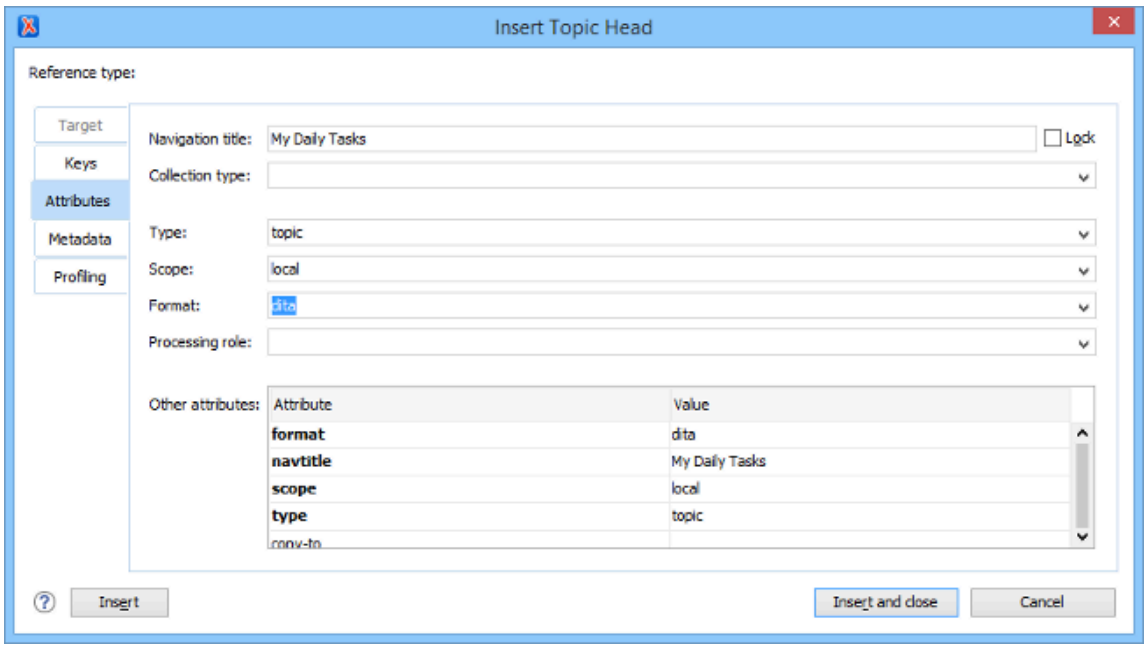
The `<topichead>` element provides a title-only entry in a navigation map, as an alternative to the fully-linked title provided by the `<topicref>` element.

You can insert a topic heading by doing the following:

- Select **Topic Head** from the **Append Child**, **Insert Before**, or **Insert After** submenus when invoking the contextual menu in the **DITA Maps Manager** view *(on page 3073)*.
- Open the *DITA map* in the XML editor *(on page 3072)* and select the **Insert Topic Heading** action from the main toolbar (or from the **Insert** submenu of the contextual menu).

Those actions open the **Insert Topic Head** dialog box *(on page 3099)* that allows you to easily insert a `<topichead>` element. A **Navigation title** (`@navtitle` attribute) is required but other attributes can also be specified from this dialog box (such as **Type**, **Scope**, **Format**, etc.)

Figure 769. Insert Topic Heading Dialog Box



Related Information:
Insert Reference Dialog Box *(on page 3099)*

Inserting Topic Groups

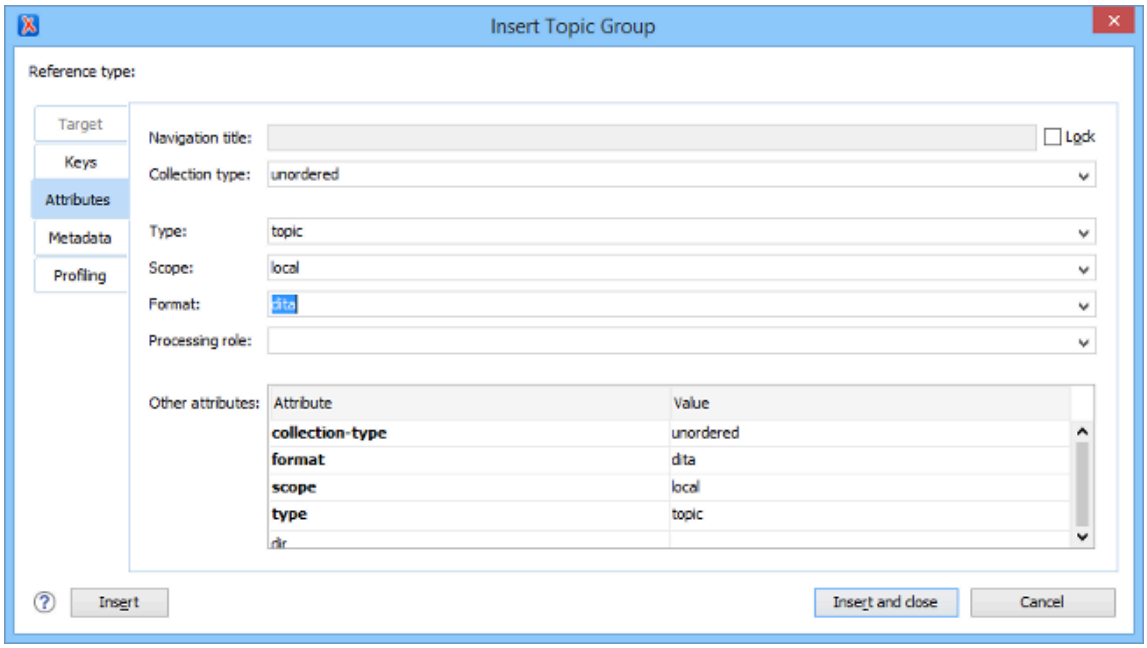
The `<topicgroup>` element identifies a group of topics (such as a concepts, tasks, or references) or other resources. A `<topicgroup>` can contain other `<topicgroup>` elements, allowing you to express navigation or table-of-contents hierarchies, as well as implying relationships between the containing `<topicgroup>` and its children. You can set the collection-type of a container `<topicgroup>` to determine how its children are related to each other. Relationships end up expressed as links in the output (with each participant in a relationship having links to the other participants by default).

You can insert a topic group by doing the following:

- Select **Topic Group** from the **Append Child**, **Insert Before**, or **Insert After** submenus when invoking the contextual menu in the **DITA Maps Manager** view *(on page 3073)*.
- Open the *DITA map* in the XML editor *(on page 3072)* and select the **Insert Topic Group** action from the main toolbar (or from the **Insert** submenu of the contextual menu).

Those actions open the **Insert Topic Group** dialog box *(on page 3099)* that allows you to easily insert a `<topicgroup>` element and various attributes can be specified (such as **Collection type**, **Type**, **Scope**, **Format**, etc.)

Figure 770. Insert Topic Group Dialog Box



Related Information:

Insert Reference Dialog Box *(on page 3099)*

Defining Keys in DITA Maps

DITA uses keys *(on page 3207)* to insert content that may have different values in various circumstances. Keys provide the means for indirect referencing in DITA. This can make it easier to manage and to reuse content. In DITA, keys are defined in maps and can then be reused and referenced throughout the whole structure of the map. It is considered best practice to create a separate submap that contains all of the key definitions and reference that submap in the *main (root) map (on page 3424)*. This makes it easier to manage since they're all in one location.

There are two types of key definitions that can be created in a map.

- Key with a value inside a *keyword*.
- Key with a target (for example, to target a resource such as an image or external link).

The following example is a *DITA map (on page 3419)* (a *key definition submap*) that contains some key definitions with various values for the *product* key and some targets to external URLs:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE map PUBLIC "-//OASIS//DTD DITA Map//EN" "map.dtd">
<map id="keydefs">
  <!-- product name -->
  <title>Key Definitions</title>
  <keydef keys="product" product="basic">
    <topicmeta>
      <keywords>
        <keyword>Basic Widget</keyword>
      </keywords>
    </topicmeta>
  </keydef>
  <keydef keys="product" product="pro">
    <topicmeta>
      <keywords>
        <keyword>Professional Widget</keyword>
      </keywords>
    </topicmeta>
  </keydef>
  <keydef keys="url_eula" href="https://www.example.com/eula.html" format="html"
     scope="external"/>
  <keydef keys="url_eula2" href="https://www.example.com/eula2.html" format="html"
     scope="external"/>
</map>
```

Note:
The profiling of the names is now contained in the map, where it only has to occur once to reuse throughout the whole map structure.

Key Definition with a Keyword Value

To define a key with a value inside a *keyword*, follow these steps:

1. **[Optional but Recommended]** Create a submap *(on page 3091)* that will contain all of your key definitions and reference the submap in your *main (root) map* (if you don't already have one created).
2. Open that map in the **DITA Maps Manager** *(on page 3073)*.
3. Right-click the map or an item in the map where you want to add the reference and select **Key Definition with Keyword** from the **Append Child**, **Insert Before**, or **Insert After** submenu (depending on where you want to insert the *key definition*). This opens an **Insert Key Definition** dialog box.
4. Enter the name of the key in the **Key** field.

5. Enter the key's value in the **Keyword** field.
6. Click **Insert and close**.

> **Tip:**
> If you need to profile the key or add other attributes, you can right-click the key definition in the **DITA Maps Manager**, select **Edit properties**, and configure them in the **Profiling** tab or **Attributes** tab, respectively.

Key Definition with a Target

To insert a *targeted key definition* (for example, to target a resource such as an image or external link), follow these steps:

1. **[Optional but Recommended]** Create a submap *(on page 3091)* that will contain all of your key definitions and reference the submap in your *main (root) map* (if you don't already have one created).
2. Open that map in the **DITA Maps Manager** *(on page 3073)*.
3. Right-click the map or an item in the map where you want to add the reference and select **Key Definition** from the **Append Child**, **Insert Before**, or **Insert After** submenu (depending on where you want to insert the *key definition* in the *DITA map*). This opens an **Insert Key Definition** dialog box.
4. Go to the **Keys** tab and enter the name of the key in the **Define keys** field.
5. Go to the **Target** tab and select a target resource (such as an image or external link).

> **Tip:**
> You can profile the key by using the **Profiling** tab and other attributes can also be defined in the **Attributes** tab.

6. Once you are done configuring the *targeted key definition*, click **Insert and close**.

DITA 1.3 Specification: Indirect Key-based Addressing

Edit Properties Dialog Box

The **DITA Maps Manager** view *(on page 3073)* includes a feature that allows you to view and edit the properties of a selected node. The **Edit properties** action is available on both the **DITA Maps Manager** toolbar and in the contextual menu. This action is also available in the contextual menu when you edit a *DITA map (on page 3419)* document in **Author** mode. The action opens the **Edit Properties** dialog box and it includes several tabs with various functions and fields that are initialized with values based upon the node where the action was invoked.

Note:

If you select multiple sibling nodes and invoke the **Edit properties** action, only the **Profiling** tab will be available and your modifications in that tab will be applied to all the selected nodes. If you select multiple nodes that are not on the same hierarchical level, the other tabs will also be available and your modifications will be applied to the parent node (the child nodes will inherit the attributes of the parent node).

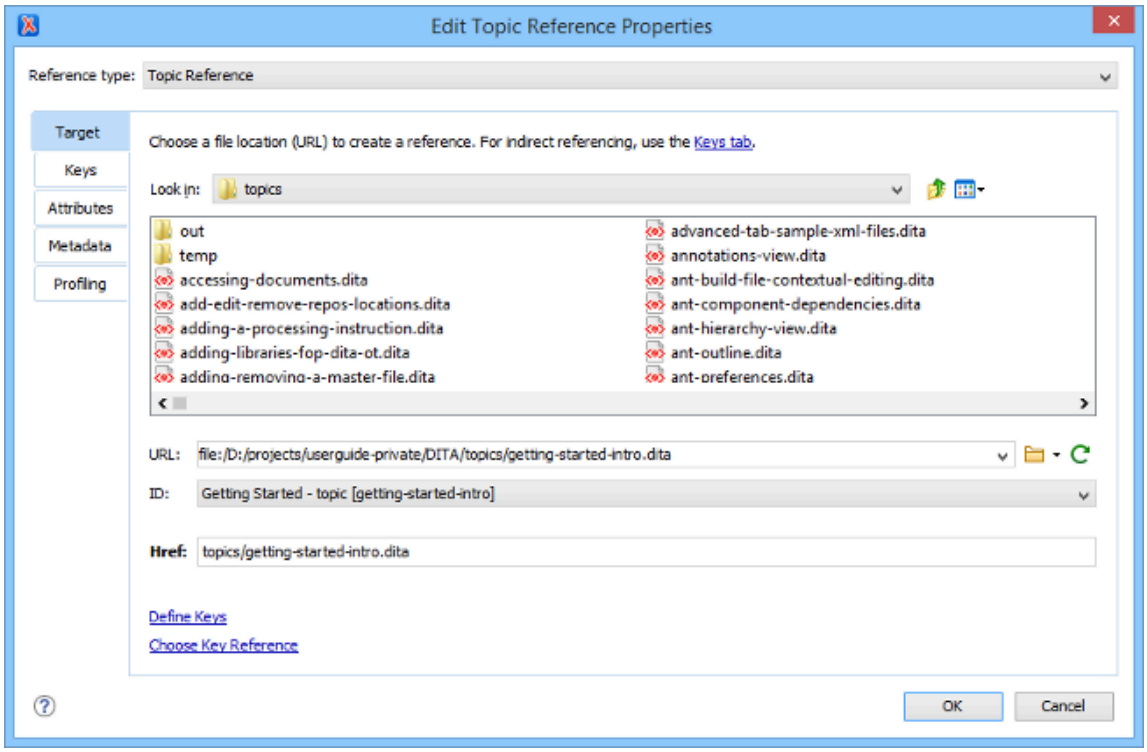
You can use the **Edit Properties** dialog box to modify or define attributes, metadata, profiling, or keys in *DITA maps* or topics. You can also use it to modify the title of *root maps (on page 3424)*.

At the top of the **Edit Properties** dialog box, the **Reference type** drop-down list displays the type of the selected node and it depends on the node where the action was invoked.

The main section of the dialog box includes the following tabs: **Target**, **Keys**, **Attributes**, **Metadata**, and **Profiling**. The availability of the tabs and their functions depend on the selected node. For example, if you invoke the action on a *root map (on page 3424)*, only the **Attributes**, **Metadata**, and **Profiling** tabs are accessible and the **Title** property can be configured. Also, if you select multiple nodes, only the **Profiling** tab is available.

Target Tab

Figure 771. Edit Properties Dialog Box - Target Tab



The **Target** tab of the **Edit Properties** dialog box displays information about the target node on which the action was invoked and allows you to change the target. It includes the following sections and fields:

Choose a file location section

You can browse for and select the source target file by using the **Look in** drop-down list, browsing buttons, or file window in this section. You can use the **Files of type** drop-down menu to narrow the list of possible file types that will be displayed.

URL

Displays the path to the target and allows you to select or change it by using the combo box or browsing buttons.

ID

The drop-down list displays all of the target elements that are available for the selected target URL.

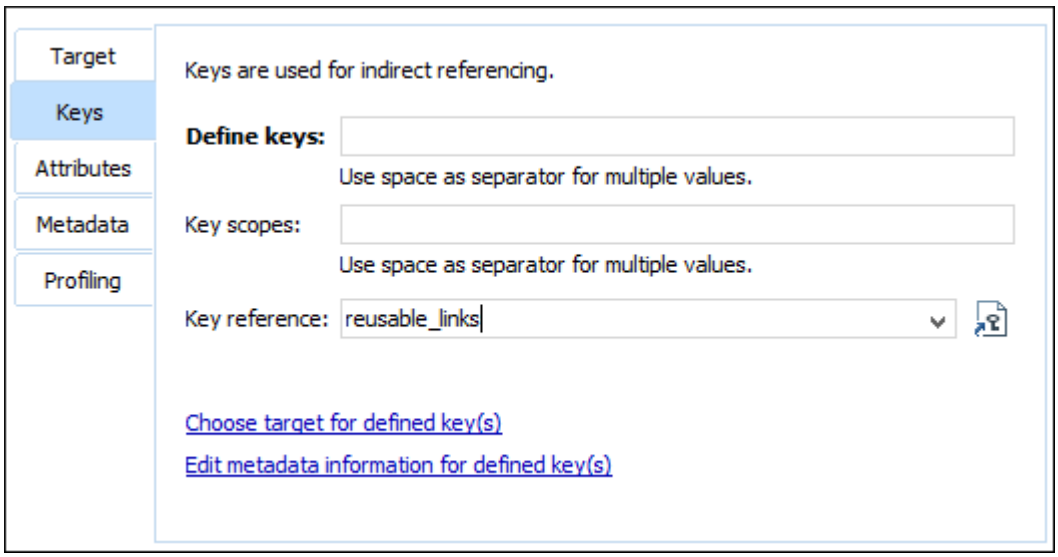
Href

The selected target automatically modifies this value to point to the corresponding `@href` attribute of the target element.

> **Note:**
> If the **Reference type** is a **Navigation Reference**, the **Href** field is changed to **Mapref**, since a `<navref>` element requires a `@mapref` attribute instead.

Keys Tab

Figure 772. Edit Properties Dialog Box - Keys Tab



The **Keys** tab allows you to use and define keys *(on page 3107)* for indirect referencing. For more information, see Working with Keys in DITA *(on page 3207)*. This tab includes the following:

Define keys

Use this text field to define the `@keys` attribute for the target.

Key scopes

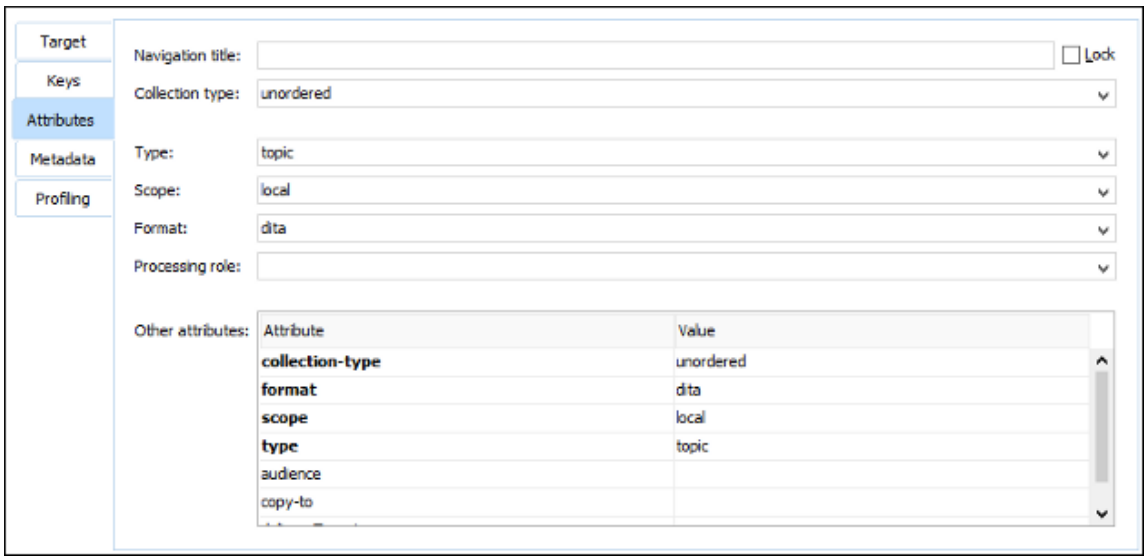
Use this text field to define or edit the value of a `@keyscope` attribute. *Key scopes* allow you to specify different sets of key definitions for different map branches.

Key reference

Use this combo box (or the **Choose key reference** button) to select a key that is already defined in the *root map (on page 3424)*.

Attributes Tab

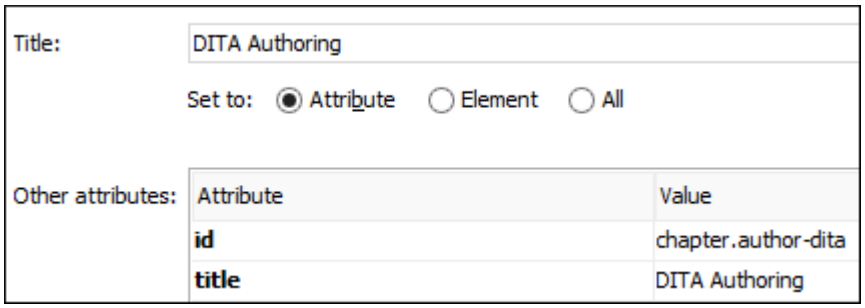
Figure 773. Edit Properties Dialog Box - Attributes Tab



The **Attributes** tab of the **Edit Properties** dialog box allows you to insert and edit attribute values for the target node where the action was invoked.

If the target is a *root map (on page 3424)*, the tab displays the title of the map. You can change it in the **Title** text field and assign it to an **Attribute**, **Element**, or **All**. However, if the title of the map contains elements other than plain text, the title is not editable and cannot be changed using this dialog box (you would need to open the DITA map in the main editor to edit the title).

Figure 774. Attributes Tab for a Root Map



For other types of targets, the tab includes the following sections and fields that can be used to edit the attributes of the target:

Navigation title

This text field allows you to specify a custom navigation title for the target reference. If you want this attribute to always be populated with a detected value (based on the specifications for the target file), select the **Navigation title** checkbox for the **Always fill values for attributes** option in the **DITA** preferences page *(on page 280)*. For references to DITA resources, you can enforce the use of the specified title by selecting the **Lock** checkbox (otherwise, the topic `<title>` takes precedence).

> **Tip:**
> You can also select the **Prefer navigation title for topicref rendering** option in the **DITA** preferences page *(on page 280)* to always enforce the use of the `@navtitle` value rather than selecting this **Lock** option on individual topics.

Collection type

This drop-down list allows you to select the `@collection-type` attribute to create hierarchical linking between topics in a *DITA map* (for example, `unordered`, `sequence`, `choice`, `family`, `-dita-use-conref-target`).

Type

Allows you to select a `@type` attribute (such as `topic`, `task`, `concept`, etc.) for the target element. If you want this attribute to always be populated with a detected value (based on the specifications for the target file), select the **Type** checkbox for the **Always fill values for attributes** option in the **DITA** preferences page *(on page 280)*.

Scope

This property corresponds to the `@scope` attribute of the target element. It is populated automatically, based on the selected file type, unless its value for the selected target file is the same as the default attribute value. If you want this attribute to always be populated with a detected value based on the specifications (regardless of the default value), select the **Scope** checkbox for the **Always fill values for attributes** option in the **DITA** preferences page *(on page 280)*.

Format

This property corresponds to the `@format` attribute of the target element. It is populated automatically, based on the selected file type, unless its value for the selected target file is the same as the default attribute value. If you want this attribute to always be populated with a detected value based on the specifications (regardless of the default value), select the **Format** checkbox for the **Always fill values for attributes** option in the **DITA** preferences page *(on page 280)*.

Processing Role

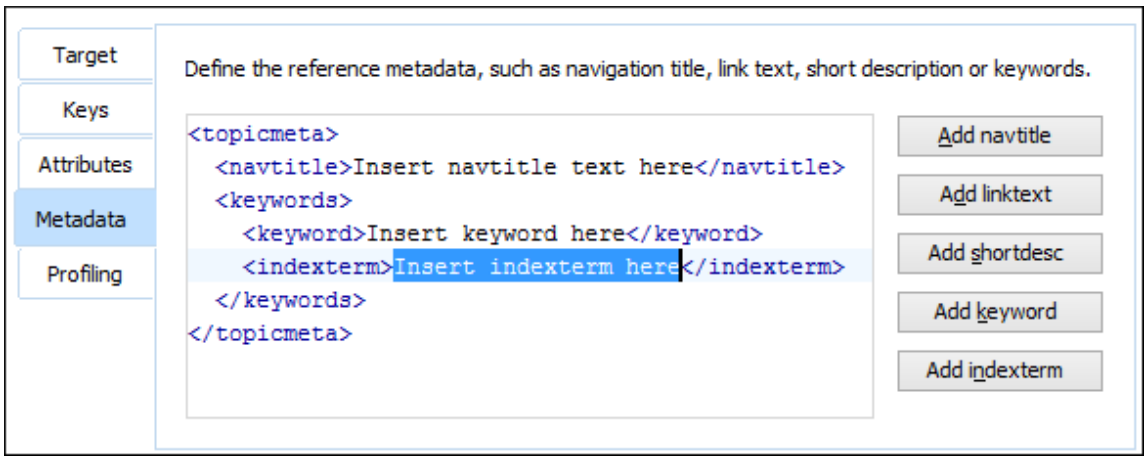
This drop-down list allows you to set the `@processing-role` attribute to one of the allowed values for DITA reference elements (for example, `resource-only`, `normal`, `-dita-use-conref-target`).

Other attributes table

This table contains the attributes that are available for the selected reference. You can use this table to insert or edit the values of any of the listed attributes. Clicking a cell in the **Value** column allows you to use the combo box to enter, edit, or select attribute values.

Metadata Tab

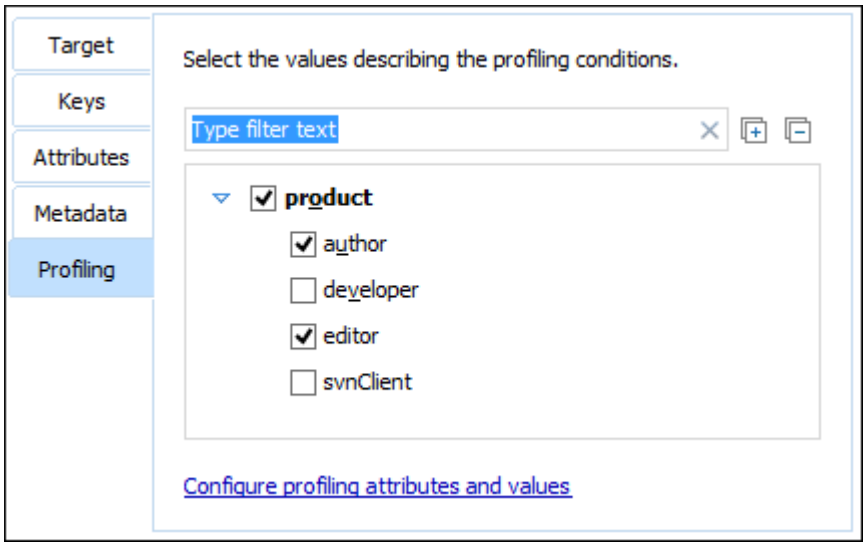
Figure 775. Edit Properties Dialog Box - Metadata Tab



The **Metadata** tab allows you to add metadata elements to the target node. Use the buttons on the right side of the tab to insert specific metadata elements (you can add the following metadata elements: `<navtitle>`, `<linktext>`, `<shortdesc>`, `<keyword>`, `<indexterm>`). The metadata elements are inserted inside a `<topicmeta>` element. The editing window allows you to easily insert and modify the content of the metadata that will be inserted.

Profiling Tab

Figure 776. Edit Properties Dialog Box - Profiling Tab



The **Profiling** tab allows you to select or change profiling attributes for the selected target nodes. This tab displays profiling attributes and their values as determined by the following:

- If your *root map (on page 3424)* references a DITA *subject scheme map (on page 3424)* that defines values for the profiling attributes, those values are used.
- If your project defines project-level *(on page 3423)* configuration values for the profiling attributes *(on page 195)*, those values are used.
- If Oxygen XML Editor defines global-level *(on page 3420)* configuration values for the profiling attributes *(on page 195)*, they are used.
- Otherwise, a basic default set of profiling attributes and values are used.

If you have a large list of profiling attributes, you can use the text filter field to search for attributes or values, and you can expand or collapse attributes by using the **Expand All**/**Collapse All** buttons to the right of the text filter or the arrow button to the left of the profiling attribute name.

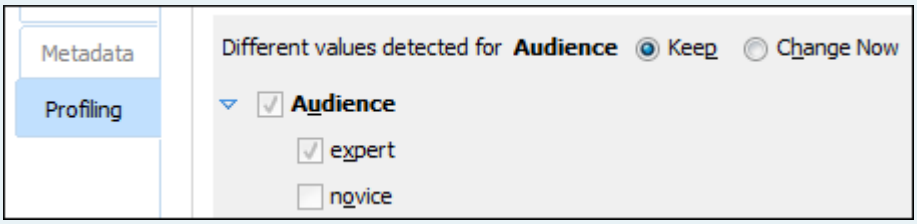
When you modify a selection of values in this tab, the change will also automatically be reflected in the **Attributes** tab. For more information, see DITA Profiling / Conditional Text *(on page 3319)*.

Note:

If you invoke the **Edit properties** action on a selection of multiple nodes that have different values for the same profiling attribute, a conflict panel will be displayed in the **Profiling** tab and you can choose between the following actions for resolving it:

- **Keep** - Preserves the current attribute values.
- **Change Now** - Allows you to edit the selection of values in this **Profiling** tab and the changes will be applied to all the selected nodes.

Figure 777. Profiling Conflict Panel



Finalizing Your Modifications

Once you click **OK**, all your changes are applied to the target node.

Working with Keys in DITA *(on page 3207)*

Generating a Table of Contents in DITA

In DITA, the order and hierarchy of the table of contents of a document is based directly on the *DITA map that defines the document (on page 3071)*. In most cases, the processor generates a table of contents (TOC)

based on the hierarchy of the topics in a DITA map. By default, each `<topicref>` element in a map represents a node in the TOC.

It is also possible to instruct DITA where the table of contents should occur (or other content lists, such as a list of figures or tables). If you want to instruct the processor to generate a table of contents at a particular location within your DITA map structure, you can use the `<toc>` element in a *bookmap (on page 3092)* (as in the example below). For more information about the `<toc>` element, see https://docs.oasis-open.org/dita/v1.2/os/spec/langref/toc.html.

Example:

```
<bookmap>
.....
  <frontmatter>
    <booklists>
      <toc href="chapter1.dita"/>
    </booklists>
  </frontmatter>
.....
```

Creating an Index in DITA

In DITA, indexes are created from `<indexterm>` elements. You can insert index term elements in the following:

- **The header of a topic:** In paginated media, such as a printed book or a PDF, this results in an index entry that points to the page where the topic starts, even if it is not the page in which the indexed term occurs.
- **In the `<topicref>` element in a map that references the topic:** This applies those index terms to that topic only when used in that map, allowing you to index topics differently in various publications. In paginated media, index entries point to the page where the topic starts.
- **In the body of a topic:** In paginated media, this results in an index entry that points to the page where the `<indexterm>` element occurs, even if that is not the page where the topic starts.

To add index terms to the text of a topic of the topic header, create the elements as you normally would in Oxygen XML Editor *(on page 3144)*. To add index terms to a map, open the map in the editor and add the elements, as you normally would, in a topic.

In some media, indexes will be generated automatically when index entries are found in the source. For other media, such as books, you may need to tell DITA where to place the index. For instance, to add an index to a *bookmap (on page 3417)*, you need to add an `<indexlist>` element to the `<backmatter>` of the book.

1. Open your *bookmap (on page 3092)* in the **DITA Maps Manager** *(on page 3073)*.
2. Right-click the *bookmap* and select **Append Child > Backmatter**.
   The **Insert Reference** dialog box *(on page 3099)* appears.
3. Click **Insert and Close** to insert the `<backmatter>` element.

4. Right-click the `<backmatter>` element and create a `<booklists>` element using **Append Child > Book Lists**.
5. Use the same steps to create an `<indexlist>` element.

CAUTION:
Adding *index* entries and an `<indexlist>` to your project creates an instruction to the DITA publishing routines to create an index. There is no guarantee that all DITA output types or third-party customizations obey that instruction or create the index the way you want it. Modifying the output may be necessary to get the result you want.

Resolving Topic References Through an XML Catalog

There are situations where you want to resolve references with an *XML Catalog (on page 3425)*:

- You customized your *DITA map (on page 3419)* to reference topics using URIs instead of local paths.
- You have URI content references in your DITA topic files and you want to map them to local files when the map is transformed.

In such situations, you have to add the catalog to Oxygen XML Editor. The **DITA Maps Manager** view *(on page 3073)* will solve the displayed topic refs through the added *XML catalog* URI mappings. The resolution through the XML catalog URI mappings are done only for reference values starting with the `urn:` prefix.

To add an *XML catalog* to the DITA *framework (on page 3420)*, follow these steps:

1. Create an *XML catalog* using the guidelines described in Working with XML Catalogs *(on page 838)*.
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Document Type Association**.
3. Select the **DITA** document type and use the **Edit**, **Duplicate**, or **Extend** button to open a **Document type** configuration dialog box *(on page 147)*.
4. Go to the **Catalogs** tab *(on page 171)*.
5. Click on the **Add** button to open a dialog box that allows you to add your created *XML Catalog* to the list.
6. After adding your catalog, click **OK**. You may need to reopen any currently edited files that use the new catalog or run a manual **Validate** action *(on page 786)* for the changes to take effect.

Note:
You could also add your created catalog to the list of global catalogs in the **XML Catalog** preferences *(on page 243)* page.

Adding a Custom URI Resolver to Oxygen XML Editor

You can use the `XMLUtilAccess.addPriorityURIResolver(URIResolver)` API to add your own priority URI resolver from a Workspace Access plugin *(on page 2585)*, allowing you to take control over how topic references in a DITA map are located or how references in DITA topics are resolved.

Publishing a DITA Map with References Resolved Through the XML Catalog

If you are publishing a DITA map that contains references to topics that need to be resolved through the XML catalog support in Oxygen XML Editor, you must enable the **fix.external.refs.com.oxygenxml** parameter in the **Parameters** tab of the transformation scenario configuration dialog box.

Chunking DITA Topics

By default, when a *DITA map (on page 3419)* is published to an online format, each topic becomes a separate page in the output. In some cases, you may want to combine multiple source topics into one output page. For instance, you may want to combine several types of information into a single page, or you may have chosen to create many small DITA topics for reuse purposes but feel they are too small to be useful to a reader by themselves. This is referred to as *chunking*.

To chunk DITA topics, you set the chunking attribute on the `<topicref>` that contains the sub-topics in a *DITA map*. There are several values that you can set on the chunking attribute (for example, `by-topic` or `to-content`). See the DITA documentation for full details. To achieve the effects you want in your topics and table of contents, you may also need to set the `@toc` and `@collection-type` attributes on the sub-topics or container topic to suitable values. See the DITA documentation for details.

You can set the `@collection-type` attribute on your topics using the **Edit Properties** action in the **DITA Maps Manager** *(on page 3073)*. To set the `@toc` and `@chunk` attributes, you must open the map file in the editor and add or edit the attributes directly (double-click the map icon in the **DITA Maps Manager** *(on page 3073)* to open the map in the editor).

DITA Map Validation and Completeness Check

You should validate your *DITA maps (on page 3419)* regularly to make sure that your maps and topics are valid, and all of the relationships between them are working. Changing one topic, image, or piece of metadata may create errors in references that rely on them. You may not discover these problems all at once. Validate your map to catch all of these kinds of problems. The longer you wait between validating your maps, the more difficult it may be to detect and correct any errors you find.

Validating a DITA Map

To validate a DITA, follow these steps:

1. In the **DITA Maps Manager** view *(on page 3073)*, make sure that the tab that holds your *root map (on page 3424)* is selected and that the **Context** selection is set either to the name of your *root map* or to `<current map>`.
2. It is a good practice to refresh your *DITA map* before running the validation process. To do so, select the *DITA map* in the **DITA Maps Manager** view and click **Reload (F5)**.
3. Click the **Validate and Check for Completeness** button from the **Validation** drop-down menu on the **DITA Maps Manager** toolbar to open the **DITA Map Completeness Check** dialog box *(on page 3119)*.

4. If you are using profiling, check the **Use DITAVAL filters** box and select the appropriate option.
5. Select any other options you want to check.
6. Click **Check** to run the validation process.

Result: A dialog box is displayed showing the progress of the operation. You can click the **Run in Background** button to close this dialog box so that you can continue working while the operation continues in the background and the progress would continue in the information ribbon at the bottom of the application.

Validation Process

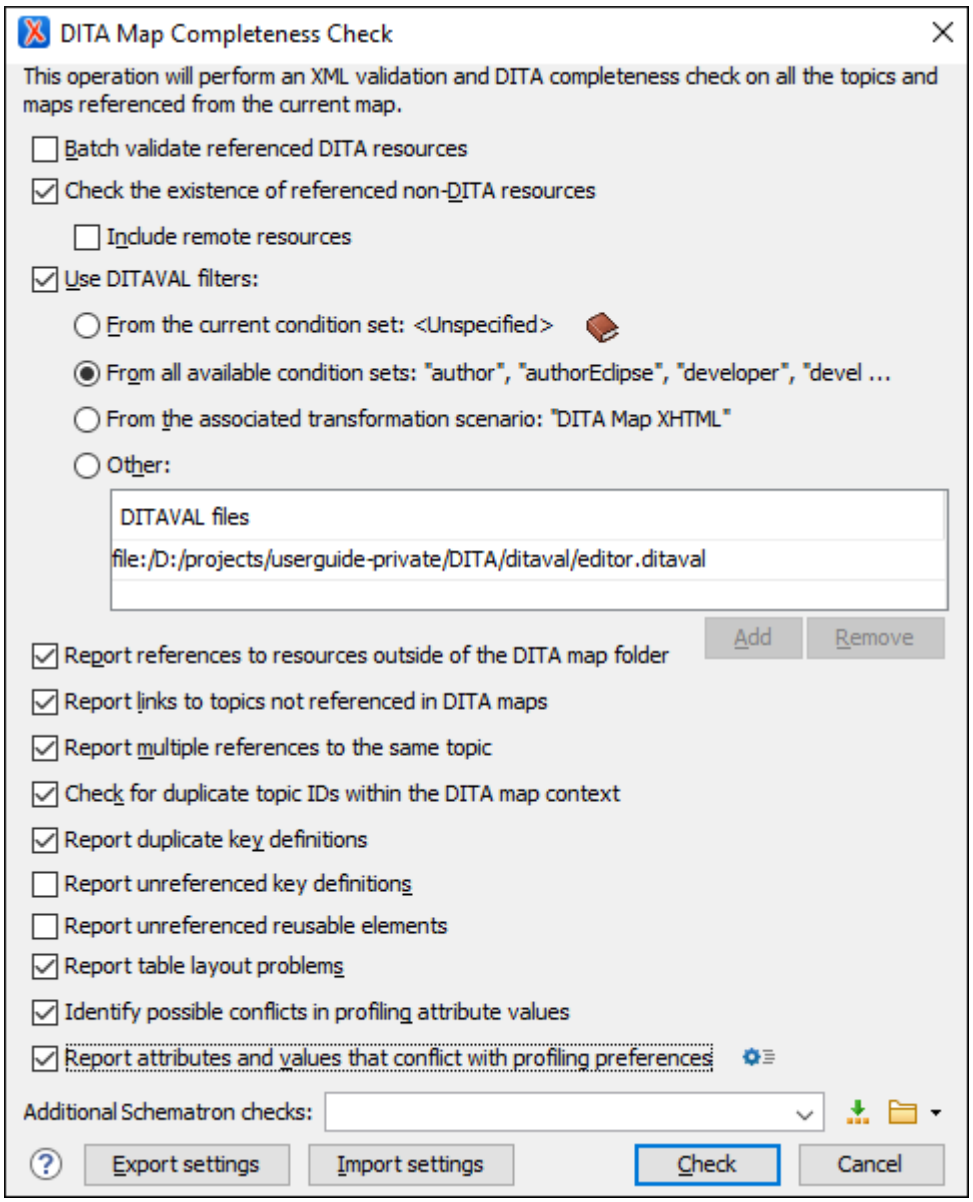
The validation process of a *DITA map* includes the following:

- Verifies that the file paths of the topic references are valid. For example, if an `@href` attribute points to an invalid file path, it is reported as an error in the message panel at the bottom of the editor.
- Validates each referenced topic and map. Each topic file is opened and validated against the appropriate DITA DTD. If another *DITA map* is referenced in the main one, the referenced *DITA map* is verified recursively, applying the same algorithm as for the main map.
- If errors or warnings are found, they are displayed in a separate message pane at the bottom of the editor and clicking them takes you to the location of the error or warning in the file where it was found.

DITA Map Completeness Check Dialog Box

The **DITA Map Completeness Check** dialog box allows you to configure the *DITA map* validation.

Figure 778. DITA Map Completeness Check Dialog Box



You can configure the validation process with the following options that are available in the **DITA Map Completeness Check** dialog box:

Batch validate referenced DITA resources

This option specifies the level of validation that applies to referenced DITA files:

- If the checkbox is left unchecked (default setting), the DITA files will be validated using the rules defined in the DTD or XML Schema declared in the document.
- If the checkbox is selected, the DITA files will be validated using rules defined in their associated validation scenario *(on page 798)*.

Check the existence of non-DITA references resources

Extends the validation of referenced resources to non-DITA files.

Include remote resources

Select this option if you want to check that remote referenced binary resources (such as images, movie clips, ZIP archives) exist at the specified location.

Use DITAVAL filters

The content of the map is filtered by applying a profiling condition set *(on page 3319)* before validation.

> **Note:**
> The validation process also takes branch filtering `<ditavalref>` elements into account as long as they appear before the referenced topics.

You can choose between the following options:

- **From the current condition set** - The map is filtered using the condition set currently applied in the **DITA Maps Manager** view *(on page 3073)*. Clicking the **Details** icon opens a topic in the Oxygen XML Editor User Guide that explains how to create a profiling condition set.
- **From all available condition sets** - For each available condition set, the map content is filtered using that set before validation.
- **From the associated transformation scenario** - The filtering condition set is specified explicitly as a DITAVAL file in the current transformation scenario associated with the *DITA map*.
- **Other DITAVAL files** - For each DITAVAL file from this list, the map content is filtered using the DITAVAL file before validation. Use the **Add** or **Remove** buttons to configure the list. The **Add** button opens a dialog box that allows you to select a local or remote path to a DITAVAL file. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 332)* button, or the browsing actions in the **Browse** drop-down list.

Report references to resources outside of the DITA map folder

If selected, it will report any references to DITA resources that are located outside the *main DITA map (on page 3424)* folder.

Report links to topics not referenced in DITA maps

Checks that all the topics referenced by other topics are also linked in the *DITA map*. Also reports related links defined in relationship tables whose target topics are not referenced in the DITA Map.

Report multiple references to the same topic

If selected, it will report warnings when a topic is referenced multiple times in the *DITA map*, unless a unique `@copy-to` attribute is used on the `<topicref>` element for any topic that is referenced multiple times.

For example, it will **not** report a warning if there is a topic referenced twice, but the second `<topicref>` has a `@copy-to` attribute set:

```
<topicref href="topic.dita"/>
.....
 <topicref href="topic.dita" copy-to="topic2.dita"/>
```

On the other hand, it **will** report a warning if there is a topic referenced twice and none of the reference-type elements has a `@copy-to` attribute set or both of them have the `@copy-to` attribute set to the same value:

```
<topicref href="topic.dita" copy-to="topic2.dita"/>
......
 <topicref href="topic.dita" copy-to="topic2.dita"/>
```

Check for duplicate topic IDs within the DITA map context

Checks for multiple topics with the same ID in the context of the entire map.

Report duplicate key definitions

Checks the *DITA map* for multiple key references with the same key defined for them. This is helpful because if you have two different resources with the same value for the `@keys` attribute, all references will point to the first one encountered and the other will be ignored.

Note:
This option takes *key scopes (on page 3239)* into account. For example, if you have something like this:

```
<topicref href="t2.dita" keys="k2"/>
    <topicgroup keyscope="ks">
        <topicref href="t2.dita" keys="k2"/>
    </topicgroup>
```

it will not report the "k2" key as a duplicate because it is defined in a *key scope (on page 3239)* on the second occurrence.

Report unreferenced key definitions

Checks the entire *DITA map* and reports any key definitions that are not referenced anywhere. Note that if the **Use DITAVAL filters** option is selected, this check will search for unreferenced key definitions based upon your selected filter.

Report unreferenced reusable elements

Checks the entire *DITA map* and reports any detected reusable elements that are not referenced anywhere. It looks for elements that have an *ID* specified in the following types of topic references:

- Any `<topicref>` that contains a `@processing-role` attribute set to **resource-only**.
- Any other referenced topic that contains elements that are reused elsewhere through a `@conref` or `@conkeyref`.

Report table layout problems

Looks for table layout problems. The types of errors that may be reported include:

- If a row has fewer cells than the number of columns detected.
- For a *CALS* table, if a cell has a vertical span greater than the available rows count.
- For a *CALS* table, if the number of `<colspecs>` is different than the number of columns detected from the table `@cols` attribute.
- For a *CALS* table, if the number of columns detected from the table `@cols` attribute is different than the number of columns detected in the table structure.
- For a *CALS* table, if the value of the `@cols`, `@rowsep`, or `@colsep` attributes are not numeric.
- For a *CALS* table, if the `@namest`, `@nameend`, or `@colname` attributes point to an incorrect column name.

Identify possible conflicts in profile attribute values

When the profiling attributes of a topic contain values that are not found in parent topic profiling attributes, the content of the topic is overshadowed when generating profiled output. This option reports these possible conflicts.

Report attributes and values that conflict with profiling preferences

Looks for profiling attributes and values that are not defined in the **Profiling / Conditional Text** preferences page *(on page 195)* (you can click the **Profiling Preferences** button to open this preferences page). It also checks if profiling attributes defined as *single-value* have multiple values set in the searched topics.

Additional Schematron checks

Allows you to select a Schematron file that Oxygen XML Editor will use for the validation of DITA resources. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 332)* button, or the browsing actions in the **Browse** drop-down list.

Advanced Tip:
Some APIs are available that retrieve information about DITA keys that are referenced within a topic. The APIs can be called from XSLT Stylesheets (including XML Refactoring operations) or Schematron schemas. For details, see API Documentation: DITAXSLTExtensionFunctionUtil.

Export settings

Allows you to export the settings assigned in this dialog box to an XML file that you can share with other users or use on other systems.

Import settings

Allows you to import settings for this dialog box from an XML file that was created by the **Export settings** action.

Check

Use the **Check** button to begin the validation process. The options that you choose in this dialog box are preserved between sessions.

Tip:
This function can be executed from an automated command-line script, for more details, see Scripting Oxygen *(on page 3383)*.

Related information
DITA Maps Manager *(on page 3073)*

DITA Map Author Mode Actions

A variety of actions are available for DITA map documents that can be found in **DITA** menu, toolbar, contextual menu, and the *Content Completion Assistant (on page 3418)*.

DITA Map Toolbar and Menu Actions

When a *DITA map* is opened in **Author** mode, the following default actions are available on the DITA Map toolbar (by default, they are also available in the **DITA** menu and in various submenus of the contextual menu):

Insert New DITA Resource

Opens a **New** DITA file dialog box *(on page 3138)* where you can choose the type of DITA document to create and inserts a reference to it at the current position within the map.

Insert Topic Reference

Opens the **Insert Reference** dialog box *(on page 3099)* where you can configure a topic reference and inserts it at the current position within the map.

Insert Key Definition with Keyword

Opens a dialog box where you can choose the name of a key and its keyword value and inserts the key definition at the current position within the map.

Reuse Content

Opens the **Reuse Content** dialog box *(on page 3224)* that allows you to insert and configure a content reference (`@conref`), or a content key reference (`@conkeyref`) at the cursor position.

Insert Topic Heading

Opens the **Insert Reference** dialog box *(on page 3099)* that allows you to insert a topic heading at the cursor position.

Insert Topic Group

Opens the **Insert Reference** dialog box *(on page 3099)* that allows you to insert a topic group at the cursor position.

Insert Relationship Table

Opens a dialog box that allows you to configure the relationship table to be inserted. The dialog box allows you to configure the number of rows and columns of the relationship table, if the header will be generated and if the title will be added.

Relationship Table Properties

Allows you to change the properties of rows in relationship tables.

Insert Relationship Row

Inserts a new table row with empty cells. The action is available when the cursor position is inside a table.

Insert Relationship Column

Inserts a new table column with empty cells after the current column. The action is available when the cursor position is inside a table.

Delete Relationship Column

Deletes the table column where the cursor is located.

Delete Relationship Row

Deletes the table row where the cursor is located.

Move Up

Moves the selected node up one position on its same level.

Move Down

Moves the selected node down one position on its same level.

Promote(Alt + LeftArrow)

Moves the selected node up one level to the level of its parent node.

Demote(Alt + RightArrow)

Moves the selected node down one level to the level of its child nodes.

DITA Map Contextual Menu Actions

The following actions are available in the contextual menu when editing in **Author** mode (most of them are also available in the **DITA** menu at the top of the interface):

Add File to Review Task

This action can be used to add the current document to a task in the **Content Fusion Tasks Manager** view. **Oxygen Content Fusion** is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on *(on page 2651)*. To fully take advantage of all of the benefits and features of **Content Fusion**, your organization will need an **Oxygen Content Fusion Enterprise Server**. For more information, see the **Oxygen Content Fusion** website.

Edit Properties

Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see Edit Properties Dialog Box *(on page 3109)*.

Cut (Ctrl + X (Command + X on macOS))

Removes the currently selected content from the document and places it in the clipboard.

Copy (Ctrl + C (Command + C on macOS))

Places a copy of the currently selected content in the clipboard.

Paste (Ctrl + V (Command + V on macOS))

Inserts the current clipboard content into the document at the cursor position.

Paste special submenu

This submenu includes the following special paste actions that are specific to the DITA *framework*:

Paste as content reference

Inserts a content reference (a DITA element with a `@conref` attribute) to the DITA XML element from the clipboard. An entire DITA XML element with an ID attribute must be present in the clipboard when the action is invoked. The `conref` attribute will point to this ID value.

Paste as content key reference

Allows you to indirectly reference content using the `@conkeyref` attribute. When the DITA content is processed, the key references are resolved using key definitions from *DITA maps (on page 3419)*. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the **Context** combo box points to the correct map that stores the keys.

3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Paste as link

Looks for the first element with an ID value in the clipboard and inserts an `<xref>` that points to that element. If no elements with an ID value are found, a message will appear that informs you that to use this action, the clipboard contents must include at least one element with a declared ID.

Paste as link (keyref)

Inserts a link to the element that you want to reference. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the **Context** combo box points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Insert submenu

This submenu includes the following insert actions that are specific to the DITA Map *framework*:

 **Insert New DITA Resource**

Opens a **New** DITA file dialog box *(on page 3138)* where you can choose the type of DITA document to create and inserts a reference to it at the current position within the map.

 **Insert Topic Reference**

Opens the **Insert Reference** dialog box *(on page 3099)* where you can configure a topic reference and inserts it at the current position within the map.

 **Insert Key Definition with Keyword**

Opens a dialog box where you can choose the name of a key and its keyword value and inserts the key definition at the current position within the map.

 **Reuse Content**

Opens the **Reuse Content** dialog box *(on page 3224)* that allows you to insert and configure a content reference (`@conref`), or a content key reference (`@conkeyref`) at the cursor position.

Insert Topic Heading

Opens the **Insert Reference** dialog box *(on page 3099)* that allows you to insert a topic heading at the cursor position.

Insert Topic Group

Opens the **Insert Reference** dialog box *(on page 3099)* that allows you to insert a topic group at the cursor position.

Insert Entity

Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- #<*decimal value*> - e.g. #65
- &#<*decimal value*> - e.g. &#65
- #x<*hexadecimal value*> - e.g. #x41
- &#x<*hexadecimal value*> - e.g. &#x41

Relationship Table > Insert Relationship Table

Opens a dialog box that allows you to configure the relationship table to be inserted. The dialog box allows you to configure the number of rows and columns of the relationship table, if the header will be generated and if the title will be added.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements listed in the **ID Options** dialog box that are found in the current selection.

Note:
The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `@id` attribute.

Search References

Finds the references to the `@href` or `@keys` attribute value of the topic/map reference element at the current cursor position, in all the topics from the current *DITA map* (opened in the **DITA Maps**

Manager view *(on page 3073)*). The current topic/map reference element must have an `@href` or `@keys` attribute defined to complete the search.

Show Key Definition

Available for elements that have a `@conkeyref` or `@keyref` attribute set (or elements with an ancestor element that has a `@conkeyref` or `@keyref` attribute). It computes the key name and opens the *DITA map (on page 3419)* that contains the definition of the key with the element that defines that key selected.

Select submenu

This submenu allows you to select the following:

Element

Selects the entire element at the current cursor position.

Content

Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

Parent

Selects the entire parent element at the current cursor position.

Text submenu

This submenu contains the following actions:

To Lower Case

Converts the selected content to lower case characters.

To Upper Case

Converts the selected content to upper case characters.

Capitalize Sentences

Converts to upper case the first character of every selected sentence.

Capitalize Words

Converts to upper case the first character of every selected word.

Count Words

Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

Note:
The content marked as deleted with *change tracking (on page 3424)* is ignored when counting words.

Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on macOS))

Converts a sequence of hexadecimal characters to the corresponding Unicode character *(on page 473)*. The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the `0x` or `0X` prefix. Examples of valid sequences and the characters they will be converted to:

- `0x0045` will be converted to `E`
- `0X0125` to `ĥ`
- `265` to `ŋ`
- `2190` to `←`

> **Note:**
> For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent *(on page 476)*.

Refactoring submenu

Contains a series of actions designed to alter the XML structure of the document:

Toggle Comment

Encloses the currently selected text in a comment, or removes the comment if it is commented.

Move Up (Alt + UpArrow (Option + UpArrow on macOS))

Moves the current node or selected nodes in front of the previous node.

Move Down (Alt + DownArrow (Option + DownArrow on macOS))

Moves the current node or selected nodes after the subsequent node.

Split Element (Alt + Shift + D (Ctrl + Option + D on macOS))

Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

Join Elements

Joins two adjacent *block elements (on page 3417)* that have the same name. The action is available only when the cursor position is between the two adjacent *block elements*. Also, joining two *block elements* can be done by pressing the **Delete** or

Backspace keys and the cursor is positioned between the boundaries of these two elements.

Surround with Tags (Ctrl + E (Command + E on macOS))

Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.

- If the **Position cursor between tags** option *(on page 220)* is selected in the **Content Completion** preferences page, the cursor is placed between the start and end tag.
- If the **Position cursor between tags** option *(on page 220)* is not selected in the **Content Completion** preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

Surround with '[tag]' (Ctrl + ForwardSlash (Command + ForwardSlash on macOS))

Surround the selected content with the last tag used.

Rename Element

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the **Rename** dialog box.

Delete Element Tags

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the **Delete** or **Backspace** keys.

Remove All Markup

Removes all the XML markup inside the selected block of content and keeps only the text content.

Remove Text

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

Attributes Refactoring Actions

Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

Add/Change attribute

Allows you to change the value of an attribute or insert a new one.

Convert attribute to element

Allows you to change an attribute into an element.

Delete attribute

Allows you to remove one or more attributes.

Rename attribute

Allows you to rename an attribute.

Replace in attribute value

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

Comments Refactoring Actions

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

Delete comments

Allows you to delete comments found inside one or more elements.

Elements Refactoring Actions

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

Delete element

Allows you to delete elements.

Delete element content

Allows you to delete the content of elements.

Insert element

Allows you to insert new elements.

Rename element

Allows you to rename elements.

Unwrap element

Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

Wrap element

Allows you to surround elements with element tags.

Wrap element content

Allows you to surround the content of elements with element tags.

Fragments Refactoring Actions

Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

Insert XML fragment

Allows you to insert an XML fragment.

Replace element content with XML fragment

Allows you to replace the content of elements with an XML fragment.

Replace element with XML fragment

Allows you to replace elements with an XML fragment.

Review submenu

This submenu includes the following actions:

Track Changes

Enables or disables the *Track Changes (on page 3424)* support for the current document.

Accept Change(s) and Move to Next

Accepts the *Tracked Change (on page 3424)* located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a *deletion* or *insertion* change, only the selected content is accepted.

Accept All Changes

Accepts all *Tracked Changes (on page 3424)* in the current document.

Reject Change(s) and Move to Next

Rejects the *Tracked Change (on page 3424)* located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a *deletion* or *insertion* change, only the selected content is rejected.

Reject All Changes

Rejects all *Tracked Changes (on page 3424)* in the current document.

Comment Change

Opens a dialog box that allows you to add a comment to an existing *Tracked Change (on page 3424)*. The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

Highlight

Enables the highlighting tool that allows you to mark text in your document.

Colors

Allows you to select the color for highlighting text.

Stop highlighting

Use this action to deactivate the highlighting tool.

Remove highlight(s)

Use this action to remove highlighting from the document.

 **Add Comment**

Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).

 **Show/Edit Comment**

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

 **Remove Comment**

Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.

 **Manage Reviews**

Opens the **Review** view *(on page 675)*.

Folding submenu

This submenu includes the following actions:

 **Toggle Fold**

Toggles the state of the current fold.

 **Collapse Other Folds**

Folds all the elements except the current element.

 **Collapse Child Folds**

Folds the elements indented with one level inside the current element.

 **Expand Child Folds**

Unfolds all child elements of the currently selected element.

 **Expand All**

Unfolds all elements in the current document.

About Element >  Go to Definition

Moves the cursor to the definition of the current element.

Inspect Styles

Opens the **CSS Inspector** view *(on page 651)* that allows you to examine the CSS rules that match the currently selected element.

Options

Opens the Author mode preferences page *(on page 183)* where you can configure various options with regard to the **Author** editing mode.

Floating Contextual Toolbar for DITA

Oxygen XML Editor includes a dynamic feature where certain editing contexts will trigger a floating toolbar with common actions that are available in the current editing context.

The *floating contextual toolbar* is automatically displayed when editing DITA map documents when a `<topicref>` element is selected and it includes actions for moving the topic reference node up or down (or promoting/demoting the node).

DITA Map Drag/Drop Actions

Dragging a file from the **Project** view *(on page 413)* or **DITA Maps Manager** view *(on page 3073)* and dropping it into a *DITA map* document that is edited in **Author** mode creates a link to the dragged file (a `<topicref>` element, `<chapter>`, `<part>`, etc.) at the drop location.

Opening a Topic from a DITA Map in Author Mode

If a *DITA map* is open in the **Author** visual editing mode, you can open a referenced topic by clicking the  icon to the left of the particular topic. The source topic is opened in a new tab in the main editor.

Tip:
For information about customizing **Author** mode actions for a particular *framework (on page 3420)* (document type), see the Customizing the Author Mode Editing Experience for a Framework *(on page 2262)* section.

Related Information:
Customizing the Author Mode Editing Experience for a Framework *(on page 2262)*

Opening a DITA Map With Topic Content Resolved

It is possible to open a DITA map in the main editor with all the content from the referenced topics resolved and presented in one document. To do this, select the DITA map in the **DITA Maps Manager** view and click the **Open Map in Editor with Resolved Topics** toolbar button. This opens the *DITA map* in the main editor area with content from all topic references expanded in-place.

If the **Display referenced content** setting in the Author Preferences *(on page 183)* page is not selected, references to maps, topics, and content references can be expanded on demand by clicking the small **Expand Reference** expansion button located next to each element that contains a reference.

Content from the resolved topics that is referenced using a `@conref` or `@conkeyref` attribute is presented as read-only by default. To edit it, you must use the **Edit Reference** contextual menu action to open the source topic that contains the referenced content.

Editing Referenced Content Directly

If you want to edit the referenced content directly without having to open the source document, go to **Options > Preferences > Editor > Edit Modes > Author** and select the **Allow referenced content to be edited** option *(on page 186)*. The referenced content becomes editable in-place and saving the document will save all other modified topics.

Things to be Aware of When Enabling This Option:

- The references become editable only if the referenced topics are the root elements. If, for example, in the DITA map, there are references directly to subtopics embedded in a larger topic, those references will not be editable.
- If the content is stored in a CMS, you need to deselect the **Local files only** option *(on page 186)* to edit such remote referenced topics directly but this feature might not function properly with remote resources (it depends on the capabilities of the CMS connector).
- Since a single topic may be referenced in multiple places in the DITA map, be careful not to make conflicting changes to that topic.
- When modified topics are saved, the **Only modified content** option in the **Options > Preferences > Editor > Edit Modes > Author > Serialization** page *(on page 204)* is ignored.
- The toolbar has two DITA map-specific actions for inserting topic references and all DITA topic-specific actions that can be used to make changes in the referenced DITA topics.
- The content completion and schema-aware insertion strategies work in each referenced topic according to their respective schema.
- The contextual menu presents the relevant actions in each referenced topic.
- Validation works for each individual referenced topic but only if it contains modifications.

Working with DITA Topics

DITA is a structured writing format. Structure can have several meanings, all of which are relevant to DITA. This section includes information about working with DITA topics and the structure.

Information Types

The structure of a piece of content refers to how the words and images are selected and organized to convey information. One approach to structured writing is to divide content into discrete blocks that contain various types of information, and then to combine those blocks to form publications. DITA is based on this approach, and encourages the author to write in discrete blocks called topics. DITA provides three base topic types (concept, task, and reference), a number of extended topic types, and the capability to create new topic types through specialization.

Text Structure

Every piece of text is made up of certain text structures, such as paragraphs, lists, and tables. DITA supports text structures through XML elements such as `<p>`, `<ol>`, and `<simpletable>`. The DITA markup specifies the text

structures, but not how they will be published in various types of media. The formatting of text structures is determined by the output transformations and may be customized to meet the needs of various organizations and type of media.

Semantic Structure

Semantic structure is structure that shows the meaning of things. For example:

- A `<task>` element specifies that a block of content contains the description of a task.
- A `<codeblock>` element specifies that a block of text consists of programming code.
- A `<uicontrol>` element specifies that a word is the name of a control in a computer GUI.
- The `@platform` profiling attribute specifies that a particular piece of content applies only to certain computing platforms.

Semantic structure is important in a structured writing system because it allows both authors and readers to find content, and it allows processing scripts to process various pieces of content differently, based on their role or meaning. This can be used to do things such as filtering content related to a specific product so that you can produce documentation on many products from the same source.

There can be many forms of semantics captured in a document set. DITA captures some of these in topics and some of them in maps. If you are using a CMS, it may capture additional semantics.

Document Semantics

Documents consist of elements that may be made up of the same basic text structures as the rest of the text, but have a special function within the structure of the document. For instance, both tables of contents and indexes are lists, but they play a special role in the document. Chapters and sections are just sequences of paragraphs and other text structures, yet they are meaningful in the structure of the document. In some cases, such as indexes and tables of contents, these structures can be generated from semantic information embedded in the source. For instance, a table of contents can be built by reading the titles of chapters and sections. DITA provides elements to describe common document semantics.

Subject Matter Semantics

In some cases, the semantics of the content relate directly to the subject matter that the content describes. For instance, DITA supports tags that allow you to mark a piece of text as the name of a window in a software application (`<wintitle>`), or to mark a piece of text as applying only to a particular product.

Audience Semantics

In some cases, the semantics of the content relate to the audience that it is addressed to. For instance, a topic might be addressed to a particular role, or to a person with a particular level of experience. DITA provides an `<audience>` element to capture audience metadata.

Creating Topic Structures

Oxygen XML Editor provides a number of tools to help you create topic structures:

- *Content Completion Assistant (on page 3418)* - Shows you which elements can be created at the current position.
- **Model** view *(on page 555)* - Shows you the complete structure supported by the current element.
- **Outline** view *(on page 549)* - Shows you the current structure of your document.
- **DITA** toolbar - Helps you to easily insert many common structures.

Resources

For more information about getting started with DITA and how to work with DITA in Oxygen XML Editor, see our compiled collection of DITA-related webinars that are meant to help you with your journey into working with DITA: Webinars: Working with DITA in Oxygen.

Getting Started with DITA *(on page 3063)*

DITA Topics Document Type (Framework) *(on page 1373)*

Creating a New DITA Topic

The basic building block for DITA information is the DITA topic. DITA provides a variety of specialized topic types, the most common of which are:

- *Topic* - The base topic type from which all other topic types are specialized. Typically, it is used when a more specialized topic type is inappropriate.
- *Task* - For procedural information such as how to use a dialog box.
- *Concept* - For general, conceptual information such as a description of a product or feature.
- *Reference* - For reference information.

Oxygen XML Editor also supports numerous other specialized topic types that you will find templates for in the various folders in the **New** DITA file dialog box *(on page 3139)*. They include DITA 1.3 specializations, Lightweight DITA templates, MathML composites, Markdown documents, and other DITA specialized topic and *DITA map (on page 3419)* types such as *Glossentry*, *Troubleshooting*, *Questions and Answers*, *Bookmap (on page 3417)*, and *Subject Scheme Map (on page 3424)*.

To create a new DITA topic and add a reference to it in your *DITA map (on page 3419)*, follow these steps:

1. In the **DITA Maps Manager** *(on page 3073)*, right-click the node in the current map where you want to add the new topic.
2. Select one of the following actions:
   - **Append Child > New** - Select this action to insert the new topic as a child of the selected node. This action opens a **New** file dialog box *(on page 3139)* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
   - **Insert Before > New** - Select this action to insert the new topic as a sibling to the current node, before it. This action opens a **New** file dialog box *(on page 3139)* that allows you to select the

type of document and assists you with naming it. After you have configured your new topic, click **Create**.

- **Insert After > New** - Select this action to insert the new topic as a sibling to the current node, after it. This action opens a **New** file dialog box *(on page 3139)* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
- **Duplicate** - Select this action to create a copy of the selected topic and insert it as a sibling. This action opens a dialog box that allows you to choose the file name and location for the newly created copy of the topic. After you have selected the name and path for your new topic, click **OK**.

> **Note:**
> The value of the root ID is generated taking the *Use the file name as the value of the root ID attribute* option from the **DITA > Topics** preferences page *(on page 282)* into account. When the option is deselected, a unique ID is generated.

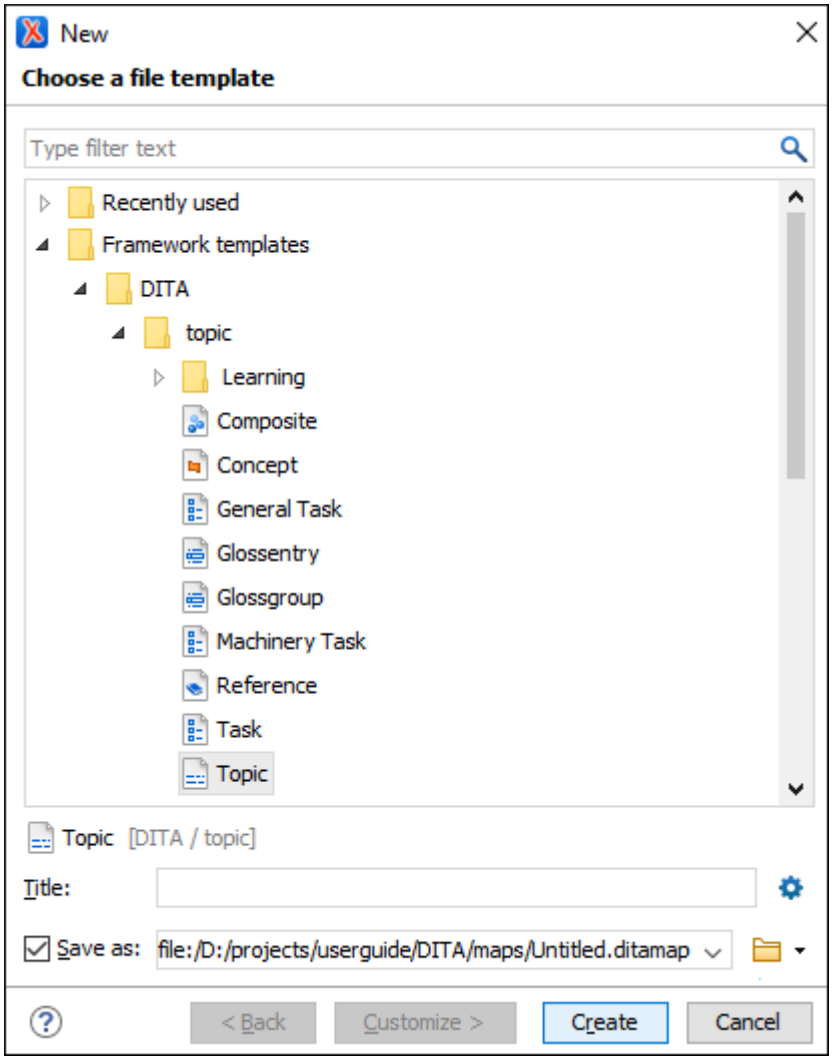
Step Result: The new topic is now referenced (as a `<topicref>`) in the *DITA map* at the location where you inserted it and the new topic is opened in the editor.

3. Save the *DITA map*.

Creating a New DITA Topic Using the New File Wizard

The **New** DITA file dialog box allows you to create a new DITA topic using various types of DITA file templates and provides some options that help you to configure the new topic.

Figure 779. New DITA File Dialog Box



Note:
The templates that appear in this dialog box include all templates that have an associated `.properties` file and the `type` property is set to **dita**, as well as templates that do not have an associated properties file or the `type` property is not defined. It will also include custom templates that you create using the procedures presented in Creating New Document Templates *(on page 385)*.

The **New** DITA file dialog box includes the following features and options:

Choose a file template

Use the template preview pane to select the appropriate type of DITA file you want to create. Once you select a template, the other options will appear below the preview pane.

Tip:
You can use the text filter field at the top of the dialog box to search for a specific template.

Title

Depending on the selected file template, the value of the **Title** field is set in:

- The `<title>` element of a DITA topic file. The `<title>` element needs to be the first child of the root element.
- The `<glossterm>` element of a *Glossentry* file.

New Topics Preferences

Pressing this button opens the DITA New Topics preference page *(on page 282)*.

Save as

Use this option to specify a file name and path for the new file. You can specify the path by using the text field, the history drop-down, or the browsing actions in the **Browse** drop-down menu.

Create

When you click this button, a reference (`<topicref>`) to the new topic is added to the current *DITA map* and the new topic is opened in the editor.

Other Ways to Create a New DITA Topic

In addition to the methods described above, Oxygen XML Editor also provides other ways to create DITA topics, including the following:

- **Fast Create Topics** - You can use the **Fast Create Topics** feature *(on page 3141)* to quickly create multiple skeleton topics at once and you can specify their hierarchical structure within the *DITA map*.
- **Extract Topic From Selection** - When editing a DITA topic in **Author** mode, an **Extract Topic From Selection** action is available in the contextual menu (and the **DITA** menu). It creates a new DITA topic from a selection of content in the current topic.

Related Information:

Getting Started with DITA *(on page 3063)*

Adding Topics to a DITA Map *(on page 3094)*

Working with Markdown Documents in DITA *(on page 3203)*

Fast Create Multiple DITA Topics *(on page 3141)*

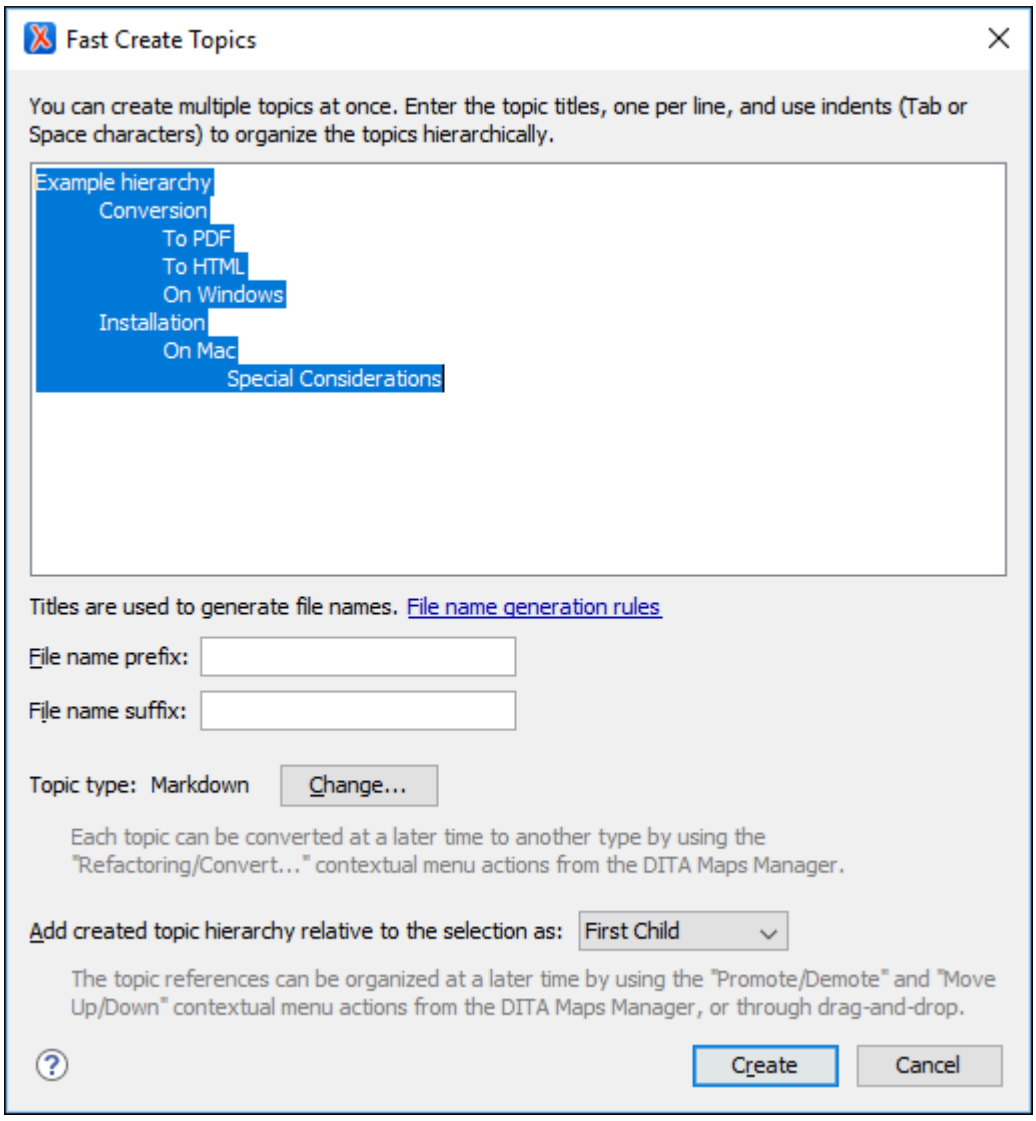
Fast Create Multiple DITA Topics

The **DITA Maps Manager** *(on page 3073)* includes a feature that allows you to quickly create multiple skeleton topics at once and you can specify their hierarchical structure within the *DITA map (on page 3419)*. A common use-case for using this feature is when you need to insert a new chapter or section that will include multiple topics and you have the structure and titles planned out in advance.

Note:
The **Fast Create Topics** feature works for the following types of local and remote resource protocols: *file*, *http*, *https*, *ftp*, *ftps*.

To access this feature, right-click a node in the **DITA Maps Manager** where you want the new topics to be inserted and select **Fast Create Topics**. This opens the **Fast Create Topics** dialog box where you can configure the structure for the new topics.

Figure 780. Fast Create Topics Dialog Box



The **Fast Create Topics** dialog box includes the following features and options:

Hierarchy Text Pane

Use this text area to enter the titles for your new topics, one per line, and specify the hierarchy by using indents (**Tab** or **Space**). Topic references will be created in the *DITA map* according to the hierarchy you enter in this section.

File name generation rules

The titles that you enter in the text pane will not only be used for the topic titles but also to generate their file names and you can click the **File name generation rules** link to configure the rules *(on page 282)* for how those file names will be generated.

> **Tip:**
> If you have added a file name prefix or suffix to the properties file *(on page 388)* for DITA document templates, the generated file name will include that prefix or suffix.

File name prefix

Use this option to add a specified prefix to the file name. If you have added a file name prefix to the properties file *(on page 388)* for DITA document templates, the prefix you enter here will override the one from the properties file.

File name suffix

Use this option to add a specified suffix to the end of the file name. If you have added a file name suffix to the properties file *(on page 388)* for DITA document templates, the suffix you enter here will override the one from the properties file.

Topic type

All of the topics that will be created will have the same DITA topic type, which is detected from the most recently created topic. You can click the **Change** button to select a different type from a list of possible DITA templates.

> **Tip:**
> You can convert any of these new files to a different DITA topic type at a later time by using another feature that allows you to easily convert DITA documents to other types *(on page 3147)*.

Add created topic hierarchy relative to the selection as

By default, the hierarchy of topics will be added to the *DITA map* as the **First Child** of the node where the action was invoked. You can change this to **Last Child**, **Preceding Sibling**, or **Following Sibling** if the selected node allows topics to be inserted as such.

Create

When you click **Create**, the specified hierarchy is added as topic references in the *DITA map*. The new documents are created as bare skeleton topics with only the topic title and possibly the root ID populated.

> **Tip:**
> You can easily change the order of the topics in the *DITA map (on page 3093)* at a later time,

Related Information:
Adding Topics to a DITA Map *(on page 3094)*
Converting DITA Topics to Another Type *(on page 3147)*

Editing DITA Topics

Oxygen XML Editor provides a number of features to help you edit DITA topics. A DITA topic is an XML document, thus all the editing features that Oxygen XML Editor provides for editing XML documents also apply to DITA topics. Oxygen XML Editor also provides extensive additional support specifically for DITA.

Opening a DITA Topic

There are several ways to open a DITA topic in the XML editor. Use any of the following methods to open a topic:

- Double-click the topic in the **DITA Maps Manager** *(on page 3073)* (or right-click the topic and select **Open**).
- Double-click the file in the **Project** view *(on page 413)* (or right-click the file and select **Open**).
- If you have a *DITA map (on page 3419)* opened in the XML editor, you can click the  icon to the left of the topic.
- Drag a DITA file from your system browser and drop it in the XML editor.

Visual Editing in Author Mode

DITA is an XML format *(on page 34)*, although you do not have to write raw XML to create and edit DITA topics. Oxygen XML Editor provides a graphical view of your topics in **Author** mode *(on page 363)*. Your topics will likely open in **Author** mode by default, so this is the first view you will see when you open or edit a DITA topic. If your topic does not open in **Author** mode, just click **Author** at the bottom left of the editor window to switch to this mode.

Author mode presents a graphical view of the document you are editing, similar to the view you would see in a word processor. However, there are some differences, including:

- **Author** mode is not a **WYSIWYG** view. It does not show you exactly what your content will look like when printed or displayed on-screen. The appearance of your output is determined by the DITA publishing process, and your organization may have modified that process to change how the output is displayed. Oxygen XML Editor has no way of determining what your final output will look like or where line breaks or page breaks will fall. Treat **Author** mode as a friendly visual editing environment, not a faithful preview of your output.
- Your document is still an XML document. **Author** mode creates a visual representation of your document by applying a CSS stylesheet to the XML. You can see the XML at any time by switching to **Text** mode *(on page 362)*. You, or someone in your organization, can change how the **Author** view looks by changing the CSS stylesheet or providing an alternate stylesheet.

- Your aim in editing a DITA document is not to make it look right, but to create a complete and correct DITA XML document. **Author** mode keeps you informed of the correctness of your content by highlighting XML errors in the text and showing you the current status in a box at the top right of the editor window. Green means that your document is valid, yellow means valid with warnings, and red means invalid. Warnings and errors are displayed when you place the cursor on the error location.
- Your XML elements may have attributes set on them. Conventionally, attributes are used to contain metadata that is not displayed to the reader. By default, attributes are not displayed in the **Author** view (though there are some exceptions) and cannot be edited directly in the **Author** view (though in some cases the CSS that drives the display may use form controls to let you edit attributes directly). To edit the attributes of an element, place your cursor on the element and press **Alt+Enter** to bring up the attribute editor. Alternatively, you can use the **Attributes** view *(on page 638)* to edit attributes.

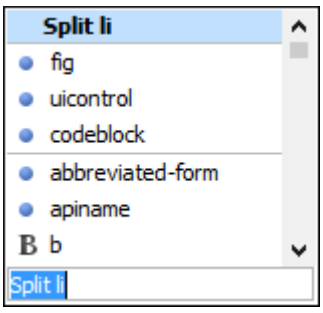
Tip:
You can select **Hints** from the **Styles** drop-down menu (available on the **Author Styles** toolbar) to display tooltips throughout the DITA document that offers additional information to help you with the DITA structure. For more information, see the Selecting and Combining Multiple CSS Styles *(on page 2262)* section.

Content Completion Assistance

Since it is a structured format, DITA only allows certain elements in certain places. The set of elements allowed differs from one DITA topic type to another (this is what makes one topic type different from another). To help you figure out which elements you can add in any given place and help you understand what they mean, Oxygen XML Editor has a number of *Content Completion Assistant (on page 3418)* features.

- **The Enter key:** In **Author** mode, the **Enter** key does not create line breaks, it brings up the *Content Completion Assistant* to help you enter a new element. In XML, you do not use line breaks to separate paragraphs. You create paragraphs by creating paragraph elements (element `<p>` in DITA) and tools insert the line breaks in the output and on-screen.

Figure 781. Content Completion Assistant



The *Content Completion Assistant* not only suggests new elements you can add. If you press **Enter** at the end of a *block element (on page 3417)* (such as a paragraph) it suggests creating a new element of the same type. If you press **Enter** in the middle of a *block element*, it suggests splitting that element into two elements.

A useful consequence of this behavior is that you can create a new paragraph simply by hitting **Enter** twice (just as you might in a text editor).

As you highlight an element name, a basic description of the element is displayed. Select the desired element and press **Enter** to create it.

To wrap an element around an existing element or piece of text, simply select it and press **Enter** and use the *Content Completion Assistant* to choose the wrapper element.

- **The Model view:** You can see the entire model of the current element by opening the **Model** view *(on page 555)* (**Window > Show View > Model**, if the view is not already open). The **Model** view shows you what type of content the current element can contain, all the child elements it can contain, all its permitted attributes, and their types.

Tip:
You can also select **Inline actions** from the **Styles** drop-down menu (available on the **Author Styles** toolbar) to display possible elements that are allowed to be inserted at various locations throughout the DITA document. For more information, see the Selecting and Combining Multiple CSS Styles *(on page 2262)* section.

DITA Editing Actions

A variety of actions are available in the DITA *framework (on page 3420)* to specifically assist you with editing DITA documents. These various actions are available in the contextual menu, the **DITA** menu, the **DITA (Author Custom Actions)** toolbar, or the *Content Completion Assistant*.

The **DITA** toolbar contains buttons for inserting a number of common DITA elements (elements that are found in most DITA topic types).

If the **DITA** toolbar is not displayed, right-click anywhere on the toolbar area, select **Configure Toolbars**, and select it from the displayed dialog box.

Note:
The **DITA** toolbar contains a list of the most common elements and actions for DITA, such as inserting an image, creating a link, inserting a content reference, or creating a table. It does not contain a button for inserting every possible DITA element. For a complete list of elements that you can insert at the current location in your document, press **Enter** to open the *Content Completion Assistant*.

Whenever the current document in the editor is a DITA document, the **DITA** menu is displayed in the menu bar. It contains a large number of actions for inserting elements, creating content references and keys, editing DITA documents, and controlling the display. These actions are specific to DITA and supplement the general

editing commands available for all document types. Many of these actions are also conveniently available in the contextual menu. In addition to the DITA *framework*-specific actions *(on page 3180)*, the contextual menu also includes various *general* **Author** mode contextual menu actions *(on page 771)*.

Related Information:
Getting Started with DITA *(on page 3063)*
DITA Topic Author Mode Actions *(on page 3180)*

Converting DITA Topics to Another Type

Oxygen XML Editor includes a feature that allows you to convert an existing DITA document to a different topic type. For example, if you want to convert a DITA Task to a DITA Topic, or vice versa. There are several ways to access these refactoring actions and you can choose a scope for the operation and some filtering options.

DITA Conversion Refactoring Operations for *DITA*

The following conversion operations are available:

Convert Nested Topics to New Topics (Available from the contextual menu of editable maps/nodes in the DITA Maps Manager *(on page 3073)*)

Use this operation on topics that contain nested `<topic>` elements to convert each nested topic to a new topic. Also, the new topics are added in the **DITA Maps Manager** as the first child topics of the original topic.

Convert Sections to New Topics (Available from the contextual menu of editable maps/nodes in the DITA Maps Manager *(on page 3073)*)

Use this operation on topics that contain multiple sections to convert each section to a new topic. Also, the new topics are added in the **DITA Maps Manager** as the first child topics of the original topic.

Note:
As long as the DITA topic is of the type *topic*, *concept*, or *reference*, the new topics that will be created from the inner sections will retain the same topic type as the original topic.

Convert to Concept

Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept).

Convert to General Task

Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). A DITA *General Task* is a less restrictive alternative to the *Strict Task* information type.

Convert to Reference

Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference).

Convert to Task

Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task).

Convert to Topic

Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic).

Convert to Troubleshooting

Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting).

Methods for Accessing the DITA Conversion Refactoring Operations

To access the conversion operations, use one of the following methods:

Single Document Method

With the document opened in the editor, right-click anywhere in the main editing pane (or right-click the topic reference in the **DITA Maps Manager** *(on page 3073)*), go to the **Refactoring** submenu, and choose whichever operation is appropriate for your needs.

Multiple Documents At Once Method

Select **XML Refactoring** from the **Tools** menu (or from the **Refactoring** submenu when you right-click one or more documents in the **Project** view *(on page 413)*or the **DITA Maps Manager** view *(on page 3073)*). Then select whichever operation is appropriate for your needs.

XML Refactoring Wizard Dialog Box

When you select any of the operations, Oxygen XML Editor proceeds to the **XML Refactoring Wizard**. If you used the **Multiple Documents At Once Method** *(on page 3148)*, the wizard page allows you to choose a scope for the operation and some filtering options:

- **Scope** - Select from a variety of options to define the scope that will have resources affected by the operation. For example, you can choose to affect all resources in the **Project**, **All opened files**, **Current DITA map hierarchy**, **Selected reference**, and others depending on the context.
- **Filters** section
  - **Include files** - Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as ***** or **?**).
  - **Restrict to known XML file types only** - Excludes non-XML file types from the operation.
  - **Look inside archives** - If this option is selected, the scope of the operation will include files inside archives.

If you used the **Single Document Method** *(on page 3148)*, the scope will be the current file so the scope and filtering options are not displayed.

You can then use one of the following buttons to proceed with the operation:

Preview

You can use the **Preview** button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

> **Warning:**
> It is always recommended to use the **Preview** button to make sure the operation is not going to do something unexpected and after you click the **Finish** button, any **Undo** action will only revert changes on the current document.

Finish

When you use the **Finish** button, behind the scenes Oxygen XML Editor maps the structure of the previous DITA document type to a structure that fits the new type. In some cases, especially when the previous structure was very complex, the conversion might result in an invalid structure and some manual adjustments might be required.

Handling Special Characters When Generating New File Names

For refactoring operations that generate a new file, if special characters are detected in an element that will be used to generate the new file name, the special characters will automatically be replaced with their ASCII equivalents (for example, **Ä** is changed to **AE**). If an ASCII equivalent does not exist, it will be replaced with an underline character (_). The purpose of this functionality is to avoid generating invalid file names.

It is possible to customize the list of replaceable symbols by editing the following XSLT character map file:

`[OXYGEN_INSTALL_DIR]/frameworks/dita/refactoring/utils/character-map.xsl`.

Converting To and From DITA Specialization Document Types

If you use your own DITA specialization document type *(on page 3363)*, you can modify mappings for the predefined conversion operations to work with your specialization.

To use the conversion operations with your DITA specialization, follow these steps:

1. Locate the conversion stylesheets in the following directory (and its subdirectories): `[OXYGEN_INSTALL_DIR]/frameworks/dita/refactoring/`.

   > **Note:**
   > The stylesheets for converting entire files (from one type to another) are located in the `dita-files-conversion-stylesheets` folder. Each of these conversion operations has a stylesheet with the word **entrypoint** at the end of its name. Edit the appropriate `*-`

`entrypoint.xsl` file (for example, to modify the **Convert to Task** operation, edit the `convert-resource-to-task-entrypoint.xsl` file).

2. Depending on whether you use a DTD, XML Schema, or Relax NG-based specialization, you can:
    a. Modify the values of the declared **root-element**, **public-literal-target**, and **system-literal-target** variables to match your specialization's DTD information.
    b. Modify the value of the declared **schema-location** variable to match the location of your specialization's XML schema.
    c. Modify the value of the declared **xml-model-location** variable to match your Relax NG specialization.
3. For the **Convert Nested Topics to New Topics** and **Convert Sections to New Topics** operations, if your DITA specialization uses your own custom URN or DOCTYPE, you can replace the default mappings in the *`[OXYGEN_INSTALL_DIR]`*`/frameworks/dita/refactoring/utils/dita-formats.xsl` stylesheet with your own values for the `DOCTYPE` or `xml-model`.
4. If you want to change the name of the operation that will be displayed in Oxygen XML Editor, follow these substeps:
    a. Locate the resource XML file for the same conversion operation in the following directory: *`[OXYGEN_INSTALL_DIR]`*`/frameworks/dita/refactoring/` (for example, for the **Convert to Task** operation, it is `convertResource2Task.xml`).
    b. Edit that XML file and change the **name** attribute to match whatever you want to be displayed for that operation (for example, `name="Convert to My DocType"`).
5. Save your changes to all modified files.
6. Restart Oxygen XML Editor

Result: You should now see your changes when accessing the conversion operations *(on page 3148)*.

Tip:
You can also create your own customized refactoring operations. For more information, see Custom Refactoring Operations *(on page 868)*.

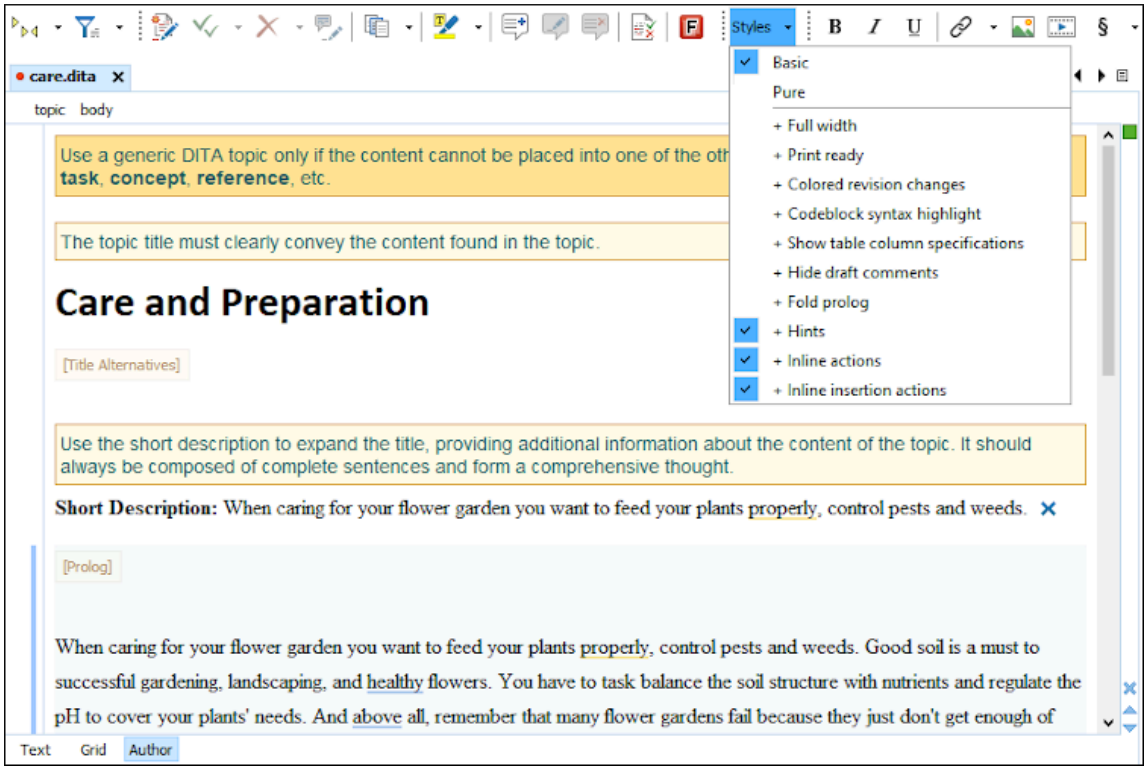
Changing the Look of DITA Documents in Author Mode Using the Styles Menu

The **Author** mode renders the content of the DITA documents visually, based on CSS stylesheets associated with the document.

Oxygen XML Editor provides a **Styles** drop-down menu on the toolbar that allows you to select one *main (non-alternate) CSS style (on page 3421)* and multiple *alternate CSS styles (on page 3417)*. This makes it easy to change the look of the document as it appears in **Author** mode.

Figure 782. Styles Drop-down Menu in a DITA Document



You can use the **Styles** drop-down menu to select a *main css style (on page 3421)* that applies to the whole document and then select one or more *alternate css styles (on page 3417)* that behave like layers and are merged sequentially with the *main style*. Each of the styles that are listed in this drop-down menu have a corresponding CSS file that defines how your documents are rendered in **Author** mode and in the output. Also, the selections from this drop-down menu are persistent, meaning that Oxygen XML Editor remembers them when subsequent documents are opened.

Unique CSS Styles for DITA

Oxygen XML Editor comes with a set of built-in CSS layer stylesheets for DITA documents (as well as some that are specifically for *DITA maps (on page 3419)*).

Some of these unique alternate styles for DITA documents include:

- **Hints** - Displays tooltips throughout DITA documents that offer additional information to help you with the DITA structure.
- **Inline actions** - Displays possible elements that are allowed to be inserted at various locations throughout DITA documents.
- **Inline insertion actions** - Displays a widget (⊕) near each empty paragraph that makes it easy to insert DITA elements (for example, to insert lists, notes, or tables).

Tip:
For information about configuring the **Styles** drop-down menu, see Configuring and Managing Multiple CSS Styles for a Framework *(on page 2262)*.

Working with Images in DITA Topics

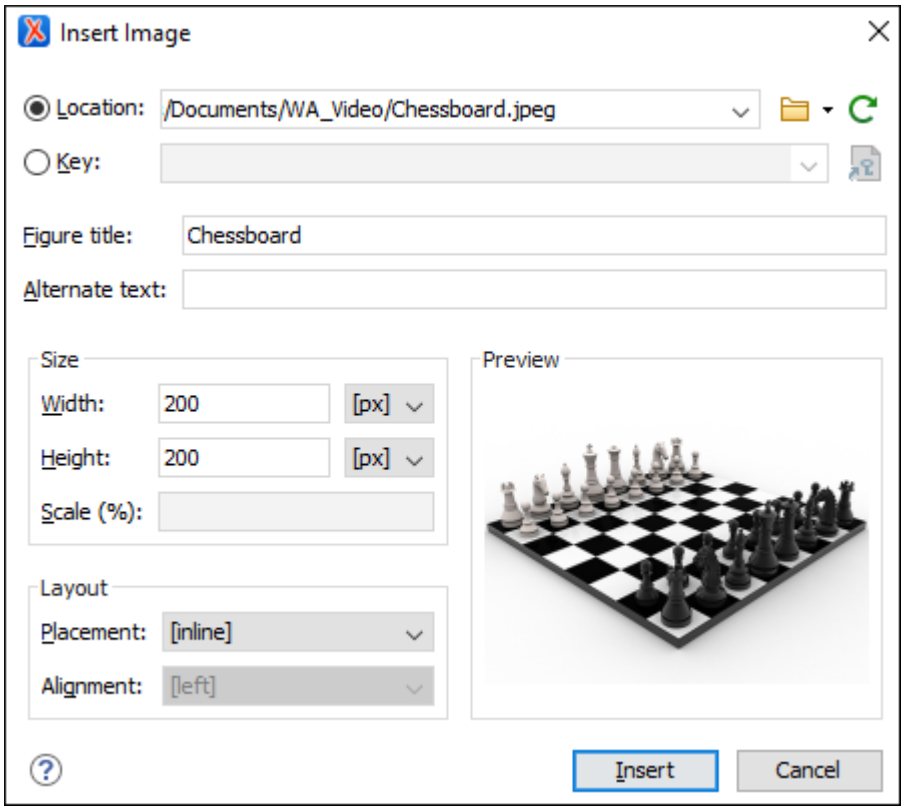
There are several ways to add images to a DITA topic, depending on if you want to create a figure element (with a title and caption), just insert an image inline, or if you want to use multiple versions of a graphic depending on the situation. For instance, you might want to use a specific image for each different product version or output media.

Adding an Image Inline with the Insert Image Dialog Box

Use the following procedure to add an image inline:

1. Place the cursor in the position you want the graphic to be inserted.
2. Select the **Insert Image** action. The **Insert Image** dialog box appears.

Figure 783. Insert Image Dialog Box



3. Configure the options in this dialog box and click **Insert**.

The **Insert Image** dialog box includes the following options and features for inserting images into a DITA document:

Location

Use this option to specify a URL for the image as the value of an `@href` attribute inside the `<image>` element. You can type the URL of the image you want to insert or use browsing actions in the **Browse** drop-down menu (there is also a history drop-down).

Key

Use this option to insert the selected key as the value of a `@keyref` attribute inside the `<image>` element. All keys that are presented in the dialog box are gathered from the *root map (on page 3424)* of the current *DITA map*. You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that presents the list of keys available in the selected *root map*.

> **Note:**
> If your defined keys are not listed in this dialog box, it is most likely trying to gather keys from the wrong *root map*. You can change the *root map* by using the **Change Root Map** link in the **Choose Key** dialog box or change it in the **Context** option in the toolbar of the **DITA Maps Manager**.

Figure title

Use this text box to insert a `<title>` and `<image>` element inside a `<fig>`.

Alternate text

Use this text box to insert an `<alt>` element inside the `<image>`.

Size

Use this section to configure the **Width** and **Height** of the image, or **Scale** the image. Specifying a value in these options inserts a `@width`, `@height`, and `@scale` attribute, respectively.

Layout

Use the options in this section to insert `@placement` and `@align` attributes into the `<image>` element.

Preview

The **Preview** box shows a thumbnail of the selected image so that you can see a preview of the image before clicking **Insert**.

Adding an Image Inline with Drag/Drop (or Copy/Paste) Actions

You can drag images from your system explorer or the **Project** view *(on page 413)* and drop them into a DITA document (or copy and paste). This will insert the path of the image file as the value of the `@href` attribute in a DITA `<image>` element:

```
<image href="../images/image_file.png"/>
```

> **Tip:**
> To replace an image, just drag and drop a new image over the existing one. Oxygen XML Editor will automatically update the reference to the new image.

Adding an Image in a Figure Element

To add an image in a figure:

1. Add a `<fig>` element to your document at the appropriate place.
2. Add a `<title>` and/or `<desc>` element to `<fig>`, according to your needs.
3. Add an `<image>` element *(on page 3152)* to the `<fig>` element.

Note:
The `<fig>` element has a number of other child elements that may be appropriate to your content. See the DITA documentation for complete information about `<fig>`.

Note:
The order that the content of the `<image>`, `<title>`, and `<desc>` elements will appear in the output is determined by the output transformation. If you want to change how they appear, you may have to modify the output transformation, rather than your source content.

Floating Images in DITA Topics for PDF or XHTML Output

Oxygen XML Editor provides the possibility of floating an image to the left or right of blocks of content in DITA topics, for both PDF and XHTML output.

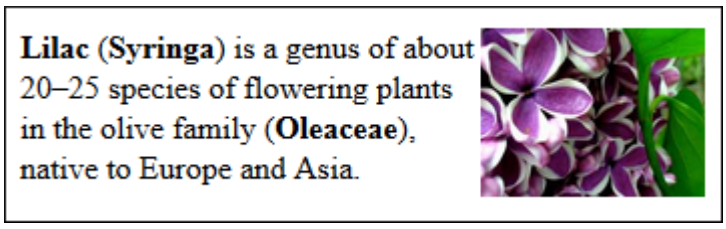
To float an image, you simply need to set the `@outputclass` attribute on the `<image>` element. The possible values are:

- **float-left**
- **float-right**

For example, the following DITA structure will present the image to the right of the paragraph content in the output:

```
<p><image href="../../images/Lilac.jpg" scale="45" outputclass="float-right"/>
  <b>Lilac</b> (<b>Syringa</b>) is a genus of about 20–25 species of flowering plants
  in the olive family (<b>Oleaceae</b>), native to Europe and Asia.
</p>
```

Figure 784. Image Floated to the Right



Searching for References to Images

You can search for all references to an image by selecting **Search References** from the contextual menu. The result depends on how the image is defined, as follows:

- If the action is invoked on an `<image>` element that contains an `@href` attribute but does not include an `@id` attribute, all direct references to the image are reported. If the `<image>` element does have an `@id` attribute, all links to the specified *ID* are also reported.
- If the action is invoked on an `<image>` element that contains a `@keyref` attribute but does not include an `@id` attribute, all direct references to the image are reported along with all instances where the key is used. If the `<image>` element does have an `@id` attribute, all links to the specified *ID* are also reported.

Short Video Clip: Learn DITA Editing with Oxygen - Various Ways to Insert Image References

Adding Video, Audio, and Embedded HTML Resources in DITA Topics

You can insert references to media resources (such as videos, audio clips, or embedded HTML frames) in your DITA topics. The media resources can be played directly in **Author** mode and in all HTML5-based outputs. There is a toolbar button ( ) that allows you to insert and configure a reference to the media resource. You can also drag media files from your system explorer or the **Project** view *(on page 413)* and drop them into your documents (or copy and paste them).

Table 54. Supported Media Types

Media	Description	Type	Supported Size Properties
mp3	Moving Picture Experts Group Layer-3 Audio	audio	Width
wav	Windows Wave	audio	Width
pcm	Pulse Code Modulation	audio	Width
m4a	Moving Picture Experts Group Layer-4 Audio	audio	Width
aif	Audio Interchange Format	audio	Width
mp4	Moving Picture Experts Group Layer-4 Video	video	Width & Height

Table 54. Supported Media Types (continued)

Media	Description	Type	Supported Size Properties
m4v	Itunes Video File	video	Width & Height
avi	Audio Video Inter-leaved	video	Width & Height
embedded video (such as *YouTube*, *Vimeo*, or *Vidyard*)	Embedded Iframe Code	iframe	Width & Height

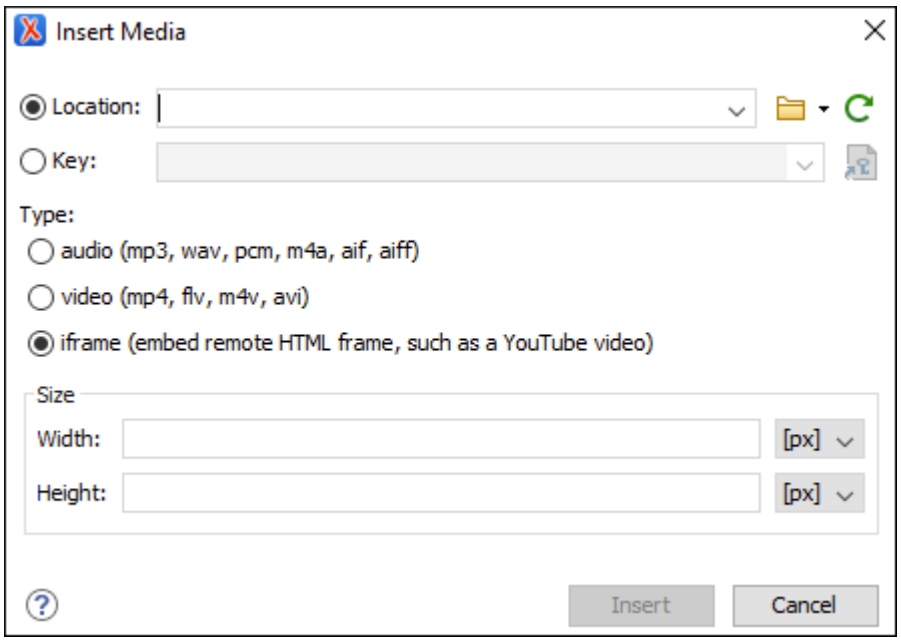
Adding a Media Resource

To insert a media resource in a DITA document, use the following procedure:

1. Place the cursor at the location where you want the media resource.
2. Select the **Insert Media Resource** action from the toolbar. The **Insert Media** dialog box appears.

> **Note:**
> You can also drag media files from your system explorer or the **Project** view *(on page 413)* and drop them into your documents (or copy and paste them). Note that this method will bypass the **Insert Media** dialog box, so if you need to adjust the size you will need to adjust the `@width` or `@height` attributes manually.

Figure 785. Insert Media Dialog Box



3. Configure the options in this dialog box and click **Insert**.

   The **Insert Media** dialog box includes the following options:

Location

Use this option to specify a URL for the media resource as the value of a `@data` attribute inside the `<object>` element. You can type the URL of the resource you want to insert or use browsing actions in the **Browse** drop-down menu (there is also a history drop-down).

Key

Use this option to insert the selected key as the value of a `@datakeyref` attribute inside the `<object>` element. All keys that are presented in the dialog box are gathered from the *root map (on page 3424)* of the current *DITA map*. You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that presents the list of keys available in the selected *root map*.

> **Note:**
> If your defined keys are not listed in this dialog box, it is most likely trying to gather keys from the wrong *root map*. You can change the *root map* by using the **Change Root Map** link in the **Choose Key** dialog box or change it in the **Context** option in the toolbar of the **DITA Maps Manager**.

Type

Oxygen XML Editor detects and automatically selects the media type based upon the specified resource in the URL field *(on page 3157)*. You can manually change the type, but keep in mind that in the publishing stage the *object* element is converted to an HTML5 element *(on page 3157)* based upon the type selected here. You can choose between: **audio**, **video**, or **iframe**.

Size

Use this section to configure the **Width** and **Height** of the frame for the media resource. Specifying a value in these options inserts a `@width` and `@height` attribute, respectively. For audio clips, only the **Width** can be adjusted.

Result in Author Mode: A reference to the specified video, audio, or embedded HTML frame is inserted in an `<object>` element and it is rendered in **Author** mode so that it can be played directly from there.

> **Attention:**
>
> - On Ubuntu 17.10, if you receive an error when trying to play videos in **Author** mode, you need to install the `libavformat57` library.

Result in Output: In the publishing stage, the `<object>` element is converted to an HTML5 element so that it can be rendered properly and played in all HTML5-based outputs.

- **Videos** - The `<object>` element is converted to an HTML5 `<video>` element.
- **Audio Clips** - The `<object>` element is converted to an HTML5 `<audio>` element.
- **Embedded HTML Frames** - The `<object>` element is converted to an HTML5 `<iframe>` element.

Tip:
There is an even faster way of inserting an embedded video (such as a YouTube, Vimeo, or Vidyard). If you copy the embed code from the source (for example, you can right-click on a YouTube video and select **Copy embed code**), you can then paste the contents of the clipboard in the **URL** field *(on page 3157)* and the **Type** *(on page 3157)* will automatically be set on **iframe**, while the **Width** and **Height** *(on page 3157)* will be populated according to the detected size, and an `allowfullscreen` parameter will automatically be added (set the value of this parameter to **true** to allow videos to play in full screen mode once the document is converted to XHTML output).

Inserting Media in HTML Outputs That Do Not Support Embedded Media

For certain types of HTML output (for example, CHM) that do not support embedded media (such as videos or audio files), Oxygen XML Editor provides a parameter that can be set in the transformation scenario to present the media object as a plain link in the output.

This can be achieved by following these steps:

1. Edit the DITA transformation scenario *(on page 3291)* for the output type that does not support embedded objects (for example, **DITA Map CHM**).
2. Go to the **Parameters** tab *(on page 3297)* and click the **New** button to add a new parameter.
3. For the **Name**, enter: **com.oxygenxml.xhtml.linkToMediaResources**.
4. For the **Value**, enter: **true**.
5. Click **OK** and run the transformation.

Result: The media object will appear in the output as a plain link instead of an embedded object.

Working with Image Maps in DITA

Oxygen XML Editor includes support for **image maps** in DITA documents through the use of the `<imagemap>` element. This feature provides an easy way to create hyperlinks in various areas within an image without

having to divide the image into separate image files. The visual **Author** editing mode includes an **Image Map Editor** that helps you to easily create and configure image maps.

Figure 786. Image Map Editor in DITA

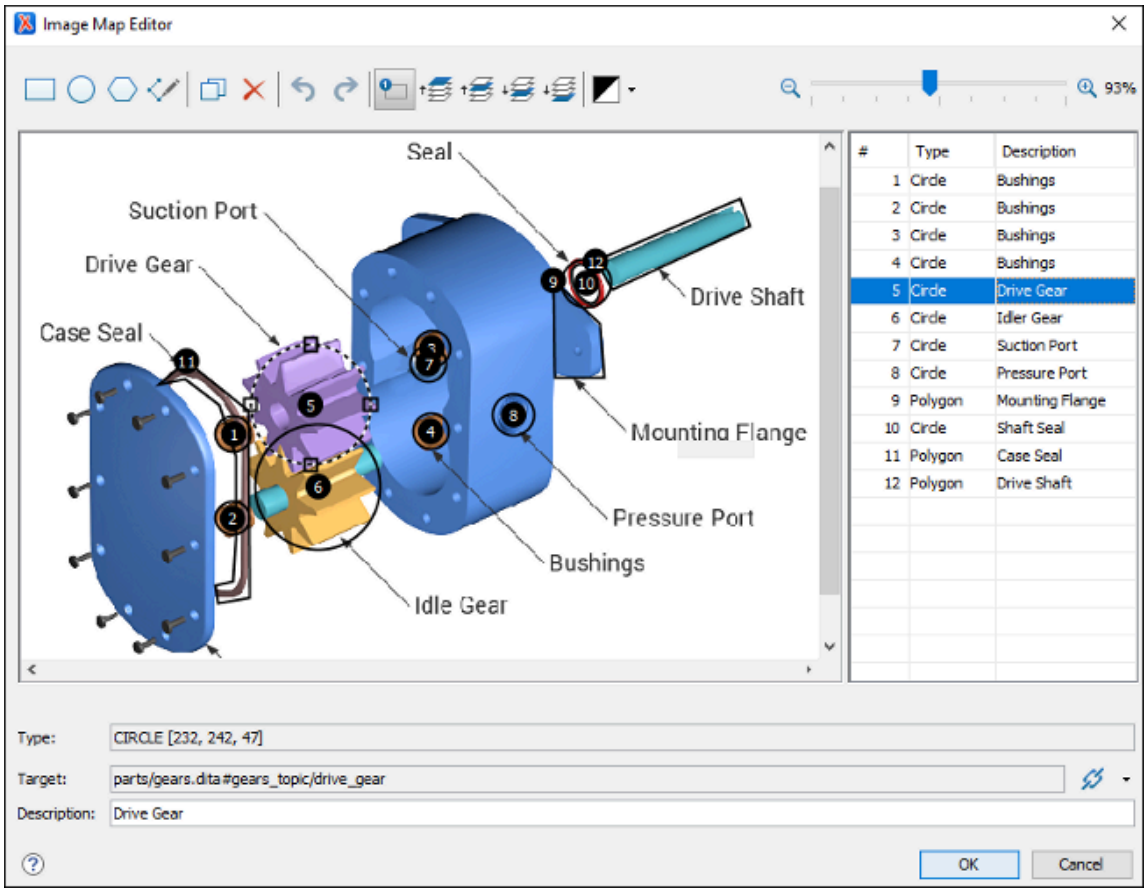

Image Map Editor Interface in DITA

The interface of the **Image Map Editor** consists of the following sections and actions:

Toolbar

New Rectangle

Use this button to draw a rectangular shape over an area in the image. You can drag any of the four points to adjust the size and shape of the rectangle.

New Circle

Use this button to draw a circle over an area in the image. You can drag any of the four points to adjust the size of the circle.

New Polygon

Use this button to draw a polygon shape over an area in the image. This action opens a dialog box that allows you to select the number of points for the polygon. You can drag any of the points to adjust the size and shape of the polygon.

New Free Form Shape

Use this button to draw a free form shape over an area in the image. After selecting this button, left-click anywhere in the image to place the first point of your shape. Then move the cursor to the location of the next desired point and left-click to place the next point, and so on. To complete the shape (area), click the first point again and a line will automatically be added from the last point that was added, or simply double-click the last point to automatically add the line from the last point back to the first.

Duplicate

Use this button to create a duplicate of the currently selected shape.

Delete

Use this button to delete the currently selected shape.

Undo

Use this button to undo the last action.

Redo

Use this button to redo the last action that was undone.

Show/Hide Numbers

Use this button to toggle between showing or hiding the numbers for the shapes.

Bring Shape to Front

Use this button to bring the currently selected shape forward to the top layer.

Bring Shape Forward

Use this button to bring the currently selected shape forward one layer.

Send Shape Backward

Use this button to send the currently selected shape back one layer.

Send Shape to Back

Use this button to send the currently selected shape back to the bottom layer.

Color Chooser

Use this drop-down menu to select a color scheme for the lines and numbers of the shapes.

Zoom Slider

Use this slider to zoom the image in or out in the main image pane.

Image Pane

This main Image Pane is where you work with shapes to add hyperlinks to multiple areas within an image. The editing mechanisms that are supported in the Image Pane include the following:

Mouse Controls and Keyboard Shortcuts

- Use the mouse to select and move shapes around in the image pane. It is easy to see which shape is selected in this image pane because the border of the selected shape changes from a solid line to a dotted one.
- You can also drag any of the points of a selected shape to adjust its size and shape.
- You can hold down the **Ctrl** key to select multiple shapes and then move them simultaneously.
- You can also move shapes by using the arrow keys on your keyboard. In addition, you can hold down **Shift** while using the arrow keys to move the shape further or **Alt** to move it 1 pixel at a time.
- To zoom in or out, you can use the **NumPad +** or **NumPad -** keys respectively. Use **Ctrl + NumPad 0** to reset the zoom level to its default value.
- You can use **Ctrl + Z** to undo an action or **Ctrl + Y** to redo the last action that was undone.

Contextual Menu Actions Available in the Image Pane

You can right-click the shapes, points, or anywhere in the Image Pane to invoke the contextual menu where the following actions are available:

Add Point

Adds a point to *Polygon* or *Free Form* shapes.

Remove Point

Removes the current point from *Polygon* or *Free Form* shapes.

Duplicate

Create a duplicate of the currently selected shape.

Delete

Delete the currently selected shape.

New Rectangle

Creates a rectangular shape over an area in the image. You can drag any of the four points to adjust the size and shape of the rectangle.

New Circle

Creates a circle over an area in the image. You can drag any of the four points to adjust the size of the circle.

New Polygon

Creates a polygon shape over an area in the image. This action opens a dialog box that allows you to select the number of points for the polygon. You can drag any of the points to adjust the size and shape of the polygon.

Undo

Use this action to undo the last action.

Redo

Use this action to redo the last action that was undone.

Shape Table

The table at the right of the *Image Pane* is a sequential list of all the areas (shapes) that have been added in the image. It shows their number, type, and description (if one has been added). If you select one of the entries in the table, the corresponding shape will be selected in the *Image Pane*.

Properties

Type

Displays information about the selected coordinate.

Target

Allows you to choose the target resource that you want the selected area (shape) to be linked to. Select a target by using the **Link** drop-down menu to the right of the text field. You can choose between the following types of links: **Cross Reference**, **File Reference**, or **Web Link**. All three types will open a dialog box that allows you to define the target resource. This linking process is similar to the normal process of inserting links in DITA *(on page 3255)* by using the identical **Link** drop-down menu from the main toolbar.

When you click **OK** to finalize your changes in the **Image Map Editor**, an `<xref>` element will be inserted with either an `@href` attribute or a `@keyref` attribute. Additional attributes may also be inserted and their values depend on the target and the type of link. For details about the three types of links and their dialog boxes, see Inserting a Link in Oxygen XML Editor *(on page 3255)*.

Description

You can enter an optional description for the selected area (shape) that will be displayed in the **Image Map Details** section *(on page 3163)* in **Author** mode and as a tooltip message when the end-user hovers over the hyperlink in the output.

How to Create an Image Map in DITA

To create an image map on an existing image in a DITA document, follow these steps:

1. Right-click the image and select **Image Map Editor**.

   Step Result: This action will apply an *image map* to the current image and open the **Image Map Editor** dialog box.

2. Add hyperlinks to the image by selecting one of the shape buttons (**New Rectangle**, **New Circle**, or **New Polygon**).
3. Move the shape to the desired area in the image and drag any of the points on the shape to adjust its size or form. You can use the other buttons on the toolbar *(on page 3159)* to adjust its layer and color, or to perform other editing actions.

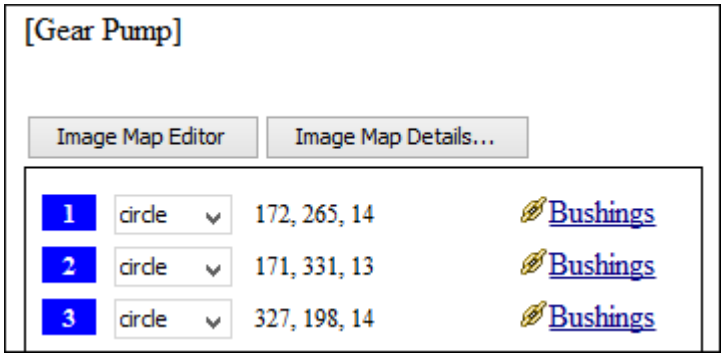
   > **Tip:**
   > You can right-click any of the points, shapes, or anywhere in the Image Pane to access various helpful contextual menu actions *(on page 3161)*. For example, the easiest way to remove a point is to right-click the point and select **Remove Point**.

4. With the shape selected, use one of the linking options *(on page 3162)* in the **Link** drop-down menu to select a target resource (or enter its path in the **Target** *(on page 3162)* text field).
5. (Optional) Enter a **Description** *(on page 3162)* for the selected area (shape).
6. If you want to add more hyperlinks to the image, select a shape button again and repeat the appropriate steps.
7. When you are finished creating hyperlinks, click **OK** to process your changes.

Result: The *image map* is applied on the image and the appropriate elements and attributes are automatically added. In **Author** mode, the image map is now rendered over the image. If the image includes an `<alt>` element, its value will be displayed under the image. The following two buttons will also now be available under the image in **Author** mode:

- **Image Map Editor** - Click this button to open the **Image Map Editor**.
- **Image Map Details** - Click this button to expand a section that displays the details of the image map and allows you to change the shape and coordinates of the hyperlinked areas. Keep in mind that if you change the shape in this section, you also need to add or remove coordinates to match the requirements of the new shape.

Figure 787. Image Map Details



How to Edit an Existing Image Map in DITA

To edit an existing image map, use any of the following methods:

- Simply double-click the image.
- Right-click the image and select **Image Map Editor**.
- Click the **Image Map Editor** button below the image.

All three methods open the **Image Map Editor** where you can make changes to the image map using the various features described above. You can also make changes to the XML structure of the image map in the **Text** editing mode.

You can also click the **Image Map Details** button below the image to expand a section that displays the details of the image map and allows you to change the shape and coordinates of the hyperlinked areas. Keep in mind that if you change the shape in this section, you also need to add or remove coordinates to match the requirements of the new shape.

Overlapping Areas

If shapes overlap one another in the **Image Map Editor**, the one on the top layer takes precedence. The number shown inside each shape represents its layer (if the numbers are not displayed, click the **Show/Hide Numbers** button on the **Image Map Editor** toolbar *(on page 3159)*). To change the layer order for a shape, use the layer buttons on the **Image Map Editor** toolbar *(on page 3159)* (, , ,).

If you insert a shape and all of its coordinates are completely inside another shape, the **Image Map Editor** will display a warning to let you know that the shape is entirely covered by a bigger shape. Keep in mind that if a shape is completely inside another shape, its hyperlink will only be accessible if its layer is on top of the bigger shape.

Related Information:

DITA '*imagemap*' Element Specifications

Working with Images in DITA Topics *(on page 3152)*

Adding Tables in DITA Topics

You can use the **Insert Table** action on the toolbar or from the contextual menu to add a table in a DITA topic. By default, DITA supports four types of tables:

- DITA *Simple* table model *(on page 3165)* - This is the most commonly used model for basic tables.
- CALS table model (OASIS Exchange Table Model) *(on page 3167)* - This is used for more advanced functionality.
- DITA *Choice* table model *(on page 3169)* - This is used within a `<step>` element in a DITA Task document to describe a series of optional choices that a user must make before proceeding.
- DITA *Properties* table model *(on page 3171)* - This is used in DITA Reference documents to describe a property (for example, its type, value, and description).

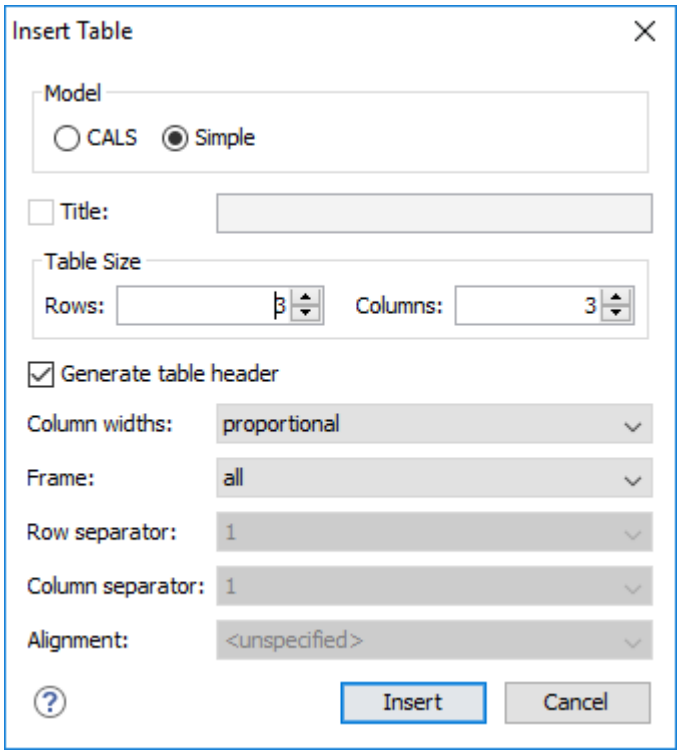
If you are using a specialized DITA vocabulary, it may contain specialized versions of these table models.

Since DITA is a structured format, you can only insert a table in places in the structure of a topic where tables are allowed. The Oxygen XML Editor toolbar provides support for entering and editing tables. It also helps to indicate where you are allowed to insert a table or its components by disabling the appropriate buttons.

Inserting a Simple Table Model

To insert a **Simple** DITA table, select the **Insert Table** action on the toolbar or from the contextual menu (or the **Table** submenu from the **DITA** menu). The **Insert Table** dialog box appears. Select **Simple** for the table **Model**.

Figure 788. Insert Table Dialog Box - Simple Model



The dialog box allows you to configure the following options when you select the **Simple** table model:

Title

If this checkbox is selected, you can specify a title for your table in the adjacent text box.

Generate table header

If selected, an extra row will be inserted at the top of the table to be used as the table header.

Column widths

Allows you to specify the type of properties for column widths (`@colwidth` attribute). You can choose one of the following properties for the column width:

- **proportional** - The width is specified in proportional (relative) units of measure. The proportion of the column is specified in a `@relcolwidth` attribute with the values listed as the number of shares followed by an asterisk. The value of the shares is totaled and rendered as a percent. For example, `relcolwidth="1* 2* 3*"` causes widths of 16.7%, 33.3%, and 66.7%. When entering content into a cell in one column, the width proportions of the other columns are maintained. If you change the width by dragging a column in **Author** mode, the values of the `@relcolwidth` attribute are automatically changed accordingly. By default, when you insert, drag and drop, or copy/paste a column, the value of the `@relcolwidth` attribute is `1*`.
- **dynamic** - If you choose this option, the columns are created without a specified width. Entering content into a cell changes the rendered width dynamically. If you change the width by dragging a column in **Author** mode, a dialog box will be displayed that asks you if you want to switch to proportional or fixed column widths.

Frame

Allows you to specify a value for the `@frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `@conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `@conref` target. For more information, see https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html.

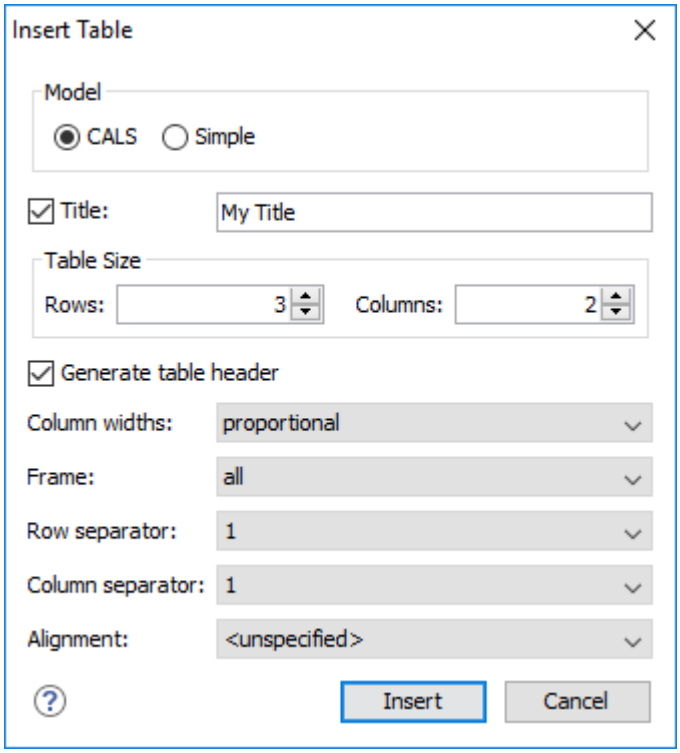
Note:
The options in the **Insert Table** dialog box for DITA documents are persistent, so changes made in one session will carry over to another.

When you click **Insert**, a simple table is inserted into your document at the current cursor position.

Inserting a CALS Table Model (OASIS Exchange Table)

To insert an OASIS Exchange Table (**CALS**), select the **Insert Table** action on the toolbar or from the contextual menu (or the **Table** submenu from the **DITA** menu). The **Insert Table** dialog box appears. Select **CALS** for the table **Model**. This model allows you to configure more properties than the *Simple* model.

Figure 789. Insert Table Dialog Box - CALS Model



The dialog box allows you to configure the following options when you select the **CALS** table model:

Title

If this checkbox is selected, you can specify a title for your table in the adjacent text box.

Table Size

Allows you to choose the number of **Rows** and **Columns** for the table.

Generate table header

If selected, an extra row will be inserted at the top of the table to be used as the table header.

Column widths

Allows you to specify the type of properties for column widths (`@colwidth` attribute). You can choose one of the following properties for the column width:

- **proportional** - The width is specified in proportional (relative) units of measure. The proportion of the column is specified in a `@colwidth` attribute with the values listed as the number of shares followed by an asterisk. The value of the shares is totaled and rendered as a percent. For example, `colwidth="1* 2* 3*"` causes widths of 16.7%, 33.3%,

and 66.7%. When entering content into a cell in one column, the width proportions of the other columns are maintained. If you change the width by dragging a column in **Author** mode, the values of the `@colwidth` attribute are automatically changed accordingly. By default, when you insert, drag and drop, or copy/paste a column, the value of the `@colwidth` attribute is `1*`.

- **dynamic** - If you choose this option, the columns are created without a specified width (`@colwidth` attribute). Entering content into a cell changes the rendered width dynamically. If you change the width by dragging a column in **Author** mode, a dialog box will be displayed that asks you if you want to switch to proportional or fixed column widths.
- **fixed** - The width is specified in fixed units. By default, the `pt` unit is inserted, but you can change the units in the **colspecs** (column specifications) section above the table or in **Text** mode. The following units are allowed: `pt` (points), `cm` (centimeters), `mm` (millimeters), `pi` (picas), `in` (inches).

Frame

Allows you to specify a value for the `@frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `@conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `@conref` target. For more information, see https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html.

Row separator

Specifies whether or not to include row separators (`@rowsep` attribute). The allowed values are: `0` (no separator) and `1` (include separators).

Column separator

Specifies whether or not to include column separators (`@colsep` attribute). The allowed values are: `0` (no separator) and `1` (include separators).

Alignment

Specifies the alignment of the text within the table (`@align` attribute). The allowed values are:

- **left** - Aligns the text to a left position.
- **right** - Aligns the text to a right position.
- **center** - Aligns the text to a centered position.

- **justify** - Stretches the line of text so that it has equal width.

> **Note:**
> The `justify` value cannot be rendered in **Author** mode, so you will only see it in the output.

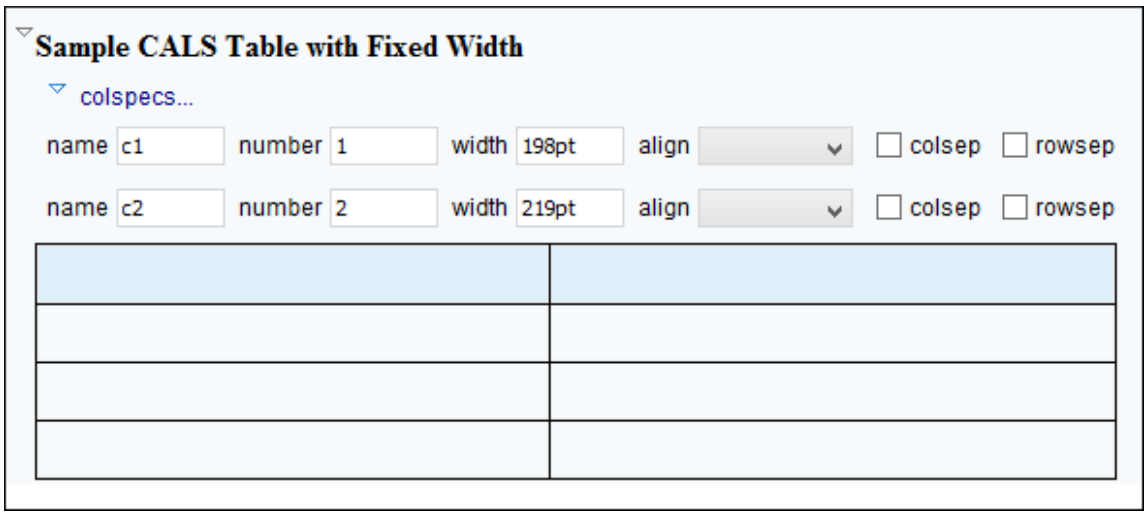
- **char** - Aligns text to the leftmost occurrence of the value specified on the `@char` attribute for alignment.
- **-dita-use-conref-target** - Normally, when using a `@conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `@conref` target. For more information, see https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html.

> **Note:**
> The options in the **Insert Table** dialog box for DITA documents are persistent, so changes made in one session will carry over to another.

When you click **Insert**, a CALS table is inserted into your document at the current cursor position.

When you insert a CALS table, you see a link for setting the *colspecs* (column specifications) of your table. Click the link to open the controls that allow you to adjust various column properties. Although they appear as part of the **Author** mode *(on page 363)*, the *colspecs* link and its controls will not appear in your output. They are just there to make it easier to adjust how the columns of your table are formatted.

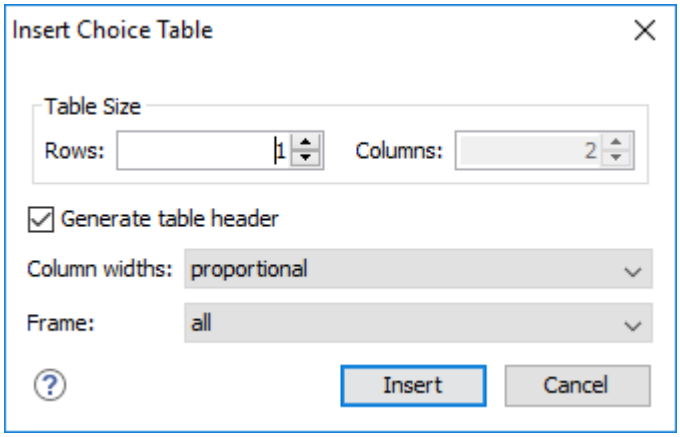
Figure 790. CALS Table in DITA



Inserting a Choice Table Model

To insert a **Choice** table within a `<step>` element in a DITA Task document, select the **Insert Table** action on the toolbar or in the **Insert** submenu from the contextual menu (or the **Table** submenu from the **DITA** menu), or select **choicetable** from the *Content Completion Assistant (on page 3418)*. The **Insert Table** dialog box appears. Select **Simple** for the table **Model**.

Figure 791. Insert Table Dialog Box - Choice Model



The dialog box allows you to configure the following options when you insert a *Choice* table model within a DITA Task:

Table Size

Allows you to choose the number of **Rows** and **Columns** for the table.

Generate table header

If selected, an extra row will be inserted at the top of the table to be used as the table header.

Column widths

Allows you to specify the type of properties for column widths (`@colwidth` attribute). You can choose one of the following properties for the column width:

- **proportional** - The width is specified in proportional (relative) units of measure. The proportion of the column is specified in a `@relcolwidth` attribute with the values listed as the number of shares followed by an asterisk. The value of the shares is totaled and rendered as a percent. For example, `relcolwidth="1* 2* 3*"` causes widths of 16.7%, 33.3%, and 66.7%. When entering content into a cell in one column, the width proportions of the other columns are maintained. If you change the width by dragging a column in **Author** mode, the values of the `@relcolwidth` attribute are automatically changed accordingly. By default, when you insert, drag and drop, or copy/paste a column, the value of the `@relcolwidth` attribute is `1*`.
- **dynamic** - If you choose this option, the columns are created without a specified width. Entering content into a cell changes the rendered width dynamically. If you change the width by dragging a column in **Author** mode, a dialog box will be displayed that asks you if you want to switch to proportional or fixed column widths.

Frame

Allows you to specify a value for the `@frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.

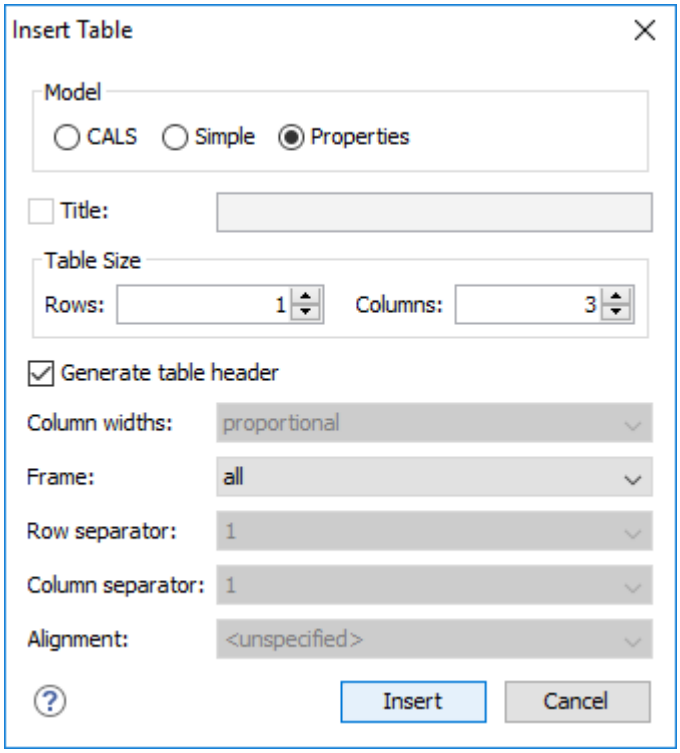
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `@conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `@conref` target. For more information, see https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html.

When you click **Insert**, a *Choice* table is inserted into your DITA Task document at the current cursor position (within a `<step>` element).

Inserting a Properties Table Model

To insert a **Properties** table within a `<refbody>` element in a DITA Reference document, select the **Insert Table** action on the toolbar or in the **Insert** submenu from the contextual menu (or the **Table** submenu from the **DITA** menu), or select **properties(wizard)** from the *Content Completion Assistant (on page 3418)*. The **Insert Table** dialog box appears. Select **Properties** for the table **Model**.

Figure 792. Insert Table Dialog Box - Properties Model



The dialog box allows you to configure the following options when you insert a *Properties* table model within a DITA Reference:

Table Size

Allows you to choose the number of **Rows** and **Columns** for the table.

Generate table header

If selected, an extra row will be inserted at the top of the table to be used as the table header.

Frame

Allows you to specify a value for the `@frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `@conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `@conref` target. For more information, see https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html.

When you click **Insert**, a *Properties* table is inserted into your DITA Reference document at the current cursor position (within a `<refbody>` element).

Editing an Existing Table

You can edit the structure of an existing table using the table buttons on the toolbar (or in the contextual menu) to add or remove cells, rows, or columns, and to set basic table properties. Additional attributes can be used to fine-tune the formatting of your tables by using the **Attributes** view *(on page 638)* (**Window > Show View > Attributes**). See the DITA documentation for a full explanation of these attributes.

You can also use the  **Table Properties (Ctrl + T (Command + T on macOS))** *(on page 3175)* action from the toolbar or contextual menu (or **DITA** menu) to modify many of the properties of the table *(on page 3175)*.

Also, remember that underneath the visual representation, both table models are really just XML. If necessary, you can edit the XML directly by switching to **Text** mode *(on page 362)*.

You can use normal copy/paste shortcuts to move content between cells. Oxygen XML Editor includes a *Smart Paste* feature *(on page 623)* that preserves certain style and structure information when pasting content.

Tip:
When copying a multiple selection of table cells and pasting them outside the table, a new table will be created. When pasting into space-preserved elements, the cell content will be pasted as plain text.

Related Information:
Editing Tables in Author Mode *(on page 695)*

DITA Table Layouts

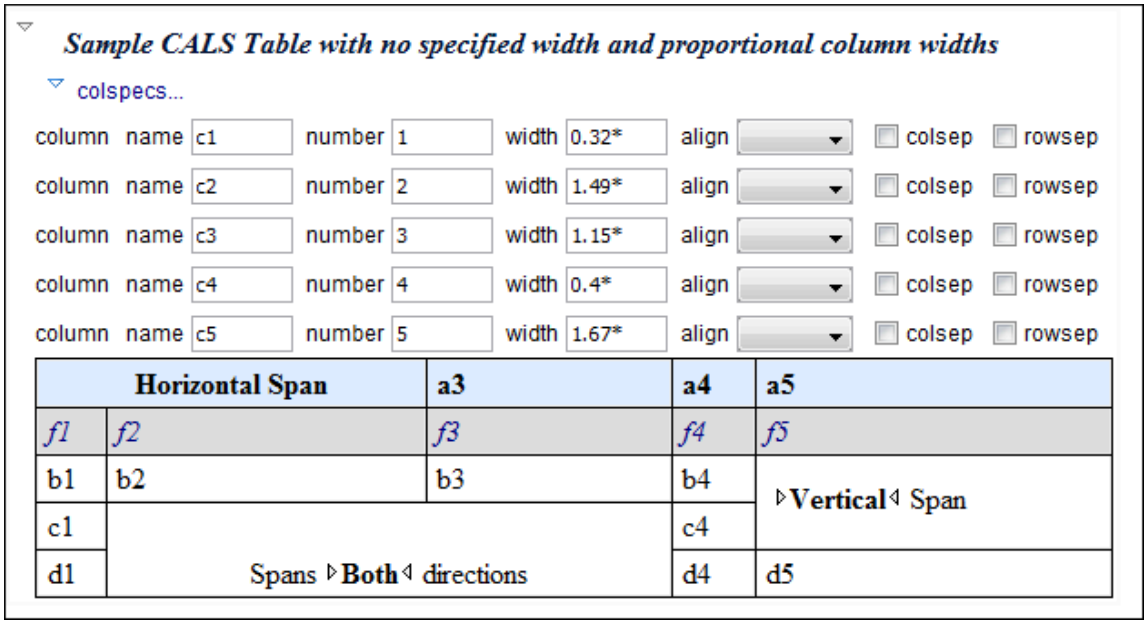
Depending on the context, DITA accepts the following table layouts:

- *CALS* table model *(on page 3173)*
- *Simple* table model *(on page 3173)*
- *Choice* table model *(on page 3174)*
- *Properties* table model *(on page 3174)*

CALS Table Model Layout

The **CALS** table model allows for more flexibility and table customization than other models. When choosing a **CALS** table model from the **Insert Table** dialog box, you have access to more configurable properties. The layout of a **CALS** table includes a **colspecs** section that allows you to easily configure some properties without opening the **Table Properties** dialog box. For example, you can change the value of column widths (`@colwidth` attribute) or the text alignment (`@align` attribute). Although they appear as part of the **Author** mode *(on page 363)*, the *colspecs* link and its controls will not appear in your output. They are just there to make it easier to adjust how the columns of your table are formatted.

Figure 793. CALS Table in DITA



Tip:
A sample plugin is available that can be used as inspiration to add support for CALS tables in any XML document: Sample Plugin: Add CALS Support for any XML Document.

Simple Table Model Layout

When choosing a **Simple** table model from the **Insert Table** dialog box, you only have access to configure a few properties. For example, you can choose the number of rows and columns, specify values for frames, and

choose from a few types of properties for the column width. The layout of this type of table is very simple, as the name suggests.

Figure 794. DITA Simple Table

Header 1	Header 2
Column 1	Column 2

Choice Table Model Layout

A **Choice** table model is used within a `<step>` element in a DITA Task document to describe a series of optional choices that a user must make before proceeding. The `<choicetable>` element is a useful device for documenting options within a single step of a task. You can insert *Choice* tables in DITA Task documents either by selecting **choicetable** from the *Content Completion Assistant (on page 3418)* (within a `<step>` element) or by using the **Insert Table** action on the toolbar or from the contextual menu). The options and layout of a *Choice* table is similar to the *Simple* table model.

Figure 795. DITA Choice Table

Option	Description
Opt A	
Opt B	
Opt C	

Properties Table Model Layout

A **Properties** table model is used within a `<refbody>` element in a DITA Reference document to describe a property (for example, its type, value, and description). You can insert *Properties* tables in DITA Reference documents either by selecting **properties(wizard)** from the *Content Completion Assistant (on page 3418)* (within a `<refbody>` element) or by using the **Insert Table** action on the toolbar (or from the contextual menu) and selecting **Properties** for the **Model**. The layout of a *Properties* table is very simple. It allows for a maximum of 3 columns (typically for property type, value, and description) and the only options available are for whether or not you want a header row and for specifying frames (borders).

Figure 796. DITA Properties Table

Property Type	Property Value	Property Description
A	B	C

Table Validation in DITA

Oxygen XML Editor reports table layout problems that are detected in manual or automatic validations. When you validate a *DITA map (on page 3419)* with the **Validate and Check for Completeness** action, if the **Report table layout problems** option *(on page 3123)* is selected in the **DITA Map Completeness Check** dialog

box, table layout problems will be reported in the validation results. The types of errors that may be reported for DITA table layout problems include:

CALS Tables

- A row has fewer cells than the number of columns detected from the table `@cols` attribute.
- A row has more cells than the number of columns detected from the table `@cols` attribute.
- A cell has a vertical span greater than the available rows count.
- The number of `<colspecs>` is different than the number of columns detected from the table `@cols` attribute.
- The number of columns detected from the table `@cols` attribute is different than the number of columns detected in the table structure.
- The value of the `@cols`, `@rowsep`, or `@colsep` attributes are not numeric.
- The `@namest`, `@nameend`, or `@colname` attributes point to an incorrect column name.

Simple or Choice Tables

A row has fewer cells than the number of table columns.

Editing Table Properties in DITA

To customize the look of a table in DITA, place the cursor anywhere in a table and invoke the **Table Properties (Ctrl + T (Command + T on macOS))** action from the toolbar or the **Table** submenu of the contextual menu (or **DITA** menu). This opens the **Table properties** dialog box.

The **Table properties** dialog box allows you to set specific properties to the table elements. The options that are available depend on the context and location within the table where the action was invoked.

Note:
Some properties allow the following special values, depending on the context and the current properties or values:

- **<not set>** - Use this value if you want to remove a property.
- **<preserve>** - If you select multiple elements that have the same property set to different values, you can choose this value to keep the values that are already set. In some cases it can also be used to keep the current non-standard value for a particular property.

Edit Table Properties for a CALS Table Model

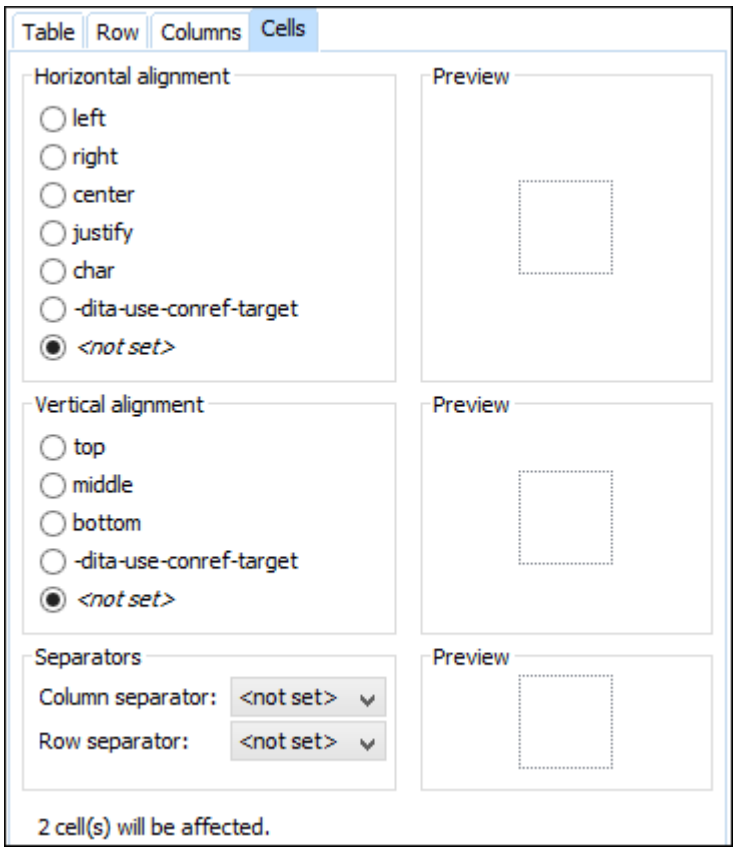
For a **CALS** table model, the **Table properties** dialog box includes four tabs of options:

- **Table** tab - The options in this tab apply to the entire table.
- **Row** tab - The options in this tab apply to the current row or selection of multiple rows. A message at the bottom of the tab tells you how many rows will be affected.

- **Column** tab - The options in this tab apply to the current column or selection of multiple columns. A message at the bottom of the tab tells you how many columns will be affected.
- **Cell** tab - The options in this tab apply to the current cell or selection of multiple cells. A message at the bottom of the tab tells you how many cells will be affected.

The options in four tabs include a **Preview** pane that shows a representation of the modification.

Figure 797. Table Properties Dialog Box with Cell Tab Selected (DITA CALS Table Model)



The options in the four tabs include the following:

Horizontal alignment (Available in the Table, Column, and Cell tabs)

Specifies the horizontal alignment of text within the current table/column/cell or selection of multiple columns/cells (`@align` attribute). The allowed values are as follows:

- **left** - Aligns the text to a left position.
- **right** - Aligns the text to a right position.
- **center** - Aligns the text to a centered position.
- **justify** - Stretches the line of text so that it has equal width.

> **Note:**
> The `justify` value cannot be rendered in **Author** mode, so you will only see it in the output.

- **char** - Aligns text to the leftmost occurrence of the value specified on the `@char` attribute for alignment.
- **-dita-use-conref-target** - Normally, when using a `@conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `@conref` target. For more information, see https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html.

Vertical alignment (Available in the Row and Cell tabs)

Specifies the vertical alignment of text within the current row/cell or selection of multiple rows/cells (`@valign` attribute). The allowed values are as follows:

- **top** - Aligns the text at the top of the cell.
- **middle** - Aligns the text in a vertically centered position.
- **bottom** - Aligns the text at the bottom of the cell.
- **-dita-use-conref-target** - Normally, when using a `@conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `@conref` target. For more information, see https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html.

Column separator (Available in the Table, Column, and Cell tabs)

Specifies whether or not to include column separators (borders/grid lines) in the form of the `@colsep` attribute. The allowed values are: `0` (no separator) and `1` (include separators).

Row separator (Available in all four tabs)

Specifies whether or not to include row separators (borders/grid lines) in the form of the `@rowsep` attribute. The allowed values are: `0` (no separator) and `1` (include separators).

Frame (Available only in the Table tab)

Allows you to specify a value for the `@frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `@conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `@conref` target. For more information, see https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html.

Edit Table Properties for a Simple, Choice, or Properties Table Model

For a *Simple*, *Choice*, *Properties* table model, the **Table properties** dialog box only allows you to edit a few options.

Table tab

Frame

Allows you to specify a value for the `@frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `@conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `@conref` target. For more information, see https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html.

Row tab (not available for *Properties* tables)

Row type

Allows you change the row to a body or header type of row.

Adding Tables in DITA Topics *(on page 3165)*
Editing Tables in Author Mode *(on page 695)*

Adding MathML Equations in DITA Topics

You can add MathML equations in a DITA document open in the **Author** visual editing mode using one of the following methods:

- Embed MathML directly into a DITA topic. You can use **Insert >** Σ **Insert Equation** from the contextual menu or the main menu **DITA > Insert > Insert Equation** action to insert a MathML equation. Clicking on the equation will open a **MathML Editor** where you can edit the code.
- Reference an external MathML file as an image, using the **Insert Image** action that is available on the DITA toolbar (or from the **DITA > Insert** menu).

Publishing Notes:

- MathML equations contained in DITA topics can be published out-of-the-box in PDF using the **DITA PDF** transformation scenario.
- The **DITA Map PDF - based on HTML5 & CSS** transformation scenario *(on page 1839)* support MathML equations *(on page 2016)*.
- For details about HTML output, see How to View MathML Equations in HTML Output *(on page 1773)*.
- For other publishing formats, you might need to employ additional customizations for handling MathML content.

Adding LaTeX Equations in DITA Topics

LaTeX is a high-quality typesetting system that includes features designed for the production of technical and scientific documentation. LaTeX can also be used to express mathematical formulas in a textual format. By default, web browsers and PDF readers do not have support to show mathematical equations written in LaTeX, but there are open-source projects that can read LaTeX and convert it to other image types.

Adding support for writing LaTeX equations in a DITA topic implies three stages:

1. Find a way to write the equation in the DITA XML content. You can either create a DITA DTD specialization and add a new element (for example, called `<latex>` and it extends the DITA `<foreign>` element). Alternatively, you can directly use the DITA `<foreign>` element with a specific `@outputclass` attribute value:

```
<!DOCTYPE topic PUBLIC "-//OASIS//DTD DITA Topic//EN" "topic.dtd">
<topic id="testEquation">
  <title>Test equation</title>
  <body>
    <p><foreign outputclass="embed-latex">L' = {L}{\sqrt{1-\frac{v^2}{c^2}}}</foreign></p>
  </body>
</topic>
```

2. If you want Oxygen XML Editor to properly present the LaTeX equation when editing in the **Author** visual mode, you need a plugin that converts the equation content to an image. There is a sample plugin that does that here: https://github.com/oxygenxml/wsaccess-javascript-sample-plugins/tree/master/latex-images-support. You can download and copy the plugin folder **latex-images-support** to the Oxygen XML Editor **plugins** folder, then restart Oxygen XML Editor.
3. The final stage would be to publish the content to HTML-based or PDF output. The following DITA Open Toolkit plugin automatically converts LaTeX images to SVG when publishing: https://github.com/oxygenxml/dita-latex.

DITA Questions and Answers Topic Type

You can create a new DITA *Questions and Answers* topic using the Oxygen XML Editor **File > New** file wizard. It is found in the **Framework templates > DITA > Topics > RNG** folder (or you can search for it using the search filter at the top of the dialog box).

This type of topic groups together multiple question/answer sections and can be used to create a frequently asked questions document (for example).

There is an **Insert Question/Answer Group** action that is available on the toolbar and in the **DITA Q/A** main menu that can be used to insert multiple question/answer groups. You can also define multiple questions in the same group, all paired to the same answer.

When producing WebHelp output from DITA content, Q/A-specific **Google Structured Data** in the HTML files is generated from these Questions and Answers DITA topic types.

Related information

How to Generate Google Structured Data *(on page 1779)*

DITA Topic Author Mode Actions

A variety of actions are available for DITA documents that can be found in **DITA** menu, toolbar, contextual menu, and the *Content Completion Assistant (on page 3418)*.

DITA Toolbar Actions

The following default actions are available on the DITA toolbar when editing in **Author** mode (by default, most of them are also available in the **DITA** menu and in various submenus of the contextual menu):

Bold

Surrounds the selected text with a `<b>` tag. You can use this action on multiple non-contiguous selections.

Italic

Surrounds the selected text with an `<i>` tag. You can use this action on multiple non-contiguous selections.

Underline

Surrounds the selected text with a `<u>` tag. You can use this action on multiple non-contiguous selections.

Link Actions Drop-Down Menu

The following link actions are available from this menu:

Cross Reference

Opens the **Cross Reference (xref)** dialog box *(on page 3255)* that allows you to insert a link to a target DITA resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map (on page 3419)* structure. Once the target resource has been selected, you can also target specific elements within that resource. For more information, see Linking in DITA Topics *(on page 3254)*.

File Reference

Opens the **File Reference** dialog box *(on page 3255)* that allows you to insert a link to a target non-DITA file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. For more information, see Linking in DITA Topics *(on page 3254)*.

Web Link

Opens the **Web Link** dialog box *(on page 3255)* that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. For more information, see Linking in DITA Topics *(on page 3254)*.

Related Link to Topic

Opens the **Cross Reference (xref)** dialog box *(on page 3256)* that allows you to insert a link to a target DITA resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics *(on page 3254)*.

Tip:
You can use the **Find Similar Topics** action (available in the contextual menu or **DITA** menu) to quickly find related topics that can be added as related links. It opens the **Open/Find Resource** view and performs a search using text content from the `<title>`, `<shortdesc>`, `<keyword>`, and `<indexterm>` elements.

Related Link to File

Opens the **File Reference** dialog box *(on page 3256)* that allows you to insert a link to a target non-DITA file resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics *(on page 3254)*.

Related Link to Web Page

Opens the **Web Link** dialog box *(on page 3256)* that allows you to insert a link to a target web-related resource in a related links section at the bottom of the current document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics *(on page 3254)*.

Insert Image

Opens the **Insert Image** dialog box *(on page 3152)* that allows you to configure the properties of an image to be inserted into a DITA document at the cursor position.

Insert Media Resource

Opens the **Insert Media** dialog box *(on page 3155)* that allows you to select and configure the properties of a media object to be inserted into a DITA document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted in an `<object>` element and it is rendered in **Author** mode so that it can be played directly from there.

Insert Section Drop-Down Menu

The following insert actions are available from this menu:

Insert Section

Inserts a new `<section>` element in the document, depending on the current context.

Insert Concept

Inserts a new `<concept>` element, depending on the current context. Concepts provide background information that users must know before they can successfully work with a product or interface.

Insert Task

Inserts a new `<task>` element, depending on the current context. Tasks are the main building blocks for task-oriented user assistance. They generally provide step-by-step instructions that will help a user to perform a task.

Insert Topic

Inserts a new `<topic>` element, depending on the current context. Topics are the basic units of DITA content and are usually organized around a single subject.

Insert Reference

Inserts a new `<reference>` element, depending on the current context. A reference is a top-level container for a reference topic.

Insert Note

Inserts a new `<note>` element, depending on the current context.

Insert Codeblock

Inserts a new `<codeblock>` element, depending on the current context.

Insert Intent Question

Inserts a new special `<data>` element that contains a question or intent. The intent can be used to generate Google Structured data *(on page 1779)* content in WebHelp Responsive output.

Insert Paragraph

Inserts a new paragraph at current cursor position.

Reuse Content

This action provides a mechanism for reusing content fragments. It opens the **Reuse Content** dialog box *(on page 3224)* that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include content references (`@conref`) *(on page 3225)*, content key references (`@conkeyref`) *(on page 3227)*, or key references to metadata (`@keyref`) *(on page 3230)*.

Insert step or list item

Inserts a new list or step item in the current list type.

Insert Unordered List

Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a *block element (on page 3417)*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

> **Note:**
> If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

Insert Row

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Delete Row(s)

Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Column

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Delete Column(s)

Deletes the table column located at the cursor position or multiple columns in a selection.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

DITA Contextual Menu Actions

The following actions are available in the contextual menu when editing in **Author** mode (most of them are also available in the **DITA** menu at the top of the interface):

Add File to Review Task

This action can be used to add the current document to a task in the **Content Fusion Tasks Manager** view. **Oxygen Content Fusion** is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on *(on page 2651)*. To fully take advantage of all of the benefits and features of **Content Fusion**, your organization will need an **Oxygen Content Fusion Enterprise Server**. For more information, see the **Oxygen Content Fusion** website.

Edit Attributes

Displays an in-place attributes editor *(on page 640)* that allows you to manage the attributes of an element.

Edit Profiling Attributes

Allows you to change the profiling attributes *(on page 680)* defined on all selected elements.

Cut (Ctrl + X (Command + X on macOS))

Removes the currently selected content from the document and places it in the clipboard.

Copy (Ctrl + C (Command + C on macOS))

Places a copy of the currently selected content in the clipboard.

Paste (Ctrl + V (Command + V on macOS))

Inserts the current clipboard content into the document at the cursor position.

Paste special submenu

This submenu includes the following special paste actions that are specific to the DITA *framework*:

Paste as content reference

Inserts a content reference (a DITA element with a `@conref` attribute) to the DITA XML element from the clipboard. An entire DITA XML element with an ID attribute must be present in the clipboard when the action is invoked. The `conref` attribute will point to this ID value.

Paste as content key reference

Allows you to indirectly reference content using the `@conkeyref` attribute. When the DITA content is processed, the key references are resolved using key definitions from *DITA maps (on page 3419)*. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the **Context** combo box points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Paste as link

Looks for the first element with an ID value in the clipboard and inserts an `<xref>` that points to that element. If no elements with an ID value are found, a message

will appear that informs you that to use this action, the clipboard contents must include at least one element with a declared ID.

Paste as link (keyref)

Inserts a link to the element that you want to reference. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the **Context** combo box points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Insert submenu

This submenu includes the following insert actions that are specific to the DITA *framework*:

 **Insert Table**

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a *block element (on page 3417)*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note:
If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

 **Insert Image**

Inserts an image reference *(on page 730)* at the cursor position. Depending on the current location, an image-type element is inserted.

 **Insert Media Resource**

Opens a **Choose Media** dialog box *(on page 758)* that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in **Author** mode so that it can be played directly from there.

Insert Equation

Opens the **XML Fragment Editor** that allows you to insert and edit MathML notations *(on page 760)*.

Insert Note

Inserts a new `<note>` element at the current cursor position.

Insert Code Block

Inserts a new `<codeblock>` element at current cursor position.

Insert Menu Cascade

Inserts a new `<menucascade>` element at current cursor position.

Insert Label

Inserts a special label keyword in the prolog. The label is helpful for searching WebHelp Responsive output for similar topics with the same label.

Insert Paragraph

Inserts a new `<p>` (paragraph) element at current cursor position.

Insert Section

Inserts a new `<section>` element in the document, depending on the current context.

Insert Topic

Inserts a new `<topic>` element, depending on the current context. Topics are the basic units of DITA content and are usually organized around a single subject.

Insert Entity

Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- #<*decimal value*> - e.g. #65
- &#<*decimal value*> - e.g. &#65
- #x<*hexadecimal value*> - e.g. #x41
- &#x<*hexadecimal value*> - e.g. &#x41

Style submenu

This submenu includes the following text styling actions:

Bold

Emphasizes the selected text by surrounding it with a `<b>` (bold) tag. You can use this action on multiple non-contiguous selections.

Italic

Emphasizes the selected text by surrounding it with an `<i>` (italic) tag. You can use this action on multiple non-contiguous selections.

Underline

Emphasizes the selected text by surrounding it with a `<u>` (*underline*) tag. You can use this action on multiple non-contiguous selections.

Subscript

Surrounds the selected text with a `<sub>` (subscript) tag, used for inserting a character (number, letter, or symbol) that will appear slightly below the baseline and slightly smaller than the rest of the text.

Superscript

Surrounds the selected text with a `<sup>` (superscript) tag, used for inserting a character (number, letter, or symbol) that will appear slightly above the baseline and slightly smaller than the rest of the text.

Code

Surrounds the selected text with a `<codeph>` tag.

UI Control

Surrounds the selected text with a `<uicontrol>` tag, used to mark up names of buttons, entry fields, menu items, or other interface objects.

Filepath

Surrounds the selected text with a `<filepath>` tag, used to indicate the name, and optionally the location of a referenced file. You can specify the directory that contains the file and other directories that may precede it in the system hierarchy.

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the **Image Map Editor** dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Table Actions

A variety of table editing actions are available in the contextual menu when it is invoked on a table (depending on the context, the table-related actions are promoted to the top level of the contextual menu and the **Other Actions** submenu provides access to the other actions):

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Delete Row(s)

Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Delete Column(s)

Deletes the table column located at the cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.

Link submenu

The following link actions are available from this submenu:

Cross Reference

Opens the **Cross Reference (xref)** dialog box *(on page 3255)* that allows you to insert a link to a target DITA resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map (on page 3419)* structure. Once the target resource has been selected, you can also target specific elements within that resource. For more information, see Linking in DITA Topics *(on page 3254)*.

File Reference

Opens the **File Reference** dialog box *(on page 3255)* that allows you to insert a link to a target non-DITA file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. For more information, see Linking in DITA Topics *(on page 3254)*.

Web Link

Opens the **Web Link** dialog box *(on page 3255)* that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. For more information, see Linking in DITA Topics *(on page 3254)*.

Related Link to Topic

Opens the **Cross Reference (xref)** dialog box *(on page 3256)* that allows you to insert a link to a target DITA resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics *(on page 3254)*.

> **Tip:**
> You can use the **Find Similar Topics** action (available in the contextual menu or **DITA** menu) to quickly find related topics that can be added as related links. It opens the **Open/Find Resource** view and performs a search using text content from the `<title>`, `<shortdesc>`, `<keyword>`, and `<indexterm>` elements.

Related Link to File

Opens the **File Reference** dialog box *(on page 3256)* that allows you to insert a link to a target non-DITA file resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics *(on page 3254)*.

Related Link to Web Page

Opens the **Web Link** dialog box *(on page 3256)* that allows you to insert a link to a target web-related resource in a related links section at the bottom of the current document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics *(on page 3254)*.

Sort

Available when invoked on a list, it opens a dialog box where you can configure a sorting operation for an entire list or a selection of list items.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements listed in the **ID Options** dialog box that are found in the current selection.

Note:
The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `@id` attribute.

Reuse submenu

This submenu includes the following actions regarding reusing content in DITA:

Reuse Content

This action provides a mechanism for reusing content fragments. It opens the **Reuse Content** dialog box *(on page 3224)* that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include content references (`@conref`) *(on page 3225)*, content key references (`@conkeyref`) *(on page 3227)*, or key references to metadata (`@keyref`) *(on page 3230)*.

Push Current Element

Opens the **Push current element** dialog box *(on page 3233)* that allows content from a source topic to be inserted into another topic without any special coding in the topic where the content will be re-used.

Edit Content Reference

This action is available for elements with a `@conref` or `@conkeyref` attribute. It opens the **Edit Content Reference** dialog box that allows you to edit the source location (or key) and source element of a content reference (or content key reference), and the reference details (`@conref`/`@conkeyref` and `@conrefend` attributes). For more information, see Reuse Content Dialog Box *(on page 3224)*.

Replace Reference with Content

Replaces the referenced fragment (`@conref` or `@conkeyref`) at the cursor position with its content from it source. This action is useful if you want to make changes to the content in the currently edited document without changing the referenced fragment in its source location. If the source content includes references to other topics/resources (*hrefs*), the operation also resolves those references relative to the new location. Attributes are preserved according to the following priority:

1. Attributes from the elements in the current document that reference other content are preserved except for attributes with a `-dita-use-conref-target` value.
2. Attributes from the referenced content are brought into the replaced elements in the current document except for `@id` attributes.

Replace All References with Content

Replaces all referenced fragments (`@keyref`, `@conref`, or `@conkeyref`) in the current document with the content. Attributes are preserved according to the following priority:

1. Attributes from the elements in the current document that reference other content are preserved except for attributes with a `-dita-use-conref-target` value.
2. Attributes from the referenced content are brought into the replaced elements in the current document except for `@id` attributes.

For *keyrefs* inside `<xref>` or `<link>` elements, the `@keyref` attribute is changed to an `@href` attribute, while the rest of the content for the *keyref* is replaced with its source content.

If the source content includes references to other topics/resources (*hrefs*), the operation also resolves those references relative to the new location.

Remove Content Reference

Removes the content reference (`@conref` or `@conkeyref`) inside the element at the cursor position.

Create Reusable Component

Opens a dialog box that helps you to create a reusable component from the current element or selection of elements. If the **Replace selection with content reference** option is selected in the dialog box, the selection will be replaced with a content reference (`@conref`). If multiple elements are selected (for example, multiple steps or list items), the selection will be replaced with a content reference range (`@conref` and `@conrefend`). For more information, see Creating a Reusable Content Component *(on page 3236)*.

Insert Reusable Component

Inserts a reusable component at cursor location. For more information, see Inserting a Reusable Content Component *(on page 3237)*.

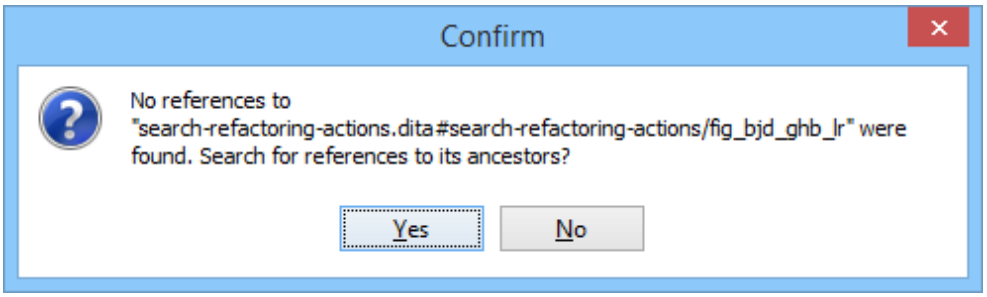
Extract Topic From Selection

Creates a new DITA topic from a selection of content in the current topic.

 **Search References (Ctrl + Shift + G (Command + Shift + G on macOS))**

Finds the references to the `@id` attribute value for the element at the current cursor position, in all the topics contained in the current *DITA map (on page 3419)* (opened in the **DITA Maps Manager** view *(on page 3073)*). If no references are found for the current element, a dialog box will be displayed that offers you the option of searching for references to its ancestor elements.

Figure 798. Search References to Ancestors Dialog Box



Tip:
If you are invoking the action on an image, see Searching for References to Images *(on page 3155)* for details about what will be reported.

Find Similar Topics

Opens the **Open/Find Resource** view and performs a search using text content from the `<title>`, `<shortdesc>`, `<keyword>`, and `<indexterm>` elements. It is helpful for quickly finding related topics that can be added as related links.

Show Key Definition

Available for elements that have a `@conkeyref` or `@keyref` attribute set (or elements with an ancestor element that has a `@conkeyref` or `@keyref` attribute). It computes the key name and opens the *DITA map (on page 3419)* that contains the definition of the key with the element that defines that key selected.

About Element submenu

This submenu includes the following actions:

Style Guide

Opens the **DITA Style Guide Best Practices for Authors** in your browser and displays a topic that is relevant to the element at the cursor position. When editing DITA documents, this action is available in the contextual menu of the editing area (under the **About Element** sub-menu), in the **DITA** menu, and in some of the documentation tips that are displayed by the *Content Completion Assistant (on page 3418)*.

Browse reference manual

Opens a reference to the documentation of the XML element closest to the cursor position in a web browser.

Go to Definition

Moves the cursor to the definition of the current element.

Select submenu

This submenu allows you to select the following:

Element

Selects the entire element at the current cursor position.

Content

Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

Parent

Selects the entire parent element at the current cursor position.

Text submenu

This submenu contains the following actions:

To Lower Case

Converts the selected content to lower case characters.

To Upper Case

Converts the selected content to upper case characters.

Capitalize Sentences

Converts to upper case the first character of every selected sentence.

Capitalize Words

Converts to upper case the first character of every selected word.

Count Words

Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

Note:
The content marked as deleted with *change tracking (on page 3424)* is ignored when counting words.

Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on macOS))

Converts a sequence of hexadecimal characters to the corresponding Unicode character *(on page 473)*. The action can be invoked if there is a selection

containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the `0x` or `0X` prefix. Examples of valid sequences and the characters they will be converted to:

- `0x0045` will be converted to `E`
- `0X0125` to `ĥ`
- `265` to `ŋ`
- `2190` to `←`

> **Note:**
> For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent *(on page 476)*.

Refactoring submenu

Contains a series of actions designed to alter the XML structure of the document:

Toggle Comment

Encloses the currently selected text in a comment, or removes the comment if it is commented.

Move Up (Alt + UpArrow (Option + UpArrow on macOS))

Moves the current node or selected nodes in front of the previous node.

Move Down (Alt + DownArrow (Option + DownArrow on macOS))

Moves the current node or selected nodes after the subsequent node.

Split Element (Alt + Shift + D (Ctrl + Option + D on macOS))

Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

Join Elements

Joins two adjacent *block elements (on page 3417)* that have the same name. The action is available only when the cursor position is between the two adjacent *block elements*. Also, joining two *block elements* can be done by pressing the **Delete** or **Backspace** keys and the cursor is positioned between the boundaries of these two elements.

Surround with Tags (Ctrl + E (Command + E on macOS))

Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.

- If the **Position cursor between tags** option *(on page 220)* is selected in the **Content Completion** preferences page, the cursor is placed between the start and end tag.
- If the **Position cursor between tags** option *(on page 220)* is not selected in the **Content Completion** preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

Surround with '[tag]' (Ctrl + ForwardSlash (Command + ForwardSlash on macOS))

Surround the selected content with the last tag used.

Rename Element

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the **Rename** dialog box.

Delete Element Tags

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the **Delete** or **Backspace** keys.

Remove All Markup

Removes all the XML markup inside the selected block of content and keeps only the text content.

Remove Text

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

DITA-related Refactoring Actions

A variety of built-in XML refactoring operations that pertain to DITA documents with some of the information preconfigured based upon the current context.

Change Topic ID to File Name

Use this operation to change the ID of a topic to be the same as its file name.

Convert CALS Tables to Simple Tables

Use this operation to convert DITA CALS tables to simple tables. If you invoke this operation from a nested table (a table inside a table), only the nested table will be affected. If it is invoked on a parent table that contains nested tables, all of the contained tables will be converted.

Convert conrefs to conkeyrefs

Use this operation to convert `@conref` attributes to `@conkeyref` attributes.

Convert Simple Tables to CALS Tables

Use this operation to convert DITA simple tables to CALS tables. If you invoke this operation from a nested table (a table inside a table), only the nested table will be affected. If it is invoked on a parent table that contains nested tables, all of the contained tables will be converted.

Convert to Concept

Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept).

Convert to General Task

Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). A DITA *General Task* is a less restrictive alternative to the *Strict Task* information type.

Convert to Reference

Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference).

Convert to Task

Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task).

Convert to Topic

Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic).

Convert to Troubleshooting

Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting).

Rename Key

Available when invoked on a key, and can be used to quickly rename a key. It also updates all references to it. Note that it does not work on DITA 1.3 key scopes.

Generate IDs

Use this operation to automatically generate unique IDs for elements.

Attributes Refactoring Actions

Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

Add/Change attribute

Allows you to change the value of an attribute or insert a new one.

Convert attribute to element

Allows you to change an attribute into an element.

Delete attribute

Allows you to remove one or more attributes.

Rename attribute

Allows you to rename an attribute.

Replace in attribute value

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

Comments Refactoring Actions

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

Delete comments

Allows you to delete comments found inside one or more elements.

Elements Refactoring Actions

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

Delete element

Allows you to delete elements.

Delete element content

Allows you to delete the content of elements.

Insert element

Allows you to insert new elements.

Rename element

Allows you to rename elements.

Unwrap element

Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

Wrap element

Allows you to surround elements with element tags.

Wrap element content

Allows you to surround the content of elements with element tags.

Fragments Refactoring Actions

Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

Insert XML fragment

Allows you to insert an XML fragment.

Replace element content with XML fragment

Allows you to replace the content of elements with an XML fragment.

Replace element with XML fragment

Allows you to replace elements with an XML fragment.

Review submenu

This submenu includes the following actions:

 **Track Changes**

Enables or disables the *Track Changes (on page 3424)* support for the current document.

 **Accept Change(s) and Move to Next**

Accepts the *Tracked Change (on page 3424)* located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a *deletion* or *insertion* change, only the selected content is accepted.

 **Accept All Changes**

Accepts all *Tracked Changes (on page 3424)* in the current document.

 **Reject Change(s) and Move to Next**

Rejects the *Tracked Change (on page 3424)* located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a *deletion* or *insertion* change, only the selected content is rejected.

 **Reject All Changes**

Rejects all *Tracked Changes (on page 3424)* in the current document.

 **Comment Change**

Opens a dialog box that allows you to add a comment to an existing *Tracked Change (on page 3424)*. The comment will appear in a callout and a tooltip when

hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

Highlight

Enables the highlighting tool that allows you to mark text in your document.

Colors

Allows you to select the color for highlighting text.

Stop highlighting

Use this action to deactivate the highlighting tool.

Remove highlight(s)

Use this action to remove highlighting from the document.

Add Comment

Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).

Show/Edit Comment

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

Remove Comment

Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.

Manage Reviews

Opens the **Review** view *(on page 675)*.

Manage IDs submenu

This submenu is available for topics that have an associated DTD or schema. It includes the following actions:

Rename in

Renames the ID and all its occurrences. Selecting this action opens the **Rename XML ID** dialog box. This dialog box lets you insert the new ID value and choose the scope of the rename operation.

Search References

Searches for the references of the ID. By default, the scope of this action is the current project. If you configure a scope using the **Select the scope for the Search and Refactor operations** *(on page 843)* dialog box, this scope will be used instead.

Search References in

Searches for the references of the ID. Selecting this action opens the **Select the scope for the Search and Refactor operations** *(on page 843)*.

Search Occurrences in file

Searches for the occurrences of the ID in the current document.

Folding submenu

This submenu includes the following actions:

Toggle Fold

Toggles the state of the current fold.

Collapse Other Folds

Folds all the elements except the current element.

Collapse Child Folds

Folds the elements indented with one level inside the current element.

Expand Child Folds

Unfolds all child elements of the currently selected element.

Expand All

Unfolds all elements in the current document.

Inspect Styles

Opens the **CSS Inspector** view *(on page 651)* that allows you to examine the CSS rules that match the currently selected element.

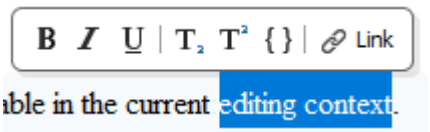
Options

Opens the Author mode preferences page *(on page 183)* where you can configure various options with regard to the **Author** editing mode.

Floating Contextual Toolbar for DITA

Oxygen XML Editor includes a dynamic feature where certain editing contexts will trigger a floating toolbar with common actions that are available in the current editing context.

Figure 799. DITA Floating Contextual Toolbar



The *floating contextual toolbar* is automatically displayed when editing DITA documents in various situations, including:

- When a `<p>`, `<li>`, or `<shortdesc>` element has a selection inside, the floating toolbar includes actions such as **Bold**, **Italic**, **Underline**, a **Link** submenu, and more.
- When an `<image>` or `<xref>` element is selected:
  - If the element has an `@href` attribute, the floating toolbar includes a URL chooser where you can select the appropriate target.
  - If the element has a `@keyref` attribute, the floating toolbar includes a drop-down control where you can select the appropriate target key reference.
- When an `<object>` element is selected:
  - If the element has a `@data` attribute, the floating toolbar includes a URL chooser where you can select the appropriate target.
  - If the element has a `@datakeyref` attribute, the floating toolbar includes a drop-down control where you can select the appropriate target key reference.
- When an element with a `@conref` attribute is selected, the floating toolbar includes actions for editing, removing, or replacing content references.
- When a `<codeblock>` element is selected, the floating toolbar includes a drop-down control where you can select the value of the `@outputclass` attribute.
- When a `<ul>` element is selected, the floating toolbar includes actions for converting it to an ordered list or sorting the list.
- When an `<ol>` element is selected, the floating toolbar includes actions for converting it to an unordered list or sorting the list.
- When an `<li>` or `<step>` element is selected, the floating toolbar includes actions for moving the item up or down in the list/procedure.
- When a `<row>` or `<strow>` element is selected in a table, the floating toolbar includes various table-related actions (such as actions for editing table properties, inserting rows, or deleting rows).
- When an `<entry>` or `<stentry>` element is selected in a table, the floating toolbar includes various table-related actions (such as actions for editing table properties, inserting/deleting rows, or inserting/deleting columns).
- When a `<table>` or `<simpletable>` element is selected, the floating toolbar includes actions for editing table properties or sorting the table.

DITA Drag/Drop (or Copy/Paste) Actions

Dragging a file from the **Project** view *(on page 413)* or **DITA Maps Manager** view *(on page 3073)* and dropping it into a DITA document that is edited in **Author** mode, creates a link to the dragged file (the `<xref>` DITA element with the `@href` attribute) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the **Project** view *(on page 413)* and drop them into a DITA document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the DITA `<image>` element with an `@href` attribute).

Tip:
For information about customizing **Author** mode actions for a particular *framework (on page 3420)* (document type), see the Customizing the Author Mode Editing Experience for a Framework *(on page 2262)* section.

Customizing the Author Mode Editing Experience for a Framework *(on page 2262)*

Working with Markdown Documents in DITA

The Oxygen XML Editor has special features that make it easy to incorporate Markdown documents into a DITA project. This is particularly useful for teams with members who are familiar with Markdown syntax but want to generate their output from DITA projects. The integration between the Markdown editor and DITA includes options to export or convert Markdown documents into DITA topics, as well as a live preview of the edited Markdown content.

Preview

The changes made to the Markdown content can be previewed live in three separate tabs: **DITA**, **XDITA**, and **HTML**.

The **DITA** tab in the *Preview* pane shows how an equivalent DITA topic will look after conversion. Similarly, the **XDITA** tab shows how a Lightweight DITA topic will look after conversion. The **HTML** tab shows a previous of the HTML equivalent.

Keys that are defined in the root map are also resolved in the *Preview* pane in the **XDITA** and **DITA** tabs. If the Markdown document contains profiling attributes (e.g. `## Header 2 {audience=expert}`), the *Preview* pane presents the profiling attributes, colors, and filtered elements similar to **Author** mode (if profiling is set to be shown in the **Profiling/Conditional Text** drop-down *(on page 3078)* in the DITA Maps Manager).

Note:

To make the content generated for preview in the **DITA** and **XDITA** preview tabs more readable and to improve the conversion of Markdown to DITA in the editor, you can add an XML catalog to the XML catalogs *(on page 838)* list. This XML catalog will help with post-processing before the content is displayed. Here is an example of an XML catalog that you can use:

```
<catalog
  xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
  <uri
  name="http://www.oxygenxml.com/ns/preview/postprocess/dita" uri="postProcessDITA.xsl"/>
  <uri
```

```
  name="http://www.oxygenxml.com/ns/preview/postprocess/lwdita" uri="postProcessLWDITA.xsl
"/>
</catalog>
```

Export Markdown as a DITA Topic

The Markdown editor includes an option to quickly convert the current Markdown document into a DITA topic. The **Export as DITA Topic** action is available in the contextual menu.

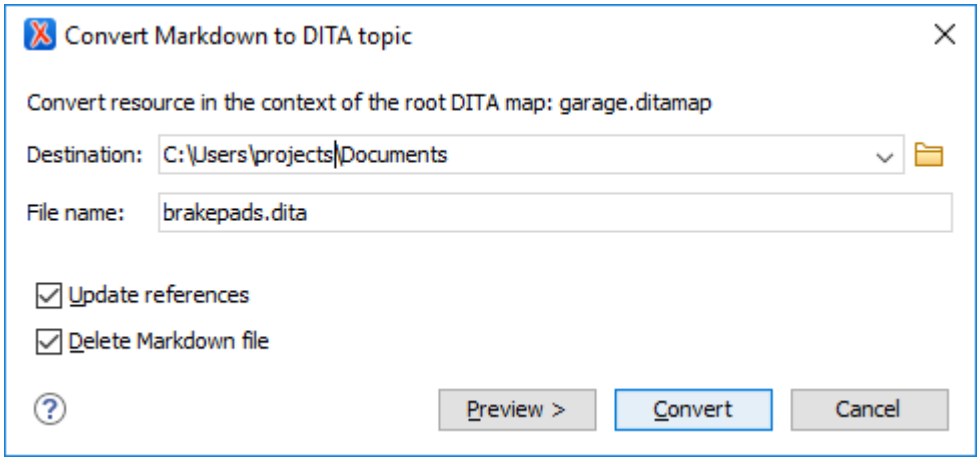
The conversion creates a new XML file that is defined as a DITA topic and opens it in the **Text** editing mode. You can then work with the document as you would with any other DITA topic, although you may need to manually correct some issues where the parser could not properly map Markdown syntax to DITA markup.

Working with Markdown Documents in the DITA Maps Manager

Oxygen XML Editor has some specialized features that allow you to integrate Markdown documents directly into your DITA project using the **DITA Maps Manager** *(on page 3073)*. The following features are available for Markdown documents in the **DITA Maps Manager** view:

- **Insert Reference to Markdown Document** - You can use the **New**, **Reference**, and **Reference to the currently edited file** actions from the **Append Child**, **Insert Before**, or **Insert After** submenu when invoking the contextual menu in the **DITA Maps Manager** to insert a reference to a Markdown document at the selected location in the map. Markdown documents will be inserted as a topic reference (`topicref` element) with the `format` attribute set to `markdown`.
- **Validate Markdown Documents in DITA Maps** - When you use the  **Validate and Check for Completeness** action from the **DITA Maps Manager** toolbar to check the integrity of the structure of a *DITA map*, Markdown documents that are referenced in the *DITA map* will be converted to DITA topics in the background and validated the same as any other DITA topic.
- **Transforming DITA Maps with Markdown Documents** - When transforming *DITA maps* that have Markdown documents referenced, the transformation will convert the Markdown documents to normal DITA output without you needing to manually convert the Markdown documents to DITA topics.
- **Manually Convert Markdown Documents to DITA Topics** - If you need to use DITA semantics that are not possible in Markdown syntax (such as content references, related links, and other DITA-specific syntax), you can manually convert the Markdown document into a DITA topic. To do so, right-click the Markdown document in the **DITA Maps Manager** and select **Refactoring > Convert Markdown to DITA Topic**. This will open a dialog box that allows you to configure options for converting the document to an XML file that is defined as a DITA topic.

Figure 800. Convert Markdown to DITA Topic Dialog Box



This dialog box includes the following options:

Destination

The destination path for the new DITA topic.

File Name

Presents the current name and allows you to change it.

Update references

Select this option to update all references of the file in the *DITA map* and in the files referenced from the *DITA map*.

Delete Markdown file

If selected, the Markdown version of the file is deleted when the document is converted into a DITA file. If deselected (default value), when the document is converted into a DITA file, the original Markdown file is also preserved in its current location.

Preview

Select this button to display a preview of the changes Oxygen XML Editor is about to make.

Convert

Select this button to perform the conversion. If the Markdown file has `format="markdown"`, it will be converted to a DITA topic. If it has `format="mdita"`, it will be converted to a LightWeight DITA topic.

Tip:
Oxygen XML Editor comes with a sample ditamap project for converting Markdown to DITA. Go to the **Project** view *(on page 413)*, open the `sample.xpr` project, and navigate to the `dita/markdown-dita` folder.

Converting Multiple Markdown Documents to DITA

Oxygen XML Editor offers an add-on that contributes actions in the **Tools** menu and contextual menu to enable batch conversion between various formats, including Markdown to DITA. For more information and instructions for installing the add-on, see Batch Documents Converter Add-on *(on page 2657)*.

DITA-Related Markdown Syntax

For a list of Markdown rules and syntax examples that are specific to DITA, see the Markdown DITA Syntax Reference.

Working with DITA-Compatible Documents

Oxygen XML Editor includes powerful dynamic publishing features *(on page 3310)* that allow you to easily integrate **Word, Excel, OpenAPI, HTML, Markdown** documents into a DITA project and have them automatically converted to DITA at the time of publishing. This is especially helpful for teams that have contributors who work with non-DITA documents but want their output to be generated from DITA projects.

Attention:
These features are available with no restrictions when the publishing process is done using the default publishing engine that is bundled in Oxygen XML Editor or if you have integrated the DITA-OT dynamic converter plugin into a custom DITA-OT distribution.

Working with DITA-Compatible Documents in the DITA Maps Manager

Oxygen XML Editor has some specialized features that allow you to integrate DITA-compatible documents directly into your DITA project using the **DITA Maps Manager** *(on page 3073)*. The following features are available in the **DITA Maps Manager** view:

- **Insert References to DITA-Compatible Documents** - You can use the **New**, **Reference**, and **Reference to the currently edited file** actions from the **Append Child**, **Insert Before**, or **Insert After** submenu when invoking the contextual menu in the **DITA Maps Manager** to insert a reference to a **Word, Excel, OpenAPI, HTML or Markdown** document at the selected location in the map. A topic reference (`<topicref>`) element with the appropriate `@format` attribute value will be inserted.
- **Title of Referenced Resources is Displayed** - The title of each referenced DITA-compatible resource is presented in the **DITA Maps Manager** view.

- **Validate DITA-Compatible Documents in DITA Maps** - When you use the  **Validate and Check for Completeness** action from the **DITA Maps Manager** toolbar to check the integrity of the structure of a *DITA map*, DITA-compatible documents that are referenced in the *DITA map* are converted to DITA topics in the background and validated the same as any other DITA topic.
- **IDs Presented When Inserting References** - When inserting topic references, cross references, or content references to content inside DITA-compatible documents, the application presents a list of DITA-specific IDs from the target document.
- **Transform DITA Maps with DITA-Compatible Documents** - When transforming *DITA maps* that have DITA-compatible documents referenced, the transformation converts the documents to normal DITA output without you needing to manually convert the documents to DITA topics.

Converting Multiple DITA-Compatible Documents to DITA

Oxygen XML Editor offers an add-on that contributes actions in the **Tools** menu and contextual menu to enable batch conversions between various formats. For more information and instructions for installing the add-on, see Batch Documents Converter Add-on *(on page 2657)*.

Working with Keys in DITA

DITA uses keys to insert content that may have different values in particular circumstances. Keys provide a way to reference something indirectly. This can make it easier to manage and to reuse content in a various ways.

You can think of keys as like renting a post office box. Instead of the mail going directly from the sender to your house, it now goes to the post office box. You then go to the post office box and bring the mail back to your house. If you move to a new house, your mail still gets to you because it comes to the same post office box. You do not have to send change of address cards to all the people who send you mail. Your mailbox address is the key that makes sure your mail always reaches you, even if you move.

Similarly, if you use keys in your content to reference other content, you do not have to update the source content to change the value of the key or what it points to. You just change the definition of the key.

Defining Keys in DITA Maps

Keys are defined in maps and can then be reused and referenced throughout the whole structure of the map. It is considered best practice to create a separate submap that contains all of the key definitions and reference that submap in the *main (root) map (on page 3424)*. This makes it easier to manage since they're all in one location.

There are two types of key definitions that can be created in a map:

- Key with a value inside a `<keyword>`. To define this type of key, follow these instructions: Key Definition with a Keyword Value *(on page 3108)*.
- Key with a target (for example, to target a resource such as an image or external link). To define this type of key, follow these instructions: Key Definition with a Target *(on page 3109)*.

Using Keys for Values

You can use keys to represent values that may vary depending on the type of output. For instance, you may have several products that share a common feature. When you want to describe that feature, you need a way to insert the name of the product, even though that name is different depending on which product the feature description is being used for. For more information, see Working with Variable Text in DITA *(on page 3237)*.

Assigning Keys to Topics

You can assign a key to a topic and use that key to reference that topic for various purposes, such as reuse or linking. As always, keys are defined in maps, so the key definition is done using the keys attribute of the `<topicref>` element:

```
<topicref href="quick-heat.dita" keys="feature.quick-heat"/>
```

The easiest way to assign keys to a topic (and insert the `<topicref>` element in its *DITA map (on page 3419)*) is to use the **Keys** tab in the **Edit Properties** dialog box *(on page 3111)*. In the **DITA Maps Manager** *(on page 3073)*, invoke the contextual menu on the topic that will have the key assigned and select **Edit Properties**. Go to the **Keys** tab and enter the name of the key in the **Define keys** field.

Once a key is assigned to a topic, you can use it to reference that topic for various purposes:

- You can create a link *(on page 3254)* to it using `<xref keyref="feature.quick-heat">`. This allows you to change the target of the link by changing the topic that is pointed to by the key (for example, by profiling).
- You can use it in a map to create a reference to a topic *(on page 3094)* by key: `<topicref keyref="feature.quick-heat">`. This allows you to change which topic is inserted in the map by the build, by changing the topic that is pointed to by the key.
- You can use it to insert a content reference *(on page 3219)*. In this case, the content reference uses the key to locate the topic to pull content from. It uses a `@conkeyref` attribute: `<procedure conkeyref="feature.quick-heat/preheat-procedure">`. In this example, `feature.quick-heat` is the key,

and `preheat-procedure` is the ID of a procedure within the topic for that key. Using this mechanism, you could have multiple versions of the preheat procedure in various topics and control which one is inserted by changing the topic that is pointed to by the key.

Assigning Keys to Graphics

You can assign a key to an image (using a map to point to the image file *(on page 3109)*) and then insert the image using the key *(on page 3152)*.

Example of a key definition for a targeted image file:

```
<map id="keydefs">
  <!-- product name -->
  <title>Key Definitions</title>
  <keydef keys="image1" href="../img/image1.png" format="png"/>
</map>
```

Working with a Glossary of Terms in DITA

There are several ways to manage a Glossary of Terms in DITA, but it is considered best practices to create a separate submap for the glossary and embed that glossary map in the *main (root) map (on page 3424)*. The actual glossary terms are small *glossary entry* topics that are referenced in the glossary map. You can add links to the glossary terms *(on page 3210)* in the output and you can even define abbreviated forms *(on page 3211)* for terms that have an acronym or some other type of abbreviation.

How to Create a Glossary of Terms in Oxygen XML Editor

Even though there are several ways to create a glossary and reference the glossary terms, the following is the recommended approach:

1. Create a new submap *(on page 3092)* for your glossary and embed it in your main map.
2. Create a glossary entry topic (`<glossentry>`) for each glossary term. The `<glossentry>` element may contain numerous optional glossentry elements, but every glossentry topic must contain a `<glossterm>` and `<glossdef>` element. The `<glossterm>` is the name of the term while the `<glossdef>` is its definition.

Here is an simple example:

```
<glossentry id="ddl">
    <glossterm>Data Definition Language</glossterm>
    <glossdef>A language used for defining database schemas.</glossdef>
</glossentry>
```

The easiest way to create a glossentry topic in Oxygen XML Editor:

a. Click the **New** file wizard button on the toolbar.
b. Type *glossentry* in the search field at the top of the dialog box.
c. Select the **Glossentry** DITA topic type, configure the name and optionally the title, and click **Create**.

3. Reference each glossary entry topic in your glossary submap using the `<glossref>` element. This element requires a `@keys` attribute. Please make sure the `@print` attribute is set to `yes` to show the glossary also in the PDF output.

```
<glossref keys="gloss_ddl" href="ddl.dita" print="yes"/>
```

The easiest way to reference a glossentry in Oxygen XML Editor:

a. With the glossary entry topic opened in the main editor, open the glossary submap in the **DITA Maps Manager**, right-click the map node and select **Append Child > Reference to the currently edited file** (if you already have existing glossentry topics, you can right-click the glossentry where you want to insert the new one and select **Insert After > Reference to the currently edited file**).

Step Result: This opens the **Insert Reference** dialog box *(on page 3099)*.

b. Go to the **Keys** tab and enter a name in the **Define keys** field.
c. Go to the **Attributes** tab and select **Glossary Reference** from the **Reference type** drop-down list at the top of the dialog box.
d. Click **Insert and Close**.

Tip:
You could also group multiple glossentry topics into a single collection by using the `<glossgroup>` element.

How to Create Links to Glossary Terms

To specify that a link is generated in the output from the glossary term to its definition, use the `<term>` element (or `<abbreviated-form>` element as described in the next section *(on page 3211)*) with a `@keyref` attribute that references the corresponding key specified in the `<glossref>`. Of course, the `<glossref>` points to the `<glossentry>` topic where the glossary term is defined.

```
<term keyref="gloss_ddl"/>
```

In the output, the text specified in the `<glossterm>` element is displayed for the glossary term with a link to its glossentry topic that contains its definition.

The easiest way to add a `<term>` element and reference the glossary term in Oxygen XML Editor:

1. Place the cursor at the location where you want to insert a link to the glossary term.
2. In the **DITA Reusable Componts** view *(on page 3242)*, go to the **Keys** tab and use the search filter field at the top of the view to find the key for the particular glossary term.
3. Right-click the key and select **Insert as Keyref > More > Term**.

Using Abbreviated Forms (Acronyms) with Glossary Terms

The `<abbreviated-form>` element can be used for glossary terms that you want to appear in an abbreviated form (such as an acronym). Abbreviated forms are expanded to their full form the first time that they appear in a document, and then all subsequent instances will display the short form (or acronym). You would need to define the long and short forms in the `<glossentry>` and then reference it with the `<abbreviated-form>` element (instead of the `<term>` element).

The recommended best practices for defining the long and short forms would be to use a structure similar to this:

```
<glossentry id="ddl">
  <glossterm>Data Definition Language</glossterm>
  <glossBody>
    <glossSurfaceForm>Data Definition Language (DDL)</glossSurfaceForm>
    <glossAlt>
      <glossAcronym>DDL</glossAcronym>
    </glossAlt>
  </glossBody>
</glossentry>
```

The long form is declared using the `<glossSurfaceForm>` element while the short form is declared using the `<glossAcronym>` element.

Then you need to reference the glossentry that contains the long and short forms using the `<abbreviated-form>` element:

```
<abbreviated-form keyref="gloss_ddl"/>
```

For more information about the recommended best practices for using abbreviations, including information about using multiple languages, see: http://www.oasis-open.org/committees/download.php/29734/AcronymBestPractice_08112008.doc.

Related information

https://docs.oasis-open.org/dita/v1.2/os/spec/langref/abbreviated-form.html

Reusing DITA Content

Reusing content is one of the key features of DITA and DITA provides several methods for reusing content. Oxygen XML Editor provides support for each of these methods.

Reusing Topics in DITA Maps

A DITA topic does not belong to any one publication. You add a DITA topic to a publication by referencing it in a map. You can reference the same topic in multiple maps *(on page 3215)*.

Reusing Content with References and Keys

DITA allows you to reuse content by referencing it in another topic. DITA provides several mechanisms for including content by reference *(on page 3216)* (*conref*, *conkeyref*, *coderef*). A `conref` (content reference) *(on page 3217)* creates a direct reference to a specific element of another topic. A `conkeyref` (content key reference) *(on page 3219)* creates a reference to a key, which then points to a specific element in another topic. The advantage of using a *conkeyref* is that you can change the element that is included by changing the key reference. For example, since keys are defined in maps, if you include a topic in multiple maps, you can use a different key reference in each map. A *coderef* references an external file that contains literal code.

Oxygen XML Editor provides support for all of these mechanisms.

While the *conref* and *conkeyref* mechanisms can be used to reference any content element, it is considered best practice to only *conref* or *conkeyref* content that is specifically set and managed as reusable content. This practice helps reduce expensive errors, such as an author accidentally deleting the source element that other topics are including by the reference. Oxygen XML Editor can help you create a reusable component from your current content.

Reusing Content with Reusable Components

DITA allows you to select content in a topic, create a reusable component *(on page 3235)* from it and reference that component in other locations. Each reusable component is created as a separate file. Anytime the content needs to be edited, you only need to update it in the component file and all the locations in your topics that reference it will also be updated. This can help you to maintain continuity and accuracy throughout your documents.

Reusing Content with Variables

DITA allows you to replace the content of certain elements with a value that is pointed to by a key. This mechanism effectively means that you can create variables in your content *(on page 3237)*, which you can then create multiple outputs by changing the value that the key points to. This is done by profiling the definition of the key value, or by substituting another map with a different key value.

Reusing Content with DITA 1.3 Concepts

DITA 1.3 allows you to use some advanced concepts to expand content reuse possibilities even further. *Key Scopes* (or scoped keys) *(on page 3239)* allow you to reuse topics with variable content depending on the

particular context and it maximizes reuse possibilities for keys. *Branch Filtering (on page 3241)* allows you to reuse the same content that is profiled in multiple ways within the same publication, each time using a different filter.

DITA Reusable Components View

If you use a large amount of keys or reusable components in your DITA project, the **DITA Reusable Components** view *(on page 3242)* can be quite helpful. It collects all of the keys and reusable components that are defined in the *root map (on page 3424)* and presents them in a dynamic table where you can easily locate and insert references to them.

Reuse Actions in Oxygen XML Editor

Oxygen XML Editor includes some actions that are specifically designed for DITA reusable content. These actions are available in the contextual menu, the **DITA** menu, and some are available on the toolbar.

Reuse Content

This action provides a mechanism for reusing content fragments. It opens the **Reuse Content** dialog box *(on page 3224)* that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include content references (`@conref`) *(on page 3225)*, content key references (`@conkeyref`) *(on page 3227)*, or key references to metadata (`@keyref`) *(on page 3230)*.

Push Current Element

Opens the **Push current element** dialog box *(on page 3233)* that allows content from a source topic to be inserted into another topic without any special coding in the topic where the content will be re-used.

Edit Content Reference

This action is available for elements with a `@conref` or `@conkeyref` attribute. It opens the **Edit Content Reference** dialog box that allows you to edit the source location (or key) and source element of a content reference (or content key reference), and the reference details (`@conref`/`@conkeyref` and `@conrefend` attributes). For more information, see Reuse Content Dialog Box *(on page 3224)*.

Replace Reference with Content

Replaces the referenced fragment (`@conref` or `@conkeyref`) at the cursor position with its content from it source. This action is useful if you want to make changes to the content in the currently edited document without changing the referenced fragment in its source location. If the source content includes references to other topics/resources (*hrefs*), the operation also resolves those references relative to the new location. Attributes are preserved according to the following priority:

1. Attributes from the elements in the current document that reference other content are preserved except for attributes with a `-dita-use-conref-target` value.
2. Attributes from the referenced content are brought into the replaced elements in the current document except for `@id` attributes.

Replace All References with Content

Replaces all referenced fragments (`@keyref`, `@conref`, or `@conkeyref`) in the current document with the content. Attributes are preserved according to the following priority:

1. Attributes from the elements in the current document that reference other content are preserved except for attributes with a `-dita-use-conref-target` value.
2. Attributes from the referenced content are brought into the replaced elements in the current document except for `@id` attributes.

For *keyrefs* inside `<xref>` or `<link>` elements, the `@keyref` attribute is changed to an `@href` attribute, while the rest of the content for the *keyref* is replaced with its source content.

If the source content includes references to other topics/resources (*hrefs*), the operation also resolves those references relative to the new location.

Remove Content Reference

Removes the content reference (`@conref` or `@conkeyref`) inside the element at the cursor position.

Create Reusable Component

Opens a dialog box that helps you to create a reusable component from the current element or selection of elements. If the **Replace selection with content reference** option is selected in the dialog box, the selection will be replaced with a content reference (`@conref`). If multiple elements are selected (for example, multiple steps or list items), the selection will be replaced with a content reference range (`@conref` and `@conrefend`). For more information, see Creating a Reusable Content Component *(on page 3236)*.

Insert Reusable Component

Inserts a reusable component at cursor location. For more information, see Inserting a Reusable Content Component *(on page 3237)*.

Resources

For more information about reusing strategies in DITA, see the following resources:

- **Webinar: Working with DITA in Oxygen - Basic Profiling and Reuse Strategies**
- **Webinar: Working with DITA in Oxygen - Advanced Profiling and Reuse Strategies**

Related information

Working with Keys in DITA *(on page 3207)*

Reusing DITA Topics in Multiple Maps

You can reuse an entire DITA topic simply by referencing it in multiple maps (or multiple locations within the same *map (on page 3096)*) using one of the following procedures:

Reuse Topics Using the DITA Maps Manager

1. Make sure the *DITA map (on page 3419)* is opened in the **DITA Maps Manager** *(on page 3073)*.
2. Add a reference to an existing topic by using one of the following methods (depending on your particular situation):
    a. If the topic already exists in this *DITA map*, do one of the following:
        - Simply drag the topic and press **Ctrl** (or **Alt** on macOS) at the new location within the map (or use the **Copy** and **Paste** contextual menu actions).
        - If the topic is the currently open document in the main editor, determine the new location in the map (in the **DITA Maps Manager** *(on page 3073)*), right-click a parent or sibling topic, and select **Append Child > Reference to the currently edited file** or **Insert After > Reference to the currently edited file**.
    b. If the topic already exists in another *DITA map*, do one of the following:
        - Open the other map in the **DITA Maps Manager** *(on page 3073)*, right-click the topic, select **Copy**, switch back to the original *DITA map* in the **DITA Maps Manager**, determine the new location in the map, right-click a parent or sibling topic, and use one of the **Paste** contextual menu actions (**Paste**, **Paste Before**, or **Paste After**).
        - If the topic is the currently open document in the main editor, determine the new location in the map (in the **DITA Maps Manager** *(on page 3073)*), right-click a parent or sibling topic, and select **Append Child > Reference to the currently edited file** or **Insert After > Reference to the currently edited file**.
    c. If the topic exists in the project, but has not yet been added to a *DITA map*, do one of the following:
        - Right-click the topic in the **Project** view *(on page 413)* (or the file system), select **Copy**, switch to the **DITA Maps Manager** *(on page 3073)* view, determine the new location in the map, right-click a parent or sibling topic, and use one of the **Paste** contextual menu actions (**Paste**, **Paste Before**, or **Paste After**).
        - If the topic is the currently open document in the main editor, determine the new location in the map (in the **DITA Maps Manager** *(on page 3073)*), right-click a parent or sibling topic, and select **Append Child > Reference to the currently edited file** or **Insert After > Reference to the currently edited file**.
3. If your topic uses a key reference *(on page 3207)*, set up the appropriate key definition in your map *(on page 3107)*.
4. If you want to define relationships between topics, other than those defined in the topics themselves, you can add a relationship table to your map *(on page 3260)*.
5. When you have finished adding topics, check that your map is complete and that all topic links and keys resolve correctly. To do this validation, click the **Validate and Check for Completeness** action *(on page 3118)* on the toolbar in the **DITA Maps Manager**.

Reuse Topics Using Author Mode Editor

1. Open the *DITA map (on page 3071)* in the **Author** mode editor.
2. Add a reference to an existing topic by dragging it from the **Project** view *(on page 413)* (or the file system) and dropping it in the desired location in the *DITA map* opened in **Author** mode. You can also accomplish the same thing by using the **Copy** and **Paste** contextual menu actions.
3. If your topic uses a key reference *(on page 3207)*, set up the appropriate key definition in your map *(on page 3107)*.
4. If you want to define relationships between topics, other than those defined in the topics themselves, you can add a relationship table to your map *(on page 3260)*.
5. When you have finished adding topics, check that your map is complete and that all topic links and keys resolve correctly. To do this validation, click the **Validate and Check for Completeness** action *(on page 3118)* on the toolbar in the **DITA Maps Manager**.

Displaying Multiple References to the Same Topics

Whenever multiple references to the same topic are detected in the context of the current map in the **DITA Maps Manager** *(on page 3073)*, an indicator will appear in the top-right corner of the **Author** mode editor that shows the number of times the current topic is referenced in the *DITA map*. It also includes navigation arrows that allow you to jump to the next or previous reference in the **DITA Maps Manager**.

Working with Content References

The DITA *content reference* feature lets you insert a piece of source content by referencing it from its source. When you need to update that content, you only need to do it in one place. The source content can be referenced using the DITA `@conref` or `@conkeyref` attributes.

There are several strategies for managing content references:

- *Reusable components* - With this strategy, you create a new file for each piece of content that you want to reuse and you insert references from the content of the reusable component files. For example, suppose that you have a disclaimer that needs to be included in certain sections of your documentation. You can create a reusable component that contains your disclaimer and reuse it as often as you need to. If the disclaimer ever needed to be updated, you only have to edit it in one file.
- *Single-source content references* - You may prefer to keep many pieces of reusable content in one file. For example, you might want to create a single file that contains all the actions that are available in various menus or toolbars for your software application. Then, wherever you need to describe or display an action in your documentation, you can reuse content from that single file by inserting content references. This strategy requires more setup than reusable components, but might make it easier to centrally managing the reused content and it allows for more flexibility in the XML structure of the reusable content.

- *Arbitrary content references* - Although it is not recommended, you can create content references among topics without storing the reusable content in components or a single file. This strategy might make it difficult to manage content that is reused and to maintain continuity and accuracy, since you may not have any indication that content you are editing is reused elsewhere.

A reference to the external content is created by adding a `@conref` or `@conkeyref` attribute to an element in the local document. The `@conref` or `@conkeyref` attribute defines a link to the referenced content, made up of a path to the file and the topic ID within the file. The path may also reference a specific element ID within the topic. Referenced content is not physically copied to the referencing file. However, by default, Oxygen XML Editor displays it in **Author** mode as if it is there in the referencing file. If you want to expand referenced content on demand (rather than having it be automatically expanded), open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)*, go to **Editor > Edit modes > Author**, and deselect the **Display referenced content** option *(on page 186)*.

Note:
A reference also displays *tracked changes (on page 3424)* and comments that are included in the source fragment. To edit these comments (or accept/reject changes) right-click the comment or tracked change and select **Edit Reference**.

Tip:
To search for references made through a direct content reference, use the **Search References** action from the contextual menu.

Creating a DITA Content Reference

DITA Content Reference

A DITA content reference, or `conref`, is one of the main content *reuse* features of DITA *(on page 3212)*. It is a mechanism for re-using the same content in multiple topics (or even in multiple locations within the same topic).

For a `conref` to be created, the source content must have an `id` attribute that the `conref` can reference. Therefore, creating a `conref` requires that you add an `id` to the content to be reused before inserting a `conref` into the topic that reuses the referenced content.

Assigning an *ID* to the Referenced Content

To add an `id` to a DITA element in a topic, place the cursor on the element and select **Edit Attributes** from the contextual menu (or simply press **Alt+Enter**) to open the in-place attribute editor *(on page 640)*. Enter `id` as the **Name** of the attribute and a value of your choice in the **Value** field. You can also use the **Attributes** view *(on page 638)* to enter a value in the **id** attribute.

Note:
The element may already have an `id`, since in some cases, Oxygen XML Editor automatically generates an *ID* value when the `id` attribute is created.

Creating a Content Reference

To create a content reference (`conref`), follow these steps:

1. Make sure the element you want to reference has an *ID* assigned to it *(on page 3218)*.
2. In **Author** mode *(on page 363)*, place the cursor at the location where you want the reused content to be inserted.
3. Select the **Reuse Content** action on the main toolbar (or from the **DITA** menu or **Reuse** submenu of the contextual menu). The **Reuse Content** dialog box *(on page 3224)* is displayed.
4. In the **Location** field of the **Reuse Content** dialog box, select the topic that contains the element you want to reference. The elements that you can reference are presented in a table.
5. Select the **Target ID** of the element (or elements) to have their content inserted, and verify the content in the **Preview** pane. The `id` value of the element that you select is automatically added to the **Reference to (conref)** field.
6. Make any other selections you need in the **Reuse Content** dialog box *(on page 3224)*. If you select multiple elements, the **Expand to (conrefend)** field is automatically filled with the `id` value of the last element in your selection.
7. Click **Insert** or **Insert and close** to create the content reference.

Using Copy/Paste Actions to Create a Content Reference

Oxygen XML Editor also includes support for creating content references with simple copy/paste actions. The copied content must be an entire DITA XML element with an ID attribute. Also, the location in the document where you paste the element must be valid, although as long as the **Smart paste and drag and drop** option *(on page 189)* is selected in the **Schema-Aware** preferences page, if you try to paste it in an invalid location, Oxygen XML Editor will attempt to place it in a valid location, and may prompt you with one or more choices for where to place it.

To create a content reference (`conref`) using copy/paste actions, follow these steps:

1. Copy an entire DITA element that has an ID attribute assigned to it.
2. Place the cursor at a location where the copied element will be valid.
3. Select the **Paste as Content Reference** action from the  **Paste Special** submenu from the contextual menu.

Other Ways to Reuse Content

- You can use the **Components** tab in the **DITA Reusable Components** view *(on page 3247)* to easily insert content references.
- An alternate way to reuse content is to use the Oxygen XML Editor **Create Reusable Component** *(on page 3236)* and **Insert Reusable Component** *(on page 3237)* actions (available in the **DITA** menu and the **Reuse** submenu of the contextual menu). They handle the details of creating an *ID* and *conref* and create reusable component files, separate from your normal content files. This can help you manage your reusable content more effectively.
- You can also insert reusable content using content key references *(on page 3219)*. This may also make reusable content easier to manage, depending on your particular situation and needs.
- Other topics in this section include information about more specialized or advanced ways or reusing content, such as *code references (on page 3232)*, the *conref push mechanism (on page 3233)*, *variable text (on page 3237)*, *key scopes (on page 3239)*, and *branch filtering (on page 3241)*.

Working with Content References *(on page 3216)*

Creating a DITA Content Key Reference

DITA Content Key Reference

A DITA content key reference, or `@conkeyref`, is a mechanism for inserting a piece of content from one topic into another. It is a version of the DITA content reference mechanism *(on page 3217)* that uses keys *(on page 3207)* to locate the content to reuse rather than direct references to topics that contain reused content.

As with a *conref*, a *conkeyref* requires that the element to be reused has an `@id` attribute. It also requires the topic that contains the reusable content to be assigned a key *(on page 3207)* in a map. As with all uses of keys, you can substitute multiple maps or use profiling *(on page 3319)* to create multiple definitions of keys in a single map. This allows the same `@conkeyref` to pull in content from various sources, depending on how your build is configured. This can make it easier to create and manage sophisticated content reuse scenarios.

Creating a Content Key Reference

To create a content key reference (`@conkeyref`), follow these steps:

1. Make sure the topic that contains the reusable content is assigned a key in the *DITA map* and the element you want to reference has an *ID* assigned to it.
2. In **Author** mode *(on page 363)*, place the cursor at the location where you want the reused content to be inserted.
3. Select **Reuse Content** on the main toolbar (or from the **DITA** menu or **Reuse** submenu of the contextual menu). The **Reuse Content** dialog box *(on page 3224)* is displayed.
4. Select the **Key** radio button for the content source and use the **Choose Key Reference** button to select the key for the topic that contains the reusable content (you can also select one from the drop-down list in the **Key** field). The elements that you can reference from the source are presented in the table in the middle of the **Reuse Content** dialog box.
5. Select the **Target ID** of the element (or elements) that you want to insert, and verify the content in the **Preview** pane. The `@id` value of the element that you select is automatically added to the **Reference to (conkeyref)** field.
6. Make any other selections you need in the **Reuse Content** dialog box *(on page 3227)*. If you select multiple elements, the **Expand to (conrefend)** field is automatically filled with the `@id` value of the last element in your selection.
7. Click **Insert** or **Insert and close** to create the content reference.

Note:
If you are using **Text** mode *(on page 362)*, when you insert a `@conkeyref` attribute, after you enter the first quote (`conkeyref="`), the **Content Completion Assistant** will list all the defined keys that you can select from. Also, after you select the key, the **Content Completion Assistant** will then list the element IDs from the referenced topic, allowing you to insert an anchor. Note that this only works for local files.

Using Copy/Paste Actions to Create a Content Key Reference

Oxygen XML Editor also includes support for creating content key references with simple copy/paste actions. When the DITA content is processed, the key references are resolved using key definitions from *DITA maps*. The copied content must be an entire DITA XML element with an ID attribute and the topic that contains the reusable content must have a key assigned in a *DITA map*. Also, the location in the document where you paste the element must be valid, although as long as the **Smart paste and drag and drop** option *(on page 189)* is selected in the **Schema-Aware** preferences page, if you try to paste it in an invalid location, Oxygen XML Editor will attempt to place it in a valid location, and may prompt you with one or more choices for where to place it.

To create a content key reference (`@conkeyref`) using copy/paste actions, follow these steps:

1. In the **DITA Maps Manager** view *(on page 3073)*, make sure that the **Context** combo box *(on page 3077)* points to the correct map that stores the keys.
2. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager** *(on page 3073)*, select **Edit Properties**, and enter a value in the **Keys** field.
3. In a topic with an assigned key, copy an entire DITA element that has an ID attribute assigned to it.
4. Place the cursor at a location where the copied element will be valid.
5. Select the **Paste as Content Key Reference** action from the  **Paste Special** submenu from the contextual menu.

Other Ways to Reuse Content

- You can use the **Components** tab in the **DITA Reusable Components** view *(on page 3247)* to easily insert content key references.
- You can also insert reusable content using content references (*conref) (on page 3217)*.
- Other topics in this section include information about more specialized or advanced ways or reusing content, such as *code references (on page 3232)*, the *conref push mechanism (on page 3233)*, *variable text (on page 3237)*, *key scopes (on page 3239)*, and *branch filtering (on page 3241)*.

Related Information:

Creating a DITA Content Reference *(on page 3217)*
Editing DITA Content References *(on page 3221)*
Working with Reusable Components *(on page 3235)*
Working with Content References *(on page 3216)*

Editing DITA Content References

When you reference reusable content using a `@conref` or `@conkeyref` attribute, by default, the content is grayed out in the document and can only be edited from the source document. To edit the source of the referenced content, click the  icon at the beginning of the inserted content. This will open the source document where you can edit the referenced content.

Oxygen XML Editor also includes some actions that allow you to quickly edit existing content references. When the element that contains a content reference (`@conref` or `@conkeyref`) is selected, the following actions are available in the **DITA** menu and the **Reuse** submenu of the contextual menu:

Edit Content Reference

This action is available for elements with a `@conref` or `@conkeyref` attribute. It opens the **Edit Content Reference** dialog box that allows you to edit the source location (or key) and source element of a content reference (or content key reference), and the reference details (`@conref`/`@conkeyref` and `@conrefend` attributes). For more information, see Reuse Content Dialog Box *(on page 3224)*.

Replace Reference with Content

Replaces the referenced fragment (`@conref` or `@conkeyref`) at the cursor position with its content from it source. This action is useful if you want to make changes to the content in the currently edited document without changing the referenced fragment in its source location. If the source content includes references to other topics/resources (*hrefs*), the operation also resolves those references relative to the new location. Attributes are preserved according to the following priority:

1. Attributes from the elements in the current document that reference other content are preserved except for attributes with a `-dita-use-conref-target` value.
2. Attributes from the referenced content are brought into the replaced elements in the current document except for `@id` attributes.

Replace All References with Content

Replaces all referenced fragments (`@keyref`, `@conref`, or `@conkeyref`) in the current document with the content. Attributes are preserved according to the following priority:

1. Attributes from the elements in the current document that reference other content are preserved except for attributes with a `-dita-use-conref-target` value.
2. Attributes from the referenced content are brought into the replaced elements in the current document except for `@id` attributes.

For *keyrefs* inside `<xref>` or `<link>` elements, the `@keyref` attribute is changed to an `@href` attribute, while the rest of the content for the *keyref* is replaced with its source content.

If the source content includes references to other topics/resources (*hrefs*), the operation also resolves those references relative to the new location.

Remove Content Reference

Removes the content reference (`@conref` or `@conkeyref`) inside the element at the cursor position.

Converting Conrefs to Conkeyrefs

Oxygen XML Editor includes a DITA refactoring operation called **Convert conrefs to conkeyrefs** that will find all *content references* (that reference content outside the current document) and convert them to *content key references*. You can also use it to quickly convert all *content references* in the current document or multiple documents at once.

To access the **Convert conrefs to conkeyrefs** operation, use one of the following methods:

Single Document Method

With the document opened in the editor, right-click anywhere in the main editing pane (or right-click the topic reference in the **DITA Maps Manager** *(on page 3073)*), go to the **Refactoring** submenu, and choose **Convert conrefs to conkeyrefs**.

Multiple Documents At Once Method

Select **XML Refactoring** from the **Tools** menu (or from the **Refactoring** submenu when you right-click a document in the **Project** view *(on page 413)*or the **DITA Maps Manager** view *(on page 3073)*). Then select **Convert conrefs to conkeyrefs** from the **DITA** section and click **Next**.

Either method will proceed to the **XML Refactoring Wizard**. If you used the **Multiple Documents At Once Method** *(on page 3223)*, the wizard page allows you to choose a scope for the operation and some filtering options:

- **Scope** - Select from a variety of options to define the scope that will have resources affected by the operation. For example, you can choose to affect all resources in the **Project**, **All opened files**, **Current DITA map hierarchy**, or just the **Current file**.
- **Filters** section
  - **Include files** - Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as ***** or **?**).
  - **Restrict to known XML file types only** - Excludes non-XML file types from the operation.
  - **Look inside archives** - If this option is selected, the scope of the operation will include files inside archives.

If you used the **Single Document Method** *(on page 3222)*, the scope will be the current file so the scope and filtering options are not displayed.

You can then use one of the following buttons to proceed with the operation:

Preview

You can use the **Preview** button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

Warning:
It is always recommended to use the **Preview** button to make sure the operation is not going to do something unexpected and after you click the **Finish** button, any **Undo** action will only revert changes on the current document.

Finish

When you use the **Finish** button, the operation will be processed and all *content references* will be converted to *content key references* (either all *content references* in the current document or all *content references* in all of the documents specified in the scope). The file name for each converted document is used as the value for its new key. However, the operation does NOT automatically add the key to the *DITA Map (on page 3419)*, so you still need to manually define each key in your *DITA map (on page 3107)*.

Related Information:

Creating a DITA Content Reference *(on page 3217)*

Creating a DITA Content Key Reference *(on page 3219)*

Defining Keys in DITA Maps *(on page 3107)*

Reuse Content Dialog Box

The **Reuse Content** dialog box provides a mechanism for reusing content fragments. DITA `@conref`, `@conkeyref`, and `@keyref` attributes can be used to insert references to reusable content. The `@conref` attribute stores a reference to another element and is processed to replace the referencing element with the referenced element. The `@conkeyref` attribute uses keys *(on page 3207)* to locate the content to reuse rather than direct references to the topic that contains the reusable content. The `@keyref` attribute also uses keys *(on page 3207)* and can be used to indirectly reference metadata that may have different values in various circumstances.

Note:
For a *conref* or *conkeyref*, to reference the content inside a DITA element, the source element must have an `@id` attribute assigned to it. The element containing the content reference acts as a placeholder for the referenced element. For more details about DITA `@conref` and `@conkeyref` attributes, go to https://www.oxygenxml.com/dita/1.3/specs/archSpec/base/conref.html.

Note:
For the purposes of using a `@keyref`, keys are defined at map level and referenced afterward. For more information about the DITA `@keyref` attribute, go to https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/thekeyrefattribute.html.

Oxygen XML Editor displays the referenced content *(on page 605)* of a DITA content reference if it can resolve it to a valid resource. If you use URIs instead of local paths in your XML documents and your DITA-OT transformation needs an *XML Catalog (on page 3425)* to map the URIs to local paths, you need to add the catalog in Oxygen XML Editor *(on page 838)*. If the URIs can be resolved, the referenced content is displayed in **Author** mode and in the transformation output.

In **Author** mode, a reference to reusable content (`@conref`, `@conkeyref`, or `@keyref`) can easily be inserted at the cursor position by using the **Reuse Content** dialog box. It can be opened with any of the following methods:

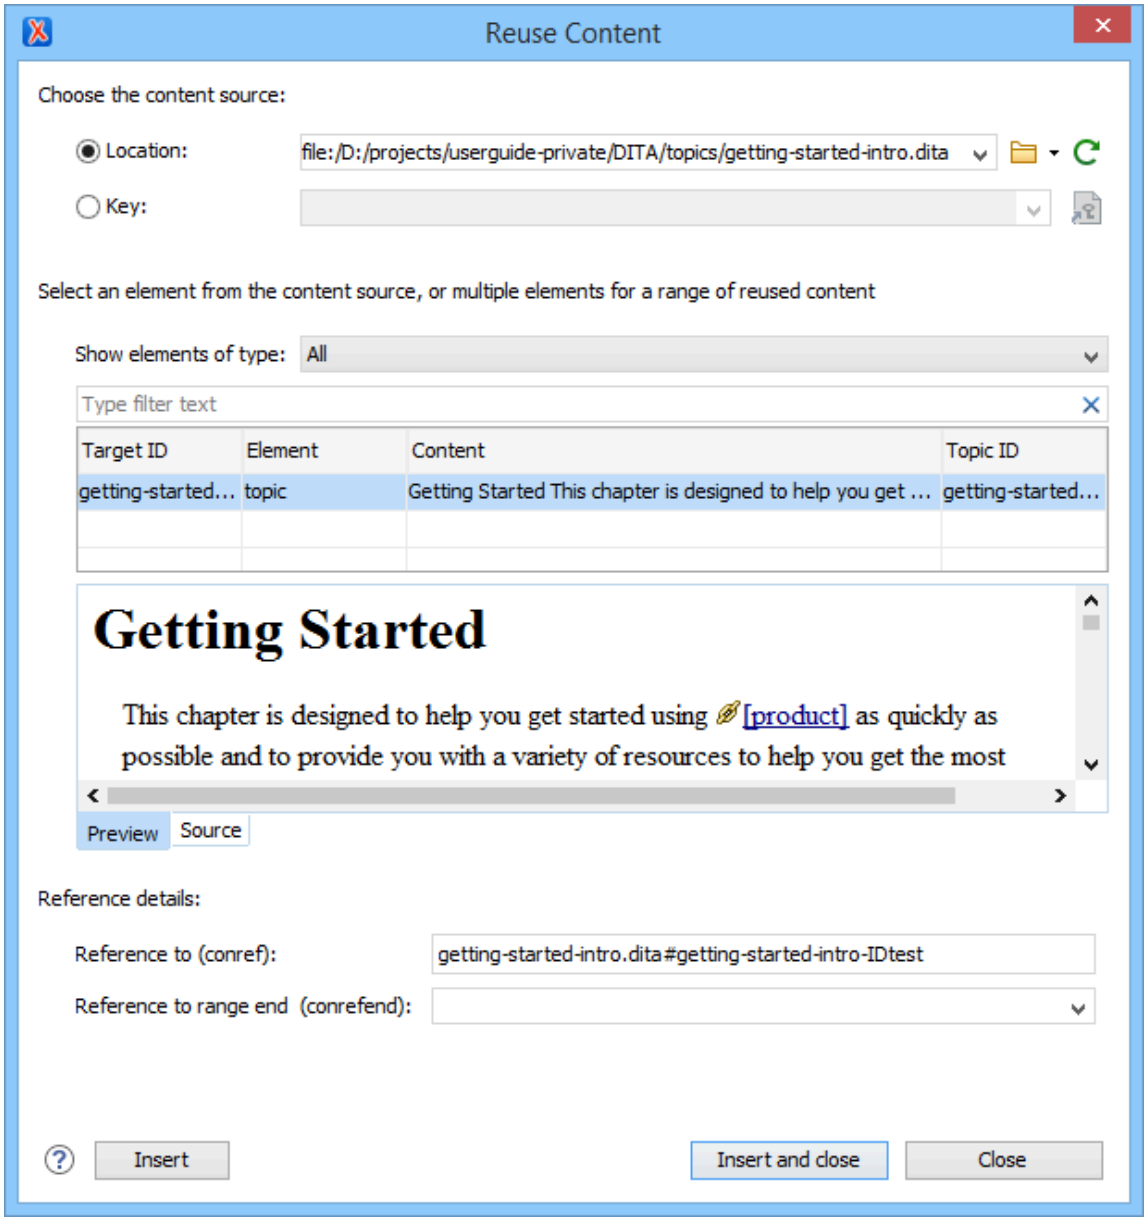
- Click the **Reuse Content** action on the main toolbar.
- In the contextual menu of the editing area, go to **Reuse >** **Reuse Content**.
- Go to **DITA >** **Reuse Content**.

Your selection at the top of the dialog box for choosing the content source determines whether Oxygen XML Editor will insert a `@conref`, `@conkeyref`, or `@keyref`.

If you select **Location** for the content source, a *content reference* (`@conref`) will be inserted. If you select **Key** for the content source, keys will be used to insert a *content key reference* (`@conkeyref`) or a *key reference* (`@keyref`).

Content Reference (`@conref`) Options Using the Reuse Content Dialog Box

Figure 801. Reuse Content Dialog Box (with the Default Insert Content Reference Options Displayed)



Choose the content source Section

When **Location** is selected for the content source, a *content reference* (`@conref`) will be inserted. Here you can specify the path of the topic that contains the content you want to reference.

The dialog box offers the following options:

Select an element from the content source Section

Show elements of type

You can use this drop-down list to select specific types of elements to be displayed in the subsequent table. This can help you narrow down the list of possible source elements that you can select.

Text Filter Field

You can also use the text filter field to narrow down the list of possible source elements to be displayed in the subsequent table.

Element Table

Presents all the element IDs defined in the source topic. Use this table to select the **Target ID** of the element that you want to reference. You can select multiple contiguous elements to reference a block of content.

Preview Pane

Displays the content that will be references. If you select multiple elements in the element table, the content from all the selected elements is displayed.

Source Pane

Displays the source code of the element to be referenced.

Reference details Section

Reference to (conref)

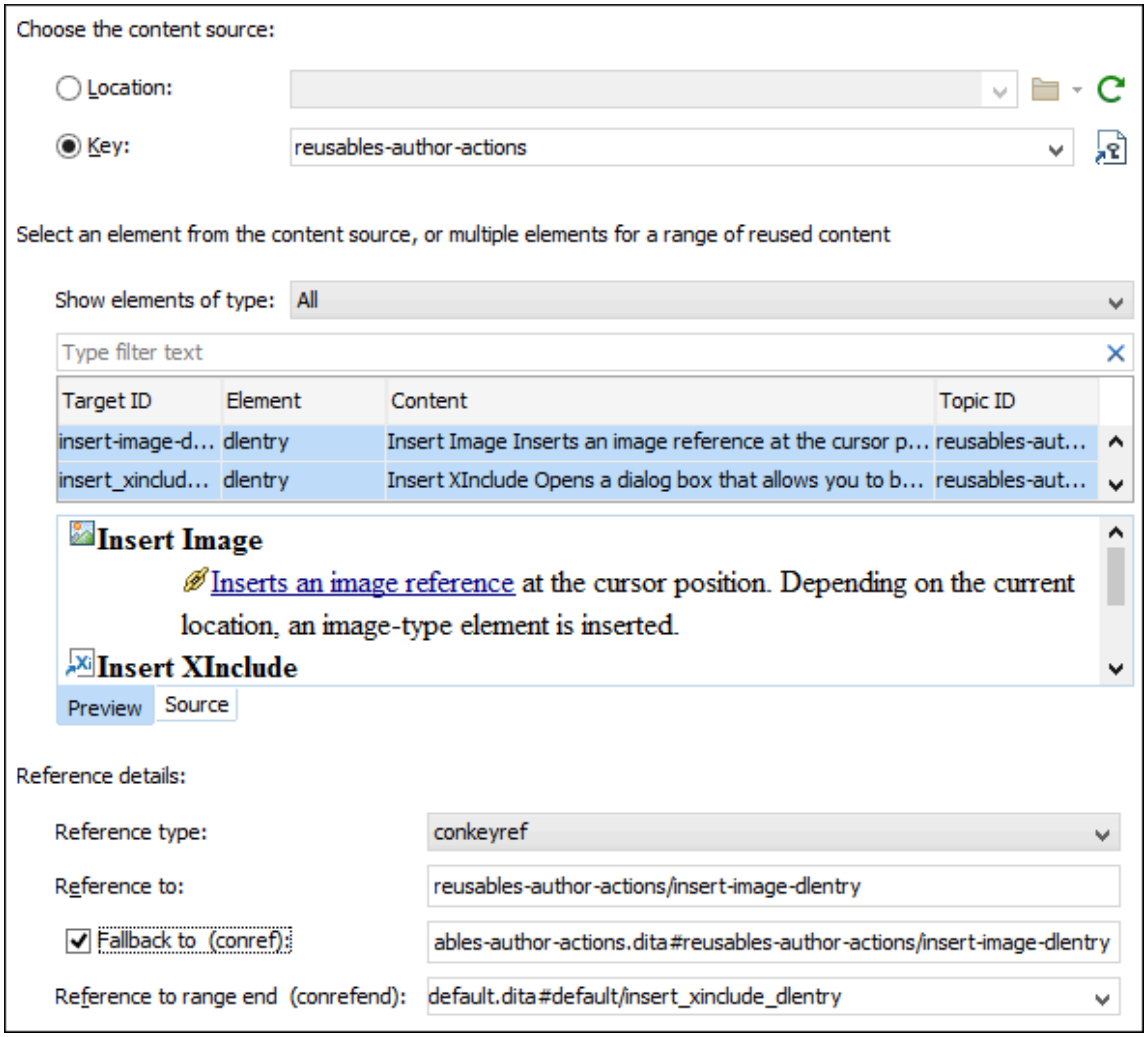
Oxygen XML Editor automatically fills this text field with the value of the `@conref` attribute to be inserted. However, you can edit this value if need be.

Reference to range end (conrefend)

If you select multiple elements (of the same type) in the element table, Oxygen XML Editor automatically fills this text field with the `@id` value of the last element in your selection. This value will be inserted as a `@conrefend` attribute, defining the end of the *conref* range.

Content Key Reference (`@conkeyref`) Options Using the Reuse Content Dialog Box

Figure 802. Insert Content Key Reference Options



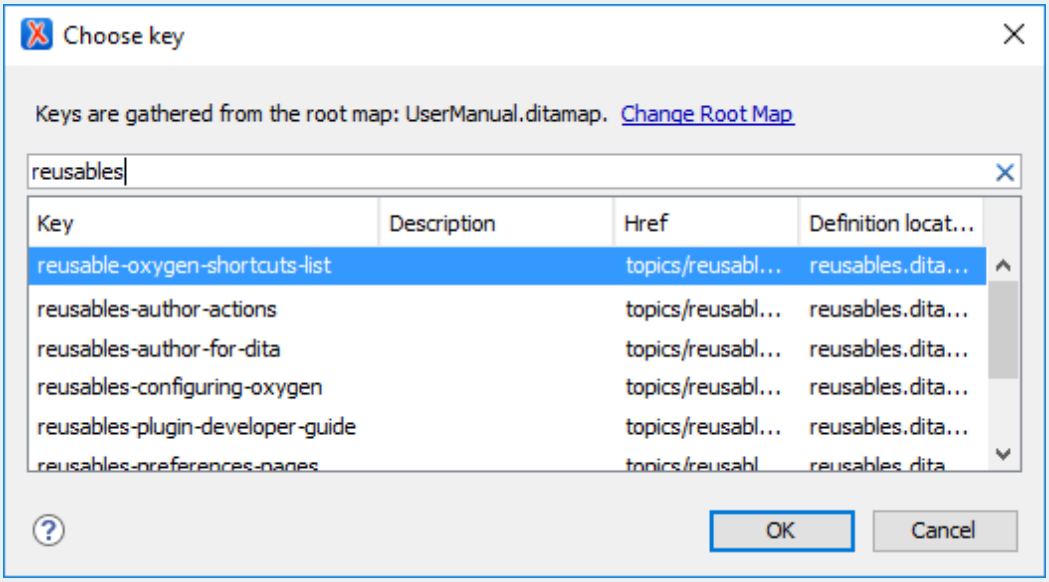
Choose the content source Section

When **Key** is selected for the content source, you can use keys to reference content. You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that allows you to select one from a list of all the keys that are gathered from the *root map (on page 3424)* (you can also select one from the drop-down list in the **Key** field).

Note:
If the current *DITA map* is not selected as the *root map*, no keys will be listed.

Tip:
You can also use the **DITA Reusable Components** view *(on page 3242)* for similar purposes.

Figure 803. Choose Key Dialog Box



The **Choose Key** dialog box includes the following:

- **Change Root Map** - Opens a small dialog box that allows you to select a *root map (on page 3090)*.
- **Search Filter** - You can enter text in the filter field at the top of the dialog box to filter the list and search for a specific key.
- **Sortable Columns** - The dialog box includes the following columns that can be sorted by clicking on the heading:
  - **Key** - The name of the key (the value of the `@keys` attribute).
  - **Description** - The description of the key that is obtained from its definition. Keys that are defined with a text value in the `<navtitle>` or `<keyword>` element have that value listed in this column.
  - **Href** - Keys that are defined with a value in an *href* attribute have that href value listed in this column.
  - **Definition Location** - The name of the *DITA map (on page 3419)* where the key is defined.
- **Group by Definition Location** - A contextual menu action that can be used to group (and sort) all the keys based upon the value in the **Definition Location** column.

To insert a *content key reference* (`@conkeyref`), select the key that contains the content you want to reference. Notice that the file path is shown in the **Href** column. Keys that do not have a value in the **Href** column are for referencing metadata with a `@keyref` attribute. Therefore, to insert a `@conkeyref`, you need to select a key that does have a value (file path) in the **Href** column.

After you select a key, click **OK** to return to the **Reuse Content** dialog box.

When a key that is defined as a *content key reference* has been selected, the **Reuse Content** dialog box offers the following additional options for inserting a `@conkeyref`:

Select an element from the content source Section

Show elements of type

You can use this drop-down list to select specific types of elements to be displayed in the subsequent table. This can help you narrow down the list of possible source elements that you can select.

Text Filter Field

You can also use the text filter field to narrow down the list of possible source elements to be displayed in the subsequent table.

Element Table

Presents all the element IDs defined in the source topic. Use this table to select the **Target ID** of the element that you want to reference. You can select multiple contiguous elements to reference a block of content.

Preview Pane

Displays the content that will be references. If you select multiple elements in the element table, the content from all the selected elements is displayed.

Source Pane

Displays the source code of the element to be referenced.

Reference details Section

Reference type

The type of reference that will be inserted. If you selected a key that references a DITA resource, you will notice that **conkeyref** value is automatically selected.

Reference to

Oxygen XML Editor automatically fills this text field with the value of the `@conkeyref` attribute to be inserted. However, you can edit this value if need be.

Fallback to (conref)

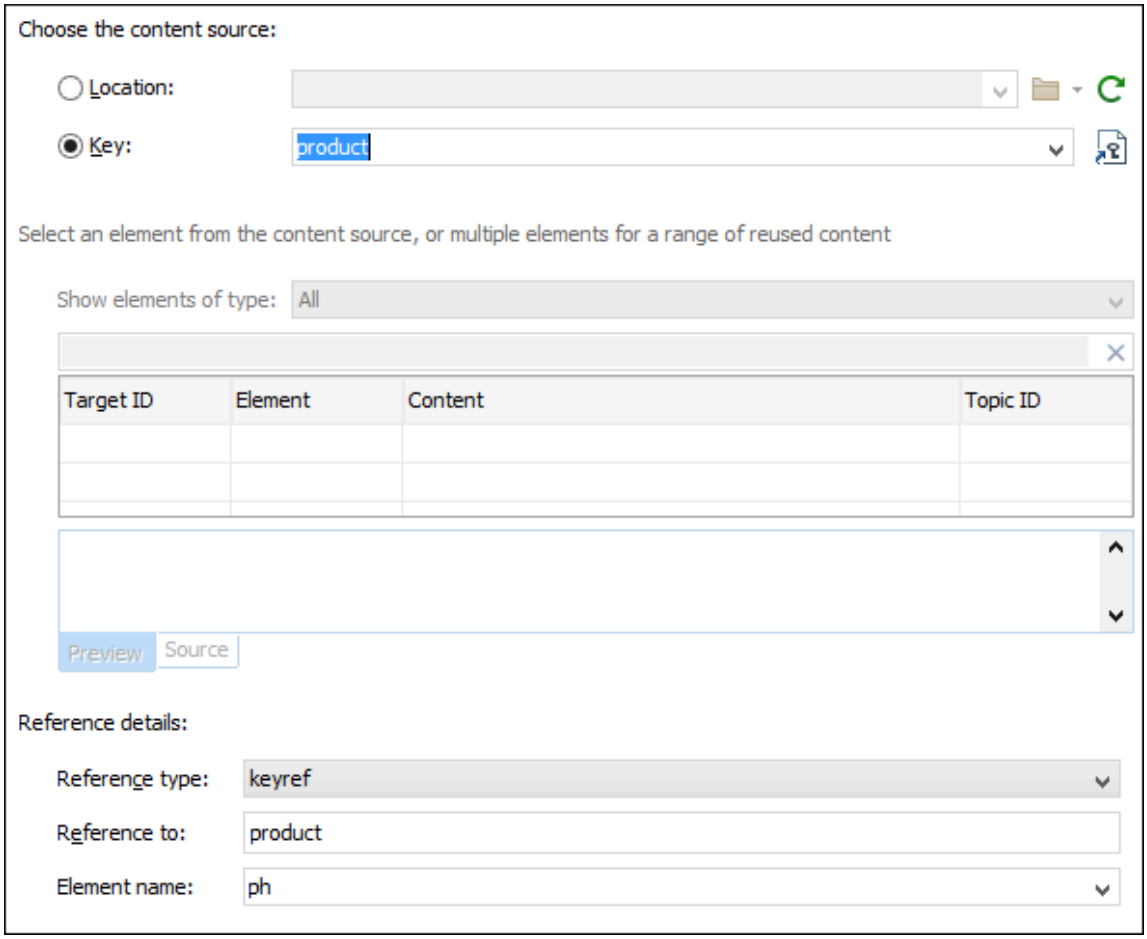
You can select this option to define a `@conref` attribute to be used as a fallback to determine the content reference relationship if the specified *conkeyref* cannot be resolved.

Reference to range end (conrefend)

If you select multiple elements (of the same type) in the element table, Oxygen XML Editor automatically fills this text field with the `@id` value of the last element in your selection. This value will be inserted as a `@conrefend` attribute, defining the end of the *conkeyref* range.

Key Reference to Metadata (`@keyref`) Options Using the Reuse Content Dialog Box

Figure 804. Insert Key Reference Options



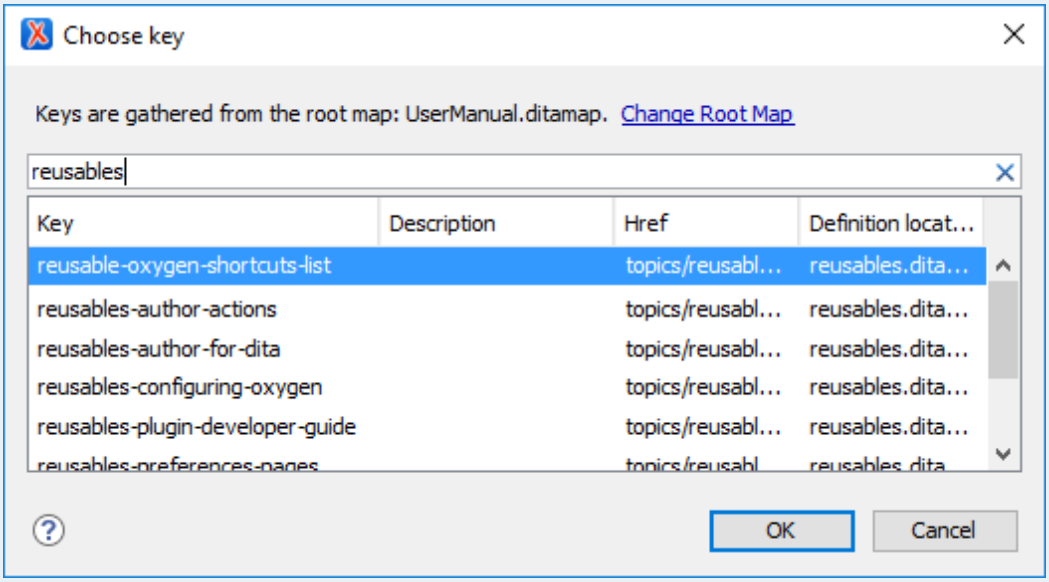
Choose the content source Section

When **Key** is selected for the content source, you can use keys to reference content. You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that allows you to select one from a list of all the keys that are gathered from the *root map (on page 3424)* (you can also select one from the drop-down list in the **Key** field).

Note:
If the current *DITA map* is not selected as the *root map*, no keys will be listed.

Tip:
You can also use the **DITA Reusable Components** view *(on page 3242)* for similar purposes.

Figure 805. Choose Key Dialog Box



The **Choose Key** dialog box includes the following:

- **Change Root Map** - Opens a small dialog box that allows you to select a *root map (on page 3090)*.
- **Search Filter** - You can enter text in the filter field at the top of the dialog box to filter the list and search for a specific key.
- **Sortable Columns** - The dialog box includes the following columns that can be sorted by clicking on the heading:
  - **Key** - The name of the key (the value of the `@keys` attribute).
  - **Description** - The description of the key that is obtained from its definition. Keys that are defined with a text value in the `<navtitle>` or `<keyword>` element have that value listed in this column.
  - **Href** - Keys that are defined with a value in an *href* attribute have that href value listed in this column.
  - **Definition Location** - The name of the *DITA map (on page 3419)* where the key is defined.
- **Group by Definition Location** - A contextual menu action that can be used to group (and sort) all the keys based upon the value in the **Definition Location** column.

To insert a *key reference* to metadata (`@keyref`), select the key you want to reference. Keys that do not have a value in the **Href** column are for referencing metadata with a `@keyref` attribute. Therefore, to insert a `@keyref`, you need to select a key that does not have a value (file path) in the **Href** column.

After you select a key, click **OK** to return to the **Reuse Content** dialog box.

When a key that references metadata has been selected, the **Reuse Content** dialog box offers the following additional options for inserting a `@keyref`:

Select an element from the content source Section

This section is not used when referencing metadata.

Reference details Section

Reference type

The type of reference that will be inserted. If you selected a key that does not reference a DITA resource, you will notice that **keyref** value is automatically selected.

Reference to

Oxygen XML Editor automatically fills this text field with the value of the `@keyref` attribute to be inserted.

Element name

Oxygen XML Editor automatically selects the element that is most commonly used for the selected type of key reference, but you can use the drop-down list to choose another element to use for the reference.

Finalizing Your Content Reference Configuration

Once you click **Insert** or **Insert and close**, the configured content reference is inserted into your document.

Tip:
You can easily insert multiple content references by keeping the **Reuse Content** dialog box opened, using the **Insert** button.

DITA Reusable Components View *(on page 3242)*
Working with Content References *(on page 3216)*

Working with Code References

Code References

The DITA `<coderef>` element can be used to reference an external file that contains literal code. This is especially useful if you need to reference code from an external source that may occasionally change. Another advantage is that you don't have to convert illegal characters into their character equivalents. When the `<coderef>` is processed, the referenced code file is imported and delimiting characters (such as `<` or `&`) are displayed as standard text, rather than treated as XML markup.

For more information about code references, see DITA 1.3 Specification: Coderef.

Example of using a Coderef

```
<p>This code is an example of how to use a coderef.</p>
  <codeblock><coderef href="MyExternalCode.xsl"/></codeblock>
```

Defining Line Ranges

DITA-OT provides additional code reference processing support that allows you to define line ranges in case you only want to reference certain parts of the external file, rather than the whole file.

For information and examples of how to define line ranges, see DITA Open Toolkit Documentation: Extended Code Reference Processing.

Working with the Conref Push Mechanism

Content Reference Push Mechanism

The usual method of using content references pulls element content from a source element and inserts it in the current topic. DITA 1.2 introduced an alternative method of content referencing, allowing element content to be pushed, or injected, from a source topic to another topic without any special coding in the topic where the content will be re-used. This technique is known as a content reference *push* mechanism (*conref push*).

The *conref push* mechanism requires elements in the target topic (the topic where the content is to be pushed) to have ID elements, as the push mechanism inserts elements *before* or *after* a named element, or *replaces* the named element. Assuming the source topic is included in the *DITA map (on page 3419)*, the *conref push* will be processed during the publishing stage for the *DITA map*.

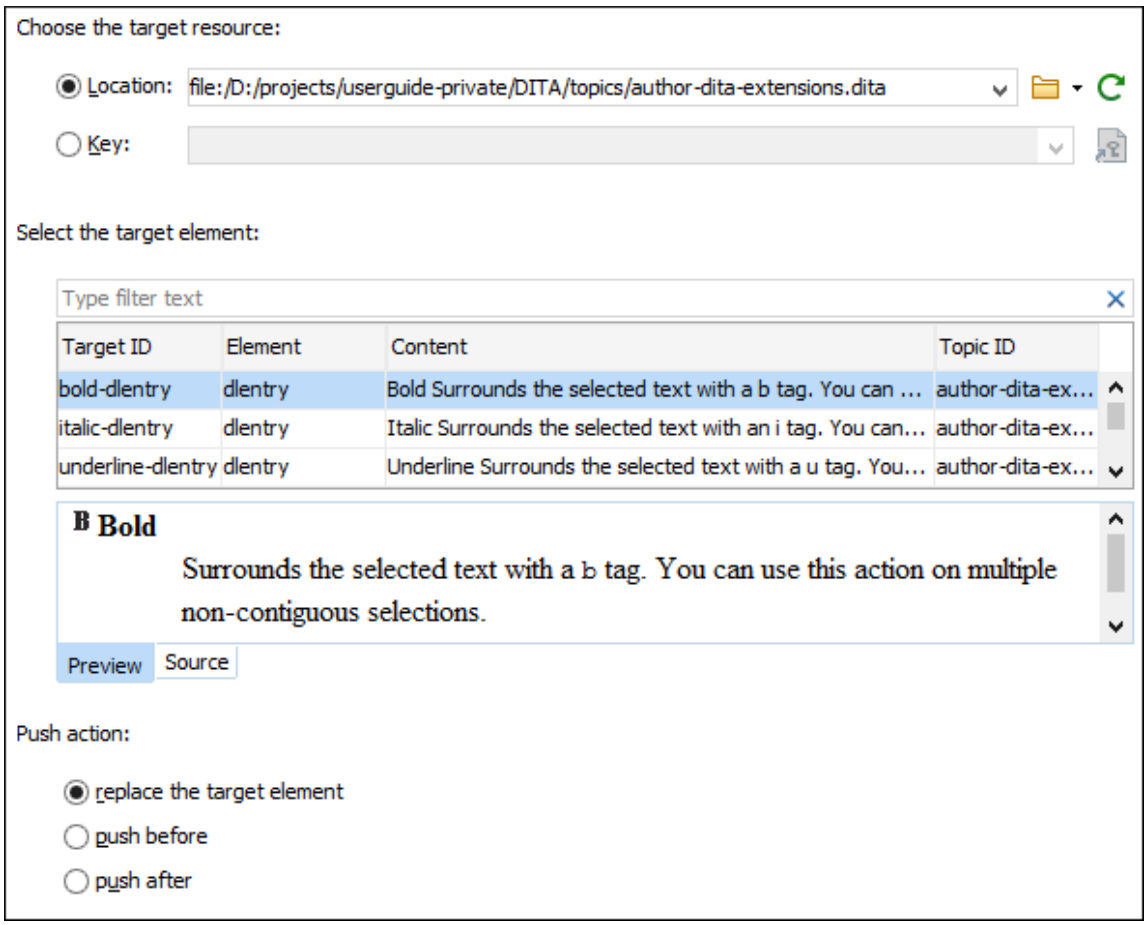
Example of a Conref Push Scenario

An example of a scenario where a *conref push* would be useful is where a car manufacturer produces driver manuals that are distributed to various regions with their own specific regulations and certain sections need to be customized by the local car dealers before publishing. The local dealer could use a *conref push* technique to insert specific content without modifying the manufacturer-supplied content.

Push Current Element Action

Oxygen XML Editor includes an action that allows you to easily reference content with a *conref push* mechanism. The **Push Current Element** action is available in the **DITA** menu and in the **Reuse** subfolder of the contextual menu when editing in **Author** mode. Selecting this action opens the **Push current element** dialog box that allows you to select a target resource and element, and where to insert the current element content.

Figure 806. Push Current Element Dialog Box



This dialog box allows you to configure the following options for the *conref push* action:

Choose the target resource

Allows you to select a **Location** URL or a **Key** for the target resource and the table in the next section of the dialog box will be populated using the information from the specified resource.

Select the target element

The table in this section contains the available elements (identified by their ID) that can be replaced by, or pushed before/after, the current element, according to the push action.

Push action

Allows you to choose one of the following options for where you want to insert the current element content:

replace the target element

The target element will be replaced with the current element content.

On the technical side, the value of the `@conaction` attribute in the current element will be set to `push replace` and the `@conref` or `@conkeyref` attribute will be set to the specified reference.

push before

The current element content will be inserted before the specified target element in the target resource.

On the technical side, the value of the `@conaction` attribute in the current element will be set to `pushbefore`. Another element with the same name and class as the target element will be inserted in the document after the current element. The new element will have the `@conaction` attribute set to `mark` and the `@conref` or `@conkeyref` attribute will be set to the specified reference.

push after

The current element content will be inserted after the specified target element in the target resource.

On the technical side, the value of the `@conaction` attribute in the current element will be set to `pushafter`. Another element with the same name and class as the target element will be inserted in the document before the current element. The new element will have the `@conaction` attribute set to `mark` and the `@conref` or `@conkeyref` attribute will be set to the specified reference.

You can also use the **Preview** panel to view the content that will be pushed and the **Source** panel to see the XML code for the content to be pushed. After you click **OK**, the *conref push* mechanism is inserted in the current document. The changes in the target resource will be processed when you transform the *DITA map*.

Doctales - Content Reference Push

Working with Reusable Components

In DITA, the content of almost any element can be made reusable simply by adding an `@id` attribute to the element. The DITA content reference mechanism can reuse any element with an *ID*. However, it is not considered best practice to arbitrarily reuse pieces of text from random topics due to the difficulties this creates in trying to manage it. It also creates the possibility of authors deleting or changing content that is reused in other topics without being aware that the content is reused.

To prevent these types of problems, you can create reusable components to manage a separate set of topics that contain topics designed specifically for reuse. Then, all of your reusable content can be referenced from the reusable components and if the content needs to be updated you only need to edit it in one place.

Oxygen XML Editor allows you to select content in a topic, create a reusable component from it and reference that component in other locations by using the **Create Reusable Component** *(on page 3236)* and **Insert Reusable Component** *(on page 3237)* actions.

Related Information:

DITA Reusable Components View *(on page 3242)*

Creating a Reusable Content Component

Oxygen XML Editor makes it easy to create a reusable component from existing topic content.

Note:
To ensure that the topic file that contains the reusable component is a valid container for the reusable content component, Oxygen XML Editor attempts to use the same schema information in the current topic for the file that contains the reused component. If it cannot create a valid instance of the reused content file with this approach, the application creates a specialized topic type automatically. This specialization is designed to make sure that the content is compatible with the topic type that it is created from. You can make changes to the configuration file (`OXYGEN_INSTALL_DIR\frameworks\dita\reuse\reuse_configuration.properties`) or override it from a framework extension to control if the created reusable component file should be based on the currently edited topic or it should be an automatically created DITA specialization topic.

Follow these steps to create a reusable component:

1. In **Author** mode, select the content you want to make into a reusable component (or place the cursor inside an element you want to reuse).
2. Select the **Create Reusable Component** action that is available in the **DITA** menu or the **Reuse** submenu of the contextual menu.
   The **Create Reusable Component** dialog box is displayed.
3. Use the **Reuse Content** drop-down list to select the scope of the content to be made reusable. It allows you to select how much of the current content you want to make reusable. The choices presented include the element at the current cursor position and its ancestor elements.
4. Add a description. This is used as a description for the reusable component, but is not part of the reused content. It is just to help you identify the reusable content and will not become part of your output.
5. If the **Replace selection with content reference** option is selected, the selection in the current topic will be replaced with a content reference (`@conref`) that points to the new reusable component. If multiple elements are selected (for example, multiple steps or list items), the selection is replaced with a content reference range (`@conref` and `@conrefend`).
6. Select a file name and location to save the topic containing the reusable component and click **Save**. It is considered best practice to save or store reusable components in an area set aside for that purpose.

A file is created that contains **one** reusable component. You can reference the reused content in other topics by using a content reference *(on page 3217)* or content key reference *(on page 3219)*. Also, if the **Replace selection with content reference** option was selected, Oxygen XML Editor replaces the selected content with a content reference that will be displayed in your current topic with a gray background and it can only be edited in the source file (the new reusable component). To edit the source file, click the  **Edit Content** icon at the beginning of the content reference.

Inserting a Reusable Content Component

Oxygen XML Editor includes an **Insert Reusable Content** action that allows you to easily insert a reusable content component that you created using the **Create Reusable Component** action *(on page 3236)*.

CAUTION:
This action is only designed to insert reusable components created using the Oxygen XML Editor **Create Reusable Component** action. It assumes certain things about the structure of the reusable content file that may not be true of reusable content created by other methods and it may not provide the expected results if used with content that does not have the same structure.

The **Insert Reusable Content** action creates a DITA `@conref` to insert the content, and creates a parent element for the `@conref` attribute based on the type of the reusable element in the reusable component file. This action ensures that the correct element is used to create the `@conref`. However, that element must still be inserted at a point in the current topic where that element type is permitted.

To insert a reusable component that was created using the **Create Reusable Component** action, follow these steps:

1. Place the cursor at the insertion point where you want the reusable component to be inserted.
2. Select the **Insert Reusable Component** action that is available in the **DITA** menu or the **Reuse** submenu of the contextual menu.
   The **Insert Reusable Component** dialog box is displayed.
3. Locate the reusable content file that you want to insert its content.
4. If you select **Content reference** in the **Insert as** drop-down list, the action will add a `@conref` attribute to the DITA element at the current location. If you select **Copy** in the drop-down list, the content of the reusable component file will simply be pasted at the current location (assuming the content is valid at the current location).
5. Click **Insert** to perform the action.

Working with Variable Text in DITA

You may often find that you want a certain piece of text in a topic to have a different value in various circumstances. For example, if you are reusing a topic about a feature that is shared between several products, you might want to make the name of the product a variable so that the correct product name is used in the manual for each product.

For example, you might have a sentence like this:

```
The quick-heat feature allows [product-name] to come up to temperature quickly.
```

You need a way to substitute the correct product name for each product.

One way to do this would be to use conditional profiling to provide conditional values using the `@product` profiling attribute, as in the following example:

```
<p>The quick-heat feature allows
    <ph product="basic">Basic Widget</ph>
    <ph product="pro">Pro Widget</ph>
to come up to temperature quickly.</p>
```

However, this approach means that you are repeating the product names over and over again everywhere the product name is mentioned. This is time consuming for authors and will create a maintenance problem if the product names change.

The alternative is to use a key reference, as in the following example:

```
<p>The quick-heat feature allows <ph keyref="product"/>
   to come up to temperature quickly.</p>
```

The definition of the key reference determines the name of the product:

```
<keydef keys="product" product="basic">
    <topicmeta>
      <keywords>
        <keyword>Basic Widget</keyword>
      </keywords>
    </topicmeta>
  </keydef>
  <keydef keys="product" product="pro">
    <topicmeta>
      <keywords>
        <keyword>Pro Widget</keyword>
      </keywords>
    </topicmeta>
  </keydef>
```

When the content is published, the value defined in the *product* key will be inserted for each product.

Inserting a Keyref

To insert a defined key reference *(on page 3107)* into a document in Oxygen XML Editor **Author** mode, use one of the following methods (the method you choose simply depends on which Oxygen XML Editor feature you prefer):

- **DITA Reusable Components View Method**

  Use the **DITA Reusable Components** view *(on page 3242)* to insert a *variable reference* to the defined key *(on page 3107)*. For example, in the **Keys** tab, find a key defined as a variable and double-click it. Oxygen XML Editor will insert the variable as a `<ph>` element with a `@keyref` attribute that references the specified key

- **Code Template Method**

  Add the source code pattern of the defined key *(on page 3107)* to a code template *(on page 226)* so that it appears in the list of proposals in the *Content Completion Assistant (on page 3418)*. For example, the code pattern could be something like `<ph keyref="product">` for defined *product* key.

- **Reuse Content Dialog Box Method**

  Use the  **Reuse Content** action on the main toolbar to open the **Reuse Content** dialog box *(on page 3224)*. Use the **Key** option to select a key that is defined as a variable (key reference to metadata) *(on page 3230)* and Oxygen XML Editor will insert the variable as a `<ph>` element with a `@keyref` attribute that references the specified key.

- **Manual Method**

  Manually insert the `@keyref` attribute using the attributes editor as follows:
  1. Press **Enter** and select a DITA element (for example, `<ph>`) that supports the `@keyref` attribute.
  2. Select  **Edit Attributes** from the contextual menu (or simply press **Alt+Enter**) to bring up the attributes editor *(on page 640)*.
  3. In the **Name** field, select **keyref**.
  4. In the **Value** field, select or enter the name of the defined key *(on page 3107)*.

Doctales - Key Reference (keyref)

Working with DITA 1.3 Key Scopes

DITA 1.3 includes the possibility of using a concept called *Key Scopes* (or scoped keys). It allows you to reuse a topic in multiple places within the same *DITA map (on page 3419)*, but with slightly different content in each instance.

Key Scopes Use-Case

Suppose that you develop a software product and you have a topic in your user guide that explains how to install your product on a Windows operating system. Suppose that the steps are exactly the same for installing it on Linux and the only difference is the name of the operating system. Therefore, it would be helpful if you could reuse the exact same content in two different topics, but with the name of the operating

system different in each instance. In DITA 1.2, this is not possible since keys can only be resolved to a single value. However, with the DITA 1.3 *Key Scopes* mechanism, you can define multiple values for the same key depending on the context.

How to Use Key Scopes in Oxygen XML Editor

To use DITA 1.3 key scopes in Oxygen XML Editor, follow these steps:

1. Define the keys *(on page 3207)* to be used in multiple places within your *DITA map*.
2. For each particular topic that contains the keys, define the key scopes:
    a. Right-click the topic in the **DITA Maps Manager** *(on page 3073)* and select **Edit properties**.
    b. In the **Keys** tab *(on page 3111)*, enter a value (or multiple values) in the **Key scopes** field.
    c. Click **OK** to save your changes.
3. Save the *DITA map*.

    Result: In the **DITA Maps Manager** *(on page 3073)*, you can now see the key scopes in brackets and when you open each topic reference.

    Figure 807. Key Scopes in DITA Maps Manager

    
    The content will also be expanded in **Author** mode according to the context of the key scope you defined for that particular topic. Also, when you transform the *DITA map*, the scoped keys will be reflected in the published content.

Oxygen XML Blog: DITA 1.3 Key Scopes - Next Generation of Reuse
Oxygen Video Tutorial: DITA 1.3 (Key Scopes, Branch Filtering)
Doctales - Key Scopes

Working with DITA 1.3 Branch Filtering

DITA 1.3 allows you to use a mechanism called *Branch Filtering* that enables you to set filtering conditions for specific branches of a *DITA map (on page 3419)*. This makes it possible for multiple conditional profiles to be applied within a single publication, each time with a different filter.

Branch Filtering Use-Case

Suppose that you sell two models of a mobile phone and you need to create a brochure for each model. You want both brochures to have the same structure and most of the content is the same for both brochures. The only differences are in the values for certain details (for example, the model name, size dimensions, battery life, etc.) Therefore, it would be helpful if you could use the same topic and reference it twice in the same map, with each reference using different filtering conditions. In DITA 1.2, this is not possible since you can only apply one DITAVAL filter to a map. However, with the DITA 1.3 *Branch Filtering* mechanism, you can reuse content multiple times within the same map, each time using different filters.

How to Use Branch Filtering in Oxygen XML Editor

To use DITA 1.3 branch filtering in Oxygen XML Editor, follow these steps:

1. The support for DITA 1.3 must be enabled in the DITA preferences page *(on page 278)*.
2. Assuming you have already defined your profiling attributes *(on page 681)*, create a DITAVAL filter file *(on page 3343)*.
3. Insert a reference to the DITAVAL filter file in the *DITA map*:
    a. Right-click the *DITA map* reference in the **DITA Maps Manager** *(on page 3073)* and select **Append Child > DITAVAL Reference**.
    b. Select the DITAVAL file.
    c. Click **Insert and Close**.
4. Save the *DITA map*.

    Result: You can now see the **ditaval** files referenced in the **DITA Maps Manager** *(on page 3073)* and when you transform the *DITA map*, filtered content will be reflected in the published output.

Figure 808. Branch Filtering in DITA Maps Manager

Working with DITA 1.3 Key Scopes *(on page 3239)*

Oxygen XML Blog: DITA 1.3 Branch Filtering - Next Generation of Reuse

Oxygen Video Tutorial: DITA 1.3 (Key Scopes, Branch Filtering)

DITA Reusable Components View

The **DITA Reusable Components** view is helpful if you use a large number of keys or reusable components in your DITA project. It collects all of the keys and reusable components that are defined in the *root map (on page 3424)* and presents them in a side view where you can easily locate and insert references to them. It recollects the keys anytime the *root map* is changed *(on page 3090)* or you switch the editor focus to a different file.

If the view is not displayed, it can be opened by selecting it from **Window > Show View**. By default, it appears in the bottom-right section of the editor.

Tip:
You can also assign a keyboard shortcut to open the view using the **Menu Shortcut Keys** preference page *(on page 303)*.

It includes the following tabs:

- **Keys** *(on page 3243)* - Displays all the *keys* that are defined in the *root map (on page 3424)* and provides ways to easily insert references to them as cross reference links, key references, or variables. It includes a search field, some filtering and sorting options to help you find particular keys, and some contextual menu actions. It also supports drag and drop actions and double-clicking a key is the fastest way to insert a reference.

  Note:
  If the keys are gathered from peer DITA maps (used in cross publication references), the keys that define variables are not presented.

- **Components** *(on page 3247)* - Displays all the *reusable components* found in the *root map (on page 3424)* and provides ways to easily insert them as content references or content key references. To determine which components to display in this tab, Oxygen XML Editor looks for any *topicref* in the *root map (on page 3424)* that is marked as *resource-only* and then looks for elements with an assigned `@id` attribute value. This tab includes a search field, some filtering options, and some simple links and contextual menu actions to quickly insert references or open their source file. It also supports drag and drop and double-clicking actions.
- **Media** *(on page 3249)* - Displays all images referenced as keys in the root map along with all images found in the user-defined working sets.

Keys Tab

The **DITA Reusable Components** view collects all the *keys* that are defined in the current *root map (on page 3424)* and displays them in the **Keys** tab. This tab has two view modes. The default *tiles* style view mode and a *table* style view mode.

Tiles Mode

The default *tiles* mode displays the keys as blocks (cards). The advantage of this display mode is that more information about each particular key can be seen even when the view is sized with a small width. Each block (card) displays the name of the key (the value of the `@keys` attribute), followed by its description and/or `@href` value, then followed by the name of the DITA map file where the key is defined.

Figure 809. DITA Reusable Components View - Keys Tab (Default tiles mode)

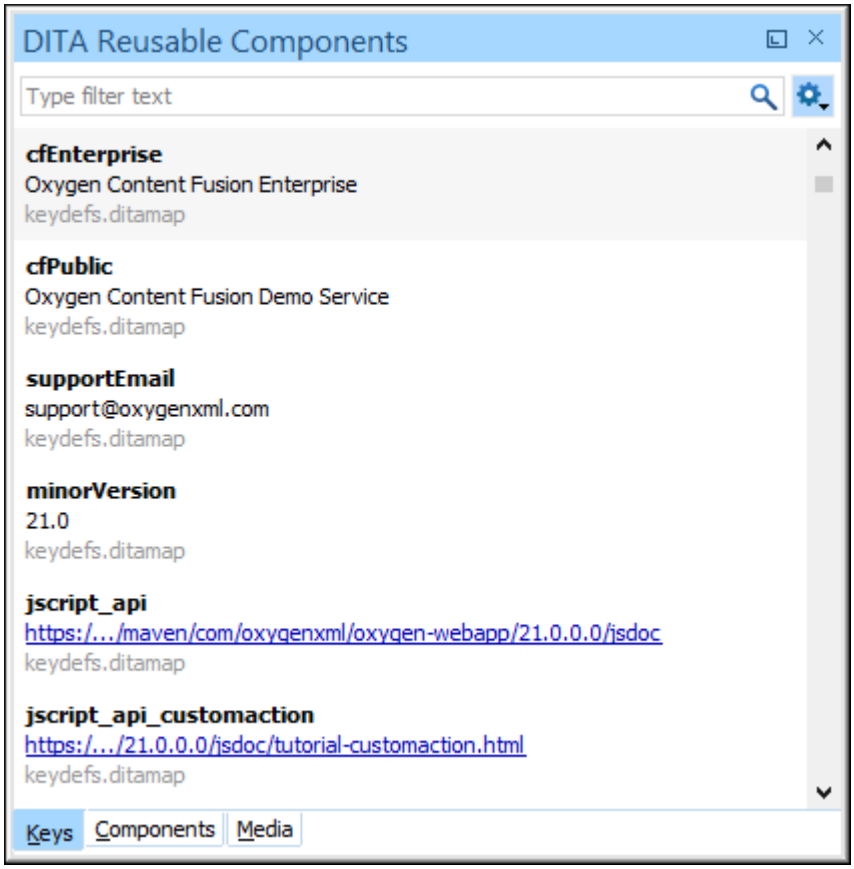

Table Mode

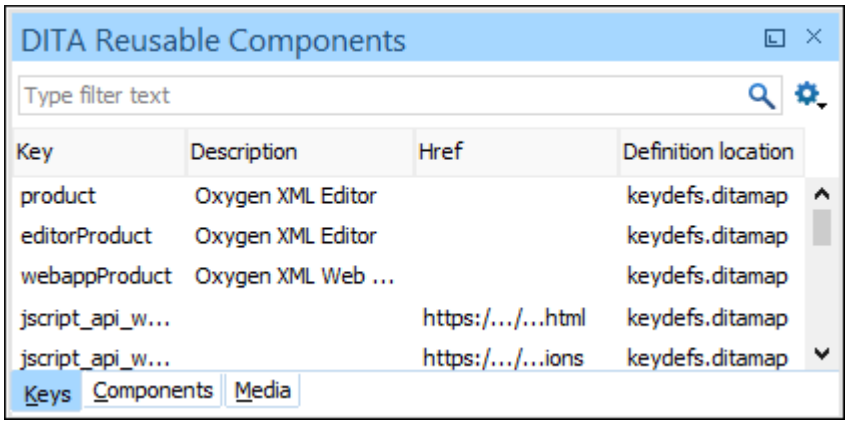
You can switch to a *table* style display mode by selecting the **Table mode** toggle action from the **Settings** menu. The advantage of this display mode is that more keys can be listed at once. In this mode, keys that are defined with a text value in the `<navtitle>` or `<keyword>` element have that value listed in the **Description** column, while keys that are defined with a value in an `@href` attribute have that href value listed in the **Href** column.

Figure 810. DITA Reusable Components View - Keys Tab (Table mode)



Both display modes in the **Keys** tab include a variety of features and options:

Search Filter

You can enter text in the filter field at the top of this tab to filter the list and search for specific keys.

Sorting

Tiles Mode: In the default *tiles* display mode, to sort the keys alphabetically in ascending order, select **Sort by key name** from the **Settings** menu.

Table Mode: In the *table* display mode, the following columns can be sorted by clicking the heading:

- **Key** - The name of the key (the value of the `@keys` attribute).
- **Description** - The description of the key that is obtained from its definition. Keys that are defined with a text value in the `<navtitle>` or `<keyword>` element have that value listed in this column.
- **Href** - Keys that are defined with a value in an `@href` attribute have that href value listed in this column.
- **Definition Location** - The name of the *DITA map (on page 3419)* where the key is defined.

Double-Click Mechanism

You can double-click any key listed in this tab to insert a key reference at the current cursor position or surrounding the current selection.

- If the selected key points to an `@href` value, it is inserted as a cross reference link (*xref*) *(on page 3254)*.
- If the selected key is a reference to an image, it is inserted as an `<image>` element.
- If the selected key does not have an associated `@href`, it is inserted as a variable reference (*ph*) *(on page 3237)*.

Drag and Drop Mechanism

You can drag a key from this tab and drop it in the main editor to insert a key reference at the current cursor position.

- If the selected key points to an `@href` value, it is inserted as a cross reference link (*xref*) *(on page 3254)*.
- If the selected key is a reference to an image, it is inserted as an `<image>` element.
- If the selected key does not have an associated `@href`, it is inserted as a variable reference (*ph*) *(on page 3237)*.

Contextual Menu Actions

Insert as Link

Inserts a cross reference link (*xref*) *(on page 3254)* to the selected key at the current cursor position or surrounding the current selection.

Insert as Variable

Inserts a variable reference (*ph*) *(on page 3237)* to the selected key at the current cursor position or surrounding the current selection. However, if the selected key is a reference to an image, this action inserts the key reference in an `<image>` element.

Insert as Keyref

Presents a submenu with all the elements that can be inserted at the current cursor position. Selecting an element will insert that element at the current cursor position or surrounding the current selection with a `@keyref` attribute and its value set to the selected key.

Insert as Figure

Available if the selection is an image, it inserts the image inside a figure element (`<fig>`). Note that the `<title>` element of the inserted figure will be empty.

Rename Key

Opens a refactoring wizard *(on page 856)* where you can easily rename the key and define the scope of the operation. It also updates all references to it.

Notes:

- This action does not work on DITA 1.3 key scopes.
- This action is only available if the DITA map opened in the **DITA Maps Manager** is also selected as the **Root map**.

Go to Definition

Opens the DITA map where the key is defined.

Search References

Searches for all references to the selected key in the entire DITA map structure.

Group by Definition Location (Available in Table mode only)

A toggle action that can be used to group (and sort) all the keys based on the value in the **Definition Location** column.

Settings Menu

This menu includes the following options:

Filtering Options

- **Show all** - Shows all defined keys found in the current *root map (on page 3424)*.
- **Show only variables** - Filters the keys to show only those defined as variable references *(on page 3237)*.
- **Show only maps and topics** - Filters the keys to show only those that reference DITA maps or topics.
- **Show only multimedia resources** - Filters the keys to show only those that reference multimedia resources (such as images).
- **Show only external resources** - Filters the keys to show only those that reference external resources (such as web links).
- **Show only keys with closest relative key scope** - Filters the presented keys to hide the fully qualified key scope paths and show only the relative key references that have the closest relative key scope path in the current context. This toggle option can be combined with any of the other filtering options. It is deselected by default. This option always remains synchronized with this same option in the **Media** tab so changing it one of the tabs also changes it for the other.

Sort by key name (Available in Tiles mode only)

Sorts the keys alphabetically in ascending order.

Table mode

A toggle action that switches between the *table* and *tiles* display modes.

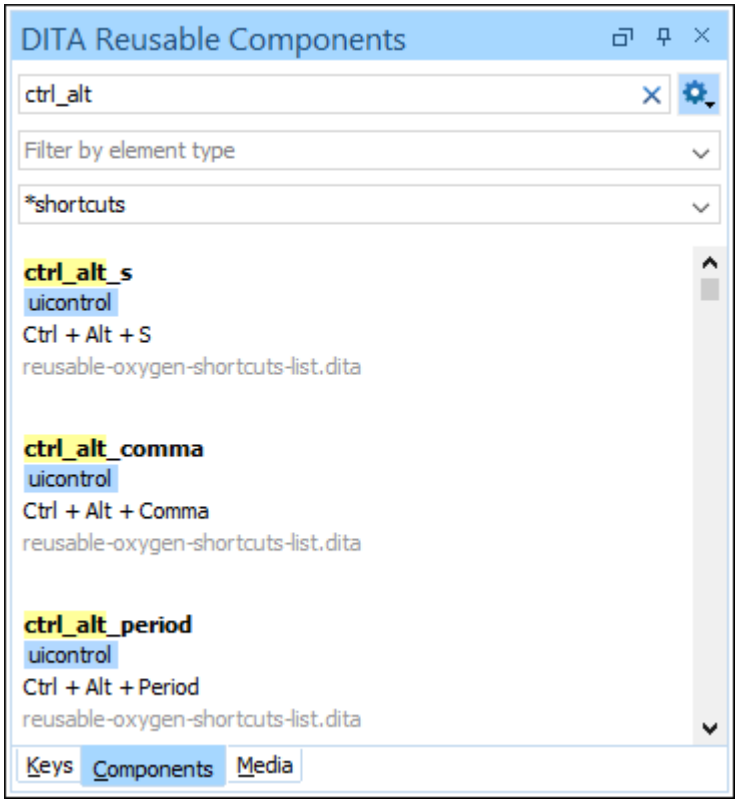
Components Tab

The **DITA Reusable Components** view collects all the topics from the current *root map (on page 3424)* that are marked as *resource-only*, then collects the reusable components from those topics, and displays them in the **Components** tab. To set a topic as *resource-only*, the `<topicref>` in the DITA map file must have a `@processing-role` attribute set like this:

```
<topicref href="topics/randomize-xml-content.dita" processing-role="resource-only"/>
```

The **DITA Reusable Components** view considers topic references that contain `processing-role="resource-only"` to be candidates to contain reusable components. The reusable components inside these topics are collected from all elements that have an *ID* specified. These reusable components are displayed in the **Components** tab along with the file name and the specific names of the elements that contain an *ID* attribute.

Figure 811. DITA Reusable Components View - Components Tab



The **Components** tab includes the following features and options:

Search Filter

You can enter text in the filter field at the top of this tab to filter the list and search for specific content inside the list of reusable components. This field supports many of the Lucene-based search patterns, such as wildcards (`*` or `?`), boolean operators (`AND`, `OR`, `NOT`), fuzzy searches (`~`), boosting searches (`^`), and more.

Settings Menu

This menu includes the following options:

Compact Mode

You can use this toggle action to switch the display for the **Components** tab to a compact visualization mode. When switched to **Compact mode**, fewer details are shown for each component, but more components are displayed in the view.

Reindex

You can use this action force a re-indexing of the reusable components.

Show Elements of Type

You can use this drop-down list to select specific types of elements to be displayed in the list of components. This can help you narrow down the list of possible source elements that you can select.

Source File(s)

You can use this combo box to search for specific source files (the topics that contain reusable components) or select a file from its drop-down list. You can also use wildcards (such as `*` or `?`) in this field.

Double-Click Mechanism

You can double-click any reusable component listed in preview window in this tab to insert it as a content reference or content key reference at the current cursor position or replace the current selection.

- If the parent topic of the selected component has a key defined, it is inserted as a content key reference (*conkeyref*) *(on page 3219)*.
- If the parent topic of the selected component does not have a key defined, it is inserted as a content reference (*conref*) *(on page 3217)*.

Drag and Drop Mechanism

You can drag a reusable component from the preview window in this tab and drop it in the main editor to insert a content reference or content key reference at the current cursor position.

- If the parent topic of the selected component has a key defined, it is inserted as a content key reference (*conkeyref*) *(on page 3219)*.
- If the parent topic of the selected component does not have a key defined, it is inserted as a content reference (*conref*) *(on page 3217)*.

Hover and Click Actions

If you hover over a component shown in the preview window, you have access to the following link actions:

Insert

Inserts the component as a content reference or content key reference at the current cursor position or replaces the current selection. If the parent topic has a key defined, it is inserted as a content key reference (*conkeyref*) *(on page 3219)*. Otherwise, it is inserted as a content reference (*conref*) *(on page 3217)*.

Open

Opens the source file that contains the reusable component.

Contextual Menu Actions

Insert Content Reference

Inserts the component as a content reference (*conref*) *(on page 3217)* at the current cursor position or replaces the current selection.

Insert Content Key Reference

Inserts the component as a content key reference (*conkeyref*) *(on page 3219)* at the current cursor position or replaces the current selection. This action is only available if the parent topic has a key defined.

Go to Definition

Opens the source file that contains the reusable component.

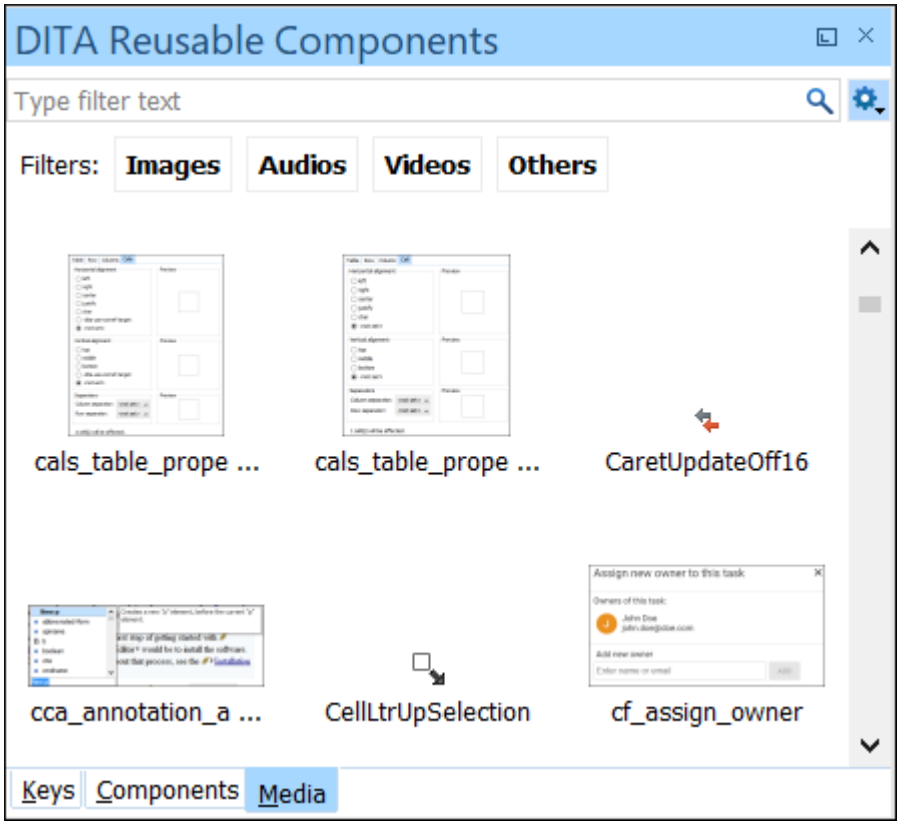
Search References

Searches for all references to the selected component in the entire *DITA map (on page 3419)* structure.

Media Tab

The **Media** tab displays all media resources (images, audio, video) referenced as keys in the current root map along with all audio, image, and video resources found in user-defined working sets *(on page 3251)*.

Figure 812. DITA Reusable Components View - Media Tab



The **Media** tab includes the following features and options:

Search Filter

You can enter text in the filter field at the top of this tab to filter the list and search for specific media resource key or file names in the list of available resources.

Resource Type Filter

You can quickly show resources of a specific type by clicking one of the type buttons (**Images, Audio, Video, Others**).

Settings Menu

This menu includes the following options:

Sort by date

Sorts the presented resources based on both the date when they were last modified and the date they were created.

Show only keys with closest relative key scope

Filters the presented keys to hide the fully qualified key scope paths and show only the relative key references that have the closest relative key scope path in the current context. This toggle option can be combined with any of the other filtering options. It is deselected by default. This option always remains synchronized with

this same option in the **Keys** tab so changing it one of the tabs also changes it for the other.

Configure working sets

Use this option to define folders where the media resources will be gathered. The **Media** tab will include audio, image, and video resources collected from the current root map as well as media resources located in the folders defined as active working sets. The working sets are defined at project level so that they can be easily shared with others. To save working sets in the global user-specific settings instead, in the **Preferences > Project Level Settings** page you can uncheck the **Save DITA media working sets at project level** checkbox.

Reload

Refreshes the list of displayed media resources. This is useful if resources were recently added in the searched folders.

Double-Click Mechanism

You can double-click any media resource in the list to add a reference to it.

Drag and Drop Mechanism

You can drag a media resource from the list and drop it in the main editor to add a reference to it.

Contextual Menu Actions

Insert As Image Reference

Inserts an image reference. If the resource is referenced using a key in the DITA map, an indirect reference using the defined key will be used. Otherwise, the reference will point directly to the resource location.

Insert As Audio Reference

Inserts an audio reference. If the resource is referenced using a key in the DITA map, an indirect reference using the defined key will be used. Otherwise, the reference will point directly to the resource location.

Insert As Video Reference

Inserts a video reference. If the resource is referenced using a key in the DITA map, an indirect reference using the defined key will be used. Otherwise, the reference will point directly to the resource location.

Insert As Embedded Reference

Inserts as an embedded reference. If the resource is referenced using a key in the DITA map, an indirect reference using the defined key will be used. Otherwise, the reference will point directly to the resource location.

Insert as Link

Inserts a link to the resource, either as a DITA `<xref>` or `<link>`, depending on the cursor position.

Insert as Variable

Inserts a variable reference (*ph*) *(on page 3237)* to the selected key at the current cursor position or surrounding the current selection. However, if the selected key is a reference to an image, this action inserts the key reference in an `<image>` element.

Insert as Keyref

Presents a submenu with all the elements that can be inserted at the current cursor position. Selecting an element will insert that element at the current cursor position or surrounding the current selection with a `@keyref` attribute and its value set to the selected key.

Insert as Figure

Available if the selection is an image, it inserts the image inside a figure element (`<fig>`). Note that the `<title>` element of the inserted figure will be empty.

Preview

Shows the selection in an **Image Preview** side view.

Open in System Application

Opens the default system editor/viewer associated with the resource type.

Show in Explorer/Finder

Opens the default file browser at the specific folder where the resource is located.

Items in the **Media** tab are presented in the following order:

- Key definitions are always presented first, in document order.
- Resources defined and collected from working sets are sorted alphabetically by name, for each folder separately.

Linking in DITA

DITA provides support for various types of linking between topics, some of which is automated, while others are specified by the author. Oxygen XML Editor provides support for all forms of linking in DITA.

Linking Between Parent, Child, and Sibling Topics

A *DITA map (on page 3419)* creates a hierarchical relationship between topics. That relationship map expresses a narrative flow from one topic to another, or it may be used as a classification system to help the reader find topics based on their classification, without creating a narrative flow. Since there may be various types of relationships between topics in a hierarchy, you may want to create links between topics in a variety of ways. For instance, if your topics are supposed to be organized into a narrative flow, you may want to have links to the next and previous topics in that flow. If your topics are part of a hierarchical classification, you may want links from parent to child topics, and vice versa, but not to the next and previous topics.

Parent, child, and sibling links are created automatically by the DITA output transformations (and may differ between various output formats). The kinds of links that are created are determined by the DITA *collection-type* attribute *(on page 3113)*.

In-Line Linking in the Content of a Topic

DITA supports linking within the text of a topic using the `<xref>` element. The destination of the link can be expressed directly using the `@href` attribute or indirectly using the `@keyref` attribute. If you use the `@keyref` attribute, you link to a key rather than directly to a topic. That key is then assigned to a topic in a map that includes that topic. This means that you can change the destination that a key points to by editing the key definition in the map or by substituting another map in the build.

Linking Between Related Topics

In addition to the relationships between topics that expressed by their place in the hierarchy of a map, a topic may be related to other topics in various ways. For instance, a task topic may be related to a concept topic that gives the background of the task, or to a reference topic that provides data needed to complete the task. Task topics may also be related to other tasks in a related area, or concepts to related concepts.

Typically, they are grouped in a list at the end of the topic, although this depends on the behavior of the output transformation. DITA provides two mechanisms for expressing relationships between topics at the topic level: the **Related Links** section of a topic and relationship tables in maps. To add related links, select **Related Link to Topic**, **Related Link to File**, or **Related Link to Web Page** from the **Link** drop-down menu from the toolbar (or the **Link** submenu in the contextual menu or **DITA** menu).

Tip:
You can use the **Find Similar Topics** action (available in the contextual menu or **DITA** menu) to quickly find related topics that can be added as related links. It opens the **Open/Find Resource** view and performs a search using text content from the `<title>`, `<shortdesc>`, `<keyword>`, and `<indexterm>` elements.

Managing Links

Links can break for a variety of reasons. The topic that a link points to may be renamed or removed. A topic may be used in a map that does not include a linked topic. A topic or a key may not exist in a map when a particular profile is applied. The **DITA Maps Manager** *(on page 3073)* provides a way to validate all the links in the documents that are included in the map *(on page 3118)*. This can include validating all the profiling conditions that are applied.

Related information

Short Video Clip: Learn DITA Editing with Oxygen - Various Ways to Insert Links

Hierarchical Linking in DITA Maps

To create hierarchical linking between the topics in a *DITA map (on page 3419)*, you set the appropriate value of the `@collection-type` attribute on the map. See the DITA documentation for the meaning of each of the values of the `@collection-type` attribute.

Note:
Publishing scripts determine when and how to create hierarchical links. The `@collection-type` attribute does not force a particular style of linking. Instead, it declares what the nature of the relationship is between the topics. The publishing scripts use that information to determine how to link topics. Scripts for different types of media might make the determination depending on what is appropriate for the particular type of media. You can provide additional instructions to the scripts using the `@linking` attribute.

To add the `@collection-type` to an item in a map:

1. Right-click the topic and choose **Edit Properties**. The **Edit Properties** dialog box is displayed.
2. In the **Attributes** tab, select the appropriate value from the **Collection type** drop-down list.
3. You can use the **Other attributes** table to add a value to the `@linking` attribute.

Linking in DITA Topics

Direct Links

Inline links can be created DITA topics using the `<xref>` element. The destination of the link can be expressed directly by using the `@href` attribute and the target can be another topic or a specific element within the other topic, another location within the same topic, a file, or a web link. You can also create direct *related links* to topics, files, or websites in a DITA topic using the `<related-links>` element.

Indirect Links Using Keys

The destination of the link can also be expressed indirectly by using keys *(on page 3207)* to create either inline links or *related links* (with the `@keyref` attribute). By using keys, you avoid creating a direct dependency between topics. This makes links easier to manage and can make it easier to reuse topics in various

publications. It can also be helpful in verifying the completeness of a publication, by ensuring that a publication map provides a key definition for every key reference used in the content.

Links based on keys require two pieces:

- Key Definition - Assigns a key to a topic so that other topics can link to it. For more information, see Defining Keys in DITA Maps *(on page 3107)*.
- Key Reference - Created in an `<xref>` element and specifies the key to link to.

The key reference points to a key definition, and the key definition points to a topic. Key definitions are created in maps, as an element on the `<topicref>` element that points to a topic. This allows you to assign a particular key to one topic in one map and to another topic in another map. When a topic that links to that key is used in each of these maps, the links work correctly in both maps.

Inserting a Link in Oxygen XML Editor

To insert a link in **Author** mode *(on page 363)*, use the actions available in the **Link** drop-down menu from the toolbar (or the **Link** submenu in the contextual menu or **DITA** menu). You can choose between the following types of inline links:

Cross Reference

Opens the **Cross Reference (xref)** dialog box *(on page 3257)* that allows you to insert a cross reference link to a target DITA resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. Once the target resource has been selected, you can also target specific elements within that resource. Depending on the context where it is invoked, the action inserts one of the following two elements:

- `<xref>` - Used to link to other topics or another location within the same topic and points to the target using the `@href` or `@keyref` attribute.
- `<fragref>` - A logical reference to a fragment element within a syntax diagram and points to the target using the `@href` or `@keyref` attribute.

File Reference

Opens a dialog box that allows you to insert a link to a target non-DITA file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. It inserts an `<xref>` element with either an `@href` attribute or a `@keyref` attribute. If you select **Location** for the target, the link is expressed in an `@href` attribute. If you select **Key** for the target, keys will be used to express the link in a `@keyref` attribute. You can select a key from the drop-down list or click the **Choose Key Reference** button to use the **Choose Key** dialog box *(on page 3258)*.

Web Link

Opens a dialog box that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. It inserts an `<xref>` element with either an `@href` attribute or a `@keyref` attribute. If you select **URL** for the target resource, the link is expressed in an `@href` attribute. If you select **Key** for the target, keys will be used to express the link in a `@keyref` attribute. You can select a key from the drop-down list or click the  **Choose Key Reference** button to use the **Choose Key** dialog box *(on page 3258)*.

Related Link to Topic

Opens the **Cross Reference (xref)** dialog box *(on page 3257)* that allows you to insert a link to a target DITA resource in a related links section that is typically at the bottom of your topic (although this depends on the behavior of the output transformation). The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. Specifically, it inserts a `<link>` element inside a *related-links* element.

Tip:
You can use the **Find Similar Topics** action (available in the contextual menu or **DITA** menu) to quickly find related topics that can be added as related links. It opens the **Open/Find Resource** view and performs a search using text content from the `<title>`, `<shortdesc>`, `<keyword>`, and `<indexterm>` elements.

Related Link to File

Opens a dialog box that allows you to insert a link to a target non-DITA file resource in a related links section that is typically at the bottom of your topic (although this depends on the behavior of the output transformation). The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. Specifically, it inserts a `<link>` element inside a *related-links* element. If you select **Location** for the target, the link is expressed in an `@href` attribute. If you select **Key** for the target, keys will be used to express the link in a `@keyref` attribute. You can select a key from the drop-down list or click the  **Choose Key Reference** button to use the **Choose Key** dialog box *(on page 3258)*.

Related Link to Web Page

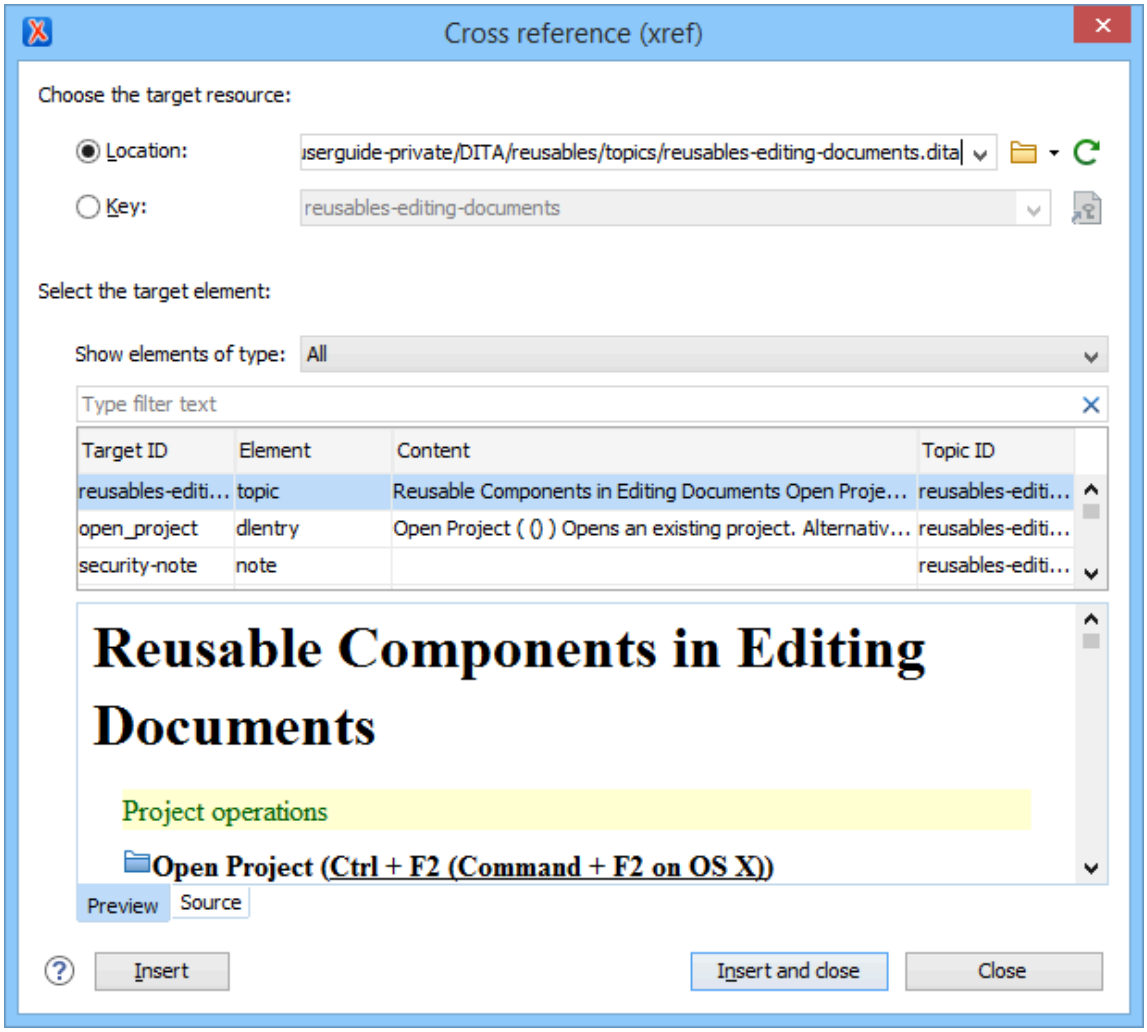
Opens the **Web Link** dialog box that allows you to insert a link to a target web-related resource in a related links section that is typically at the bottom of your topic (although this depends on the behavior of the output transformation). The target resource can be a URL or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. Specifically, it inserts a `<link>` element inside a *related-links* element. If you select **URL** for the target resource, the link is expressed in an `@href` attribute. If you select **Key** for the target, keys will be used to express the link in a `@keyref` attribute. You can select a key from the

drop-down list or click the **Choose Key Reference** button to use the **Choose Key** dialog box *(on page 3258)*.

Cross Reference (xref) Dialog Box

The **Cross Reference (xref)** dialog box is displayed when you insert a **Cross Reference** or **Related Link to Topic** (from the **Link** drop-down menu). It allows you to insert a link to a target resource at the current location within a document (for a **Cross Reference** link) or in a related links section (for a **Related Link to Topic**). The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource.

Figure 813. Cross Reference (xref) Dialog Box



This dialog box includes the following sections and fields:

Choose the Target Resource Section

Location

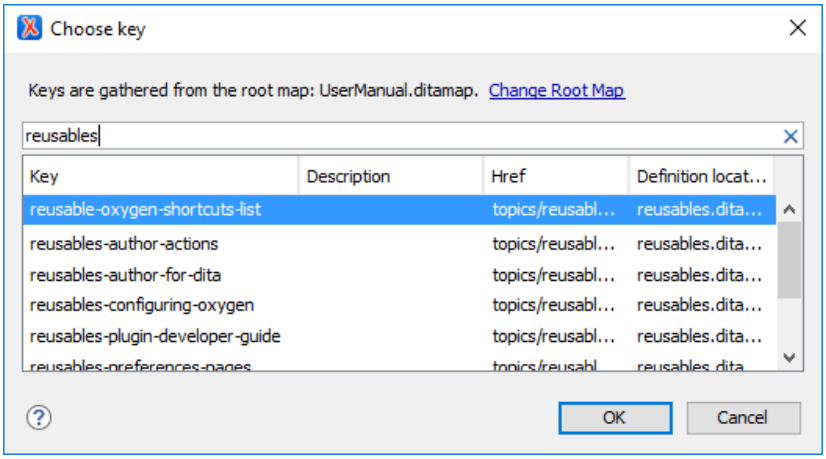
If you select **Location** for the target, the link is expressed in an `@href` attribute.

Key

If you select **Key** for the target, keys will be used to express the link in a `@keyref` attribute. You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that allows you to select one from a list of all the keys that are gathered from the *root map (on page 3424)* (you can also select one from the drop-down list in the **Key** field).

> **Tip:**
> You can also use the **DITA Reusable Components** view *(on page 3242)* for similar purposes.

Figure 814. Choose Key Dialog Box



The **Choose Key** dialog box includes the following:

- **Change Root Map** - Opens a small dialog box that allows you to select a *root map (on page 3090)*.
- **Search Filter** - You can enter text in the filter field at the top of the dialog box to filter the list and search for specific keys.
- **Sortable Columns** - The dialog box includes the following columns that can be sorted by clicking on the heading:
  - **Key** - The name of the key (the value of the `@keys` attribute).
  - **Description** - The description of the key that is obtained from its definition. Keys that are defined with a text value in the `<navtitle>` or `<keyword>` element have that value listed in this column.
  - **Href** - Keys that are defined with a value in an `@href` attribute have that href value listed in this column.
  - **Definition Location** - The name of the *DITA map (on page 3419)* where the key is defined.
- **Group by Definition Location** - A contextual menu action that can be used to group (and sort) all the keys based upon the value in the **Definition Location** column.

Select the Target Element Section

This section can be used to target a specific element inside the target resource.

Show elements of type

You can use this drop-down list to select specific types of elements to be displayed in the subsequent table. This can help you narrow down the list of possible source elements that you can select.

Text Filter Field

You can also use the text filter field to narrow down the list of possible source elements to be displayed in the subsequent table.

Element Table

Presents all the element IDs defined in the source topic. Use this table to select the **Target ID** of the element that you want to reference.

Preview Pane

Displays the content that will be references.

Source Pane

Displays the XML source code of the element to be referenced.

Once you click **Insert** or **Insert and close**, the configured cross reference is inserted into your document.

Tip:
You can easily insert multiple cross references by keeping the dialog box opened, using the **Insert** button.

Using Copy/Paste or Drag/Drop Actions to Insert a Cross Reference

Oxygen XML Editor also includes support for inserting cross reference links with simple copy/paste or drag/drop actions (additionally, you can insert them using the **Paste as Link** or **Paste as Link (keyref)** actions found in the **Paste Special** submenu from the contextual menu). The copied/dragged content must be an entire DITA XML element with an `@id` attribute or a `<topicref>`. Also, the location in the document where you paste or drop the link must be valid, although as long as the **Smart paste and drag and drop** option *(on page 189)* is selected in the **Schema-Aware** preferences page, if you try to paste it in an invalid location, Oxygen XML Editor will attempt to place it in a valid location, and may prompt you with one or more choices for where to place it.

When the link is inserted, Oxygen XML Editor automatically tries to populate certain attributes based on detected values. The `@format`, `@scope`, and `@type` attributes are populated if their corresponding options are selected in the **Inserting Links** section of the DITA Topics preferences page *(on page 283)*. Even if their corresponding options are not selected, the `@format` and `@scope` attributes are populated if their detected values are different than the default values.

Note:
For the sake of performance, the `@type` attribute is never automatically computed in the following cases:

- When using drag/drop or copy/paste actions from the **DITA Maps Manager** view *(on page 3073)* or from the **Keys** tab of the **DITA Reusable Components** view *(on page 3242)*.
- When using the **Paste as Link** or **Paste as Link (keyref)** actions to paste a topic reference that was copied from the **DITA Maps Manager** view *(on page 3073)* and its `<topicref>` elements do not have the `@type` attribute defined.

Typically, cross reference links are inserted with an `@href` attribute, but it is also possible to insert them with a `@keyref` attribute using the **Paste as Link (keyref)** contextual menu action or copy/paste or drag/drop actions. For the latter method, follow these steps :

1. In the **DITA Maps Manager** view *(on page 3073)*, make sure that the **Context** combo box *(on page 3077)* points to the correct map that stores the keys.
2. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager** *(on page 3073)*, select **Edit Properties**, and enter a value in the **Keys** field.
3. Copy an entire DITA element that has an ID attribute assigned to it from a topic with an assigned key, or a `<topicref>` from a *DITA map*.
4. Place the cursor at a location, where you want to insert the link.
5. Select the **Paste as Link (keyref)** action from the  **Paste Special** submenu from the contextual menu.

Linking with Relationship Tables in DITA

A relationship table is used to express relationships between topics outside of the topics themselves. The DITA publishing scripts can then create links between related topics when the content is published.

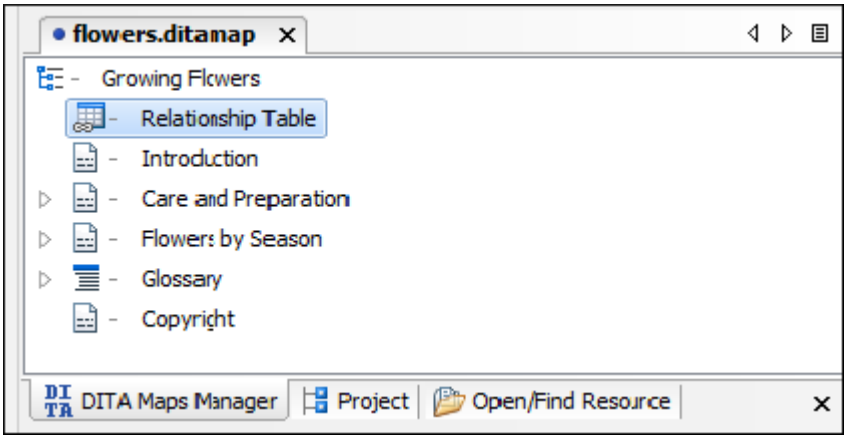
The reason for using a relationship table is to help make topics easier to reuse. If a topic links directly to another topic, this creates a dependency between the topics. If one topic is reused in a publication where the other is not used, the link is broken. By defining relationships between topics in a relationship table, you avoid creating this dependency.

To create an appropriate set of links between topics in multiple publications, you can create a separate relationship table for each publication. If you are creating multiple publications by applying profiling conditions to a single map, you can also profile your relationship table.

To create a relationship table, follow these steps:

1. If the map is currently open in the **DITA Maps Manager** *(on page 3073)*, double-click the map icon ( ) to open the map in **Author** mode. If it opens in **Text** mode, click **Author** at the bottom left to switch to **Author** mode.
2. Move the insertion point inside the *map* root element (usually `<map>`, but it might be `<bookmap>`, or another specialization of the `<map>` element). The easiest way to do this is to click below the title of the map in the editor and then press the up arrow once. Confirm that you are inside the *map* root element by checking the breadcrumbs at the top left of the editor window. You should only see the name of the *map* root element.
3. Select the **Insert Relationship Table** action on the toolbar or from the **Relationship Table** submenu of the contextual menu.
   The **Insert Relationship Table** dialog box is displayed.
4. Set the number of rows, the number of columns, a table title (optional), and select whether or not you want a table header. Click **Insert**.
5. Enter the type of the topics in the header of each column.
   The header of the table (the `<relheader>` element) already contains a `<relcolspec>` element for each table column. You should set the value of the `@type` attribute of each `<relcolspec>` element to a value such as *concept*, *task*, or *reference*. When you click in the header cell of a column (that is a `<relcolspec>` element), you can see all the attributes of that `<relcolspec>` element, including the `@type` attribute in the **Attributes** view *(on page 638)*. You can edit the attribute type in this view.
6. To insert a topic reference in a cell, place the cursor in a table cell and select **Insert Reference** *(on page 3138)* from the contextual menu or the **DITA Map** toolbar.
7. To add a new row to the table or remove an existing row use **Insert Relationship Row**/**Delete Relationship Row** from the contextual menu or the **DITA Map** toolbar.
8. To add a new column to the table or remove an existing column, use **Insert Relationship Column**/**Delete Relationship Column** contextual menu or the **DITA Map** toolbar. If you double-click the relationship table (or select it and press **Enter**, or choose **Open** from the contextual menu) the *DITA map* is opened in the editor with the cursor positioned inside the corresponding relationship table.
9. To add topic references to your relationship table, drag and drop topics from the **DITA Maps Manager** *(on page 3073)* or the **Project** *(on page 413)* view into the appropriate cell in the relationship table.
   See the DITA documentation for a full explanation of the relationship table format and its options. Note that you can change all the selections that you make here later by using the actions on the toolbar (or in the **Relationship Table** submenu of the contextual menu) or by editing the underlying XML in **Text** mode.
10. Save the *DITA map*.
    Relationship tables are also displayed in the **DITA Maps Manager** view *(on page 3073)*, along with the other elements in its *DITA map*.

Figure 815. Relationship Table



You can open the DITA map to edit the relationship table by doing one of the following:

- Double-click the appropriate relationship table in the **DITA Maps Manager** *(on page 3073)*.
- Select the relationship table in the **DITA Maps Manager** *(on page 3073)* and press **Enter**.
- Select **Open** from the contextual menu of the relationship table in the **DITA Maps Manager** *(on page 3073)*.

Content Completion in DITA

Oxygen XML Editor includes an intelligent *Content Completion Assistant (on page 3418)* that offers proposals for inserting structured language elements, attributes, and attribute values that are valid in the current editing context. The functionality of the feature is slightly difference for each editing mode:

- For detailed information about using the feature in **Text** mode, see: Content Completion Assistant in Text Mode *(on page 542)*.
- For detailed information about using the feature in **Author** mode, see: Content Completion Assistant in Author Mode *(on page 626)*.

In addition to the general functionality and types of proposals that are offered in the *Content Completion Assistant* (as described in the two topics listed above), some DITA-specific actions are offered as proposals in the content completion when using the feature in DITA documents. These actions include:

- **keyref** - Opens a pop-up window that allows you to choose a key from a list all the keys that are gathered from the context DITA map (except for those that point to *resource-only* topics). If the chosen key defines a keyword, the `@keyref` attribute is inserted inside a `<ph>` element, while if the chosen key points to a resource, the `@keyref` attribute is inserted inside an `<xref>` element.
- **conref** - Opens a pop-up window that allows you to choose reusable content from a list all the reusable components (elements with IDs in topics that are referenced as *resource-only* in the context DITA map). For each element, a preview of the content is shown in the documentation panel to the right of the pop-up. Once an element is chosen, a `@conref` or `@conkeyref` is inserted, depending on the defined component.

- **xref (cross reference)** - Opens the dialog box that allows you to insert a link to a specified target DITA resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. Once the target resource has been selected, you can also target specific elements within that resource. The action inserts an `<xref>` element with an `@href` or `@keyref` attribute that points to the target.
- **xref (web link)** - Opens a dialog box that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your DITA map structure. It inserts an `<xref>` element with either an `@href` attribute or a `@keyref` attribute.
- **simpletable** - Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table, and decide how the table is framed.

Publishing DITA Output

As a structured writing format, DITA produces structured content (content that is annotated with specific structural and semantic information rather than with formatting information). To create a publication, your *DITA map (on page 3419)* and its associated topics must be processed by a transformation script. That script is responsible for how the structural and semantic information in the DITA files is converted into formatting information for display.

Oxygen XML Editor publishes DITA content to various output sources using a bundled version of the DITA Open Toolkit. The DITA-OT is an open-source publishing engine that can publish DITA content to various output sources such as **XHTML**, **PDF**, or **Windows Help (CHM)**. Since it has a plugin-based architecture, it can be extended with extra plugins that either define new formats for conversion or customize an existing conversion format. You can run the DITA-OT from Oxygen XML Editor using a transformation scenario or you can run it directly from a command line: http://www.dita-ot.org/dev/topics/building-output.html.

The DITA-OT that comes bundled with Oxygen XML Editor contains more plugins than the standard DITA-OT that can be downloaded from their official website. For example, it contains pre-installed plugins for converting DITA content to Word, EPUB, WebHelp, or to publish to PDF using CSS to customize the output.

You can download and install extra publishing plugins either from the DITA Open Toolkit registry or from the list of free plugins *(on page 3354)* on the Oxygen XML Editor GitHub account.

Warning:
Keep in mind that there could be instances where there are differences between what you see in **Author** mode and what you see in the published output. This is typically due to certain limitations in the publishing engine, especially when the source documents contain advanced constructs such as

key scopes, branch filtering, chunking, or reusing content through direct references between topics marked for publishing.

DITA Map Transformation Scenarios

Built-in transformation scenarios allow you to transform *DITA maps (on page 3419)* to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, CHM, Kindle, and MS Word. Oxygen XML Editor also includes a special **Integrate/Install DITA-OT Plugins** *(on page 1496)* that can be used to integrate a DITA-OT plugin and a **DITA Map Metrics Report** transformation that generates a statistics report for your DITA map. All of them are listed in the **DITA Map** section in the **Configure Transformation Scenario(s)** dialog box *(on page 1600)*.

A variety of transformations scenarios are available for *DITA maps (on page 3419)*:

- Built-in transformation scenarios allow you to transform a *DITA map* to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, CHM, Kindle, Metrics Report, and MS Word.
- **Integrate/Install DITA-OT Plugins** *(on page 1496)* - Use this transformation scenario if you want to integrate a DITA-OT plugin *(on page 3351)*. This scenario runs an Ant task that integrates all the plugins from the DITA-OT/plugins directory.

DITA Map WebHelp Responsive Transformation

DITA content can be transformed into several types of WebHelp Responsive systems (with or without a feedback section). The WebHelp Responsive layout and features *(on page 1612)* are designed to adapt to any device and screen size to provide an optimal viewing and interaction experience. Oxygen XML Editor also provides numerous possibilities for customizing the WebHelp Responsive output *(on page 1697)*.

WebHelp Responsive Transformation Scenario

To publish a *DITA map (on page 3419)* as **WebHelp Responsive** output, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the **DITA Maps Manager** *(on page 3073)* toolbar.
2. Select the **DITA Map WebHelp Responsive** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

- Templates Tab *(on page 3291)* - This tab contains a set of built-in publishing templates *(on page 1658)* that you can use for the layout of your WebHelp system output. You can also create your own publishing templates or edit existing ones *(on page 1697)*.
- Parameters Tab *(on page 3297)* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the Parameters section *(on page 1474)* below for details about the most commonly used parameters for WebHelp Responsive transformations.
- Feedback Tab *(on page 3298)* - This tab is for those who want to add the **Oxygen Feedback** comments component at the bottom of each WebHelp page so that you can interact with your readers.
- Filters Tab *(on page 3299)* - This tab allows you to filter certain content elements from the generated output.
- Advanced Tab *(on page 3300)* - This tab allows you to specify some advanced options for the transformation scenario.
- Output Tab *(on page 3303)* - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to process the transformation.

Result: When the **DITA Map WebHelp Responsive** transformation is complete, the output is automatically opened in your default browser.

General Parameters for Customizing WebHelp Responsive Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

editlink.remote.ditamap.url

Use this parameter in conjunction with `editlink.web.author.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the custom URL of the *main DITA map*. For example, a GitHub custom URL might look like this: `https://getFileContent/oxyengxml/userguide/master/UserGuide.ditamap`.

editlink.web.author.url

This parameter needs to be used in conjunction with `editlink.remote.ditamap.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server.

The value should be set as the URL of the Web Author installation. For example: `https://www.oxygenxml.com/oxygen-xml-web-author/`.

editlink.present.only.path.to.topic

When this parameter is set to "true", the DITA topic path is displayed to the right of each topic title in the WebHelp Responsive output. Also, when this parameter is used, the **editlink.ditamap.edit.url**, **editlink.remote.ditamap.url**, and **editlink.web.author.url** parameters are ignored.

fix.external.refs.com.oxygenxml (Only supported when the DITA-OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.csh.disable.topicID.fallback

Specifies whether or not topic ID *fallbacks* are enabled when computing the mapping of context sensitive help and `resourceid` information is not available. Possible values are **false** (default) and **true**.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches

zero or more characters) or `'?'` (matches one character). For more information about the patterns, see https://ant.apache.org/manual/dirtasks.html#patterns.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine for indexing Japanese content in the WebHelp pages. The encoding for the dictionary must be **UTF8**.

webhelp.search.enable.pagination

Specifies whether or not search results will be displayed on multiple pages. Allowed values are `yes` or `no`.

webhelp.search.index.elements.to.exclude

Specifies a list of HTML elements that will not be indexed by the search engine. The value of the `@class` attribute can be used to exclude specific HTML elements from indexing. For example, the **div.not-indexed** value will not index all `<div>` elements that have a `@class` attribute with the value of **not-indexed**. Use a comma separator to specify more than one element.

webhelp.search.page.numberOfItems

Specifies the number of search results items displayed on each page. This parameter is only used when the **webhelp.search.enable.pagination** parameter is enabled.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.search.stop.words.include

Specifies a list of words that will be ignored by the search engine. Use a comma separator to specify more than one word.

webhelp.show.changes.and.comments

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is `no`.

webhelp.sitemap.base.url

Base URL for all the `<loc>` elements in the generated `sitemap.xml` file. If this parameter is specified, the **loc** element will contain the value of this parameter plus the relative path to the page. If this parameter is not specified, the **loc** element will only contain the relative path of the page (the relative file path from the `@href` attribute of a `<topicref>` element from the *DITA map*, appended to this base URL value).

webhelp.sitemap.change.frequency

The value of the `<changefreq>` element in the generated `sitemap.xml` file. The `<changefreq>` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `<changefreq>` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `<priority>` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `<priority>` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `<priority>` element is not added in `sitemap.xml`.

Parameters Specific to Oxygen WebHelp Responsive

webhelp.fragment.feedback

You can integrate **Oxygen Feedback** with your WebHelp Responsive output to provide a comments area at the bottom of each page where readers can offer feedback. When you create an **Oxygen Feedback** site configuration, an HTML fragment is generated during the final step of the creation process and that fragment should be set as the value for this parameter.

webhelp.default.collection.type.sequence

Specifies if the **sequence** value will be used by default when the `@collection-type` attribute is not specified. This option is helpful if you want to have *Next* and *Previous* navigational buttons generated for all HTML pages. Allowed values are **no** (default) and **yes**.

webhelp.enable.search.autocomplete

Specifies if the *Autocomplete* feature is enabled in the WebHelp search text field. The default value is `yes`.

webhelp.enable.html.fragments.cleanup

Enables or disables the automatic conversion of HTML fragments to well-formed XML. If set to **true** (default), the transformation automatically converts non-well-formed HTML content to a well-formed XML equivalent. If set to **false**, the transformation will fail if at least one HTML fragment is not well-formed.

webhelp.enable.scroll.to.search.term

Specifies whether or not the page should scroll to the first search term when opening the search results page. Possible values are **no** (default) and **true**.

webhelp.fragment.after.body

This parameter can be used to display a given XHTML fragment after the body in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.body.main.page

This parameter can be used to display a given XHTML fragment after the body in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.body.topic.page

This parameter can be used to display a given XHTML fragment after the body in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.body.search.page

This parameter can be used to display a given XHTML fragment after the body in the search results page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.body.terms.page

This parameter can be used to display a given XHTML fragment after the body in the index terms page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.logo_and_title

This parameter can be used to display a given XHTML fragment after the logo and title in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.search.input

This parameter can be used to display a given XHTML fragment after the search field in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.main.page.search (deprecated)

This parameter is deprecated. Use `webhelp.fragment.after.search.input.main.page` instead.

webhelp.fragment.after.search.input.main.page

This parameter can be used to display a given XHTML fragment after the search field in all the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.search.input.topic.page

This parameter can be used to display a given XHTML fragment after the search field in all the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.search.input.search.page

This parameter can be used to display a given XHTML fragment after the search field in all the search results page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.search.input.terms.page

This parameter can be used to display a given XHTML fragment after the search field in all the index terms page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.toc_or_tiles

This parameter can be used to display a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.top_menu

This parameter can be used to display a given XHTML fragment after the top menu in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.body

This parameter can be used to display a given XHTML fragment before the page body in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.body.main.page

This parameter can be used to display a given XHTML fragment before the page body in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.body.topic.page

This parameter can be used to display a given XHTML fragment before the page body in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.body.search.page

This parameter can be used to display a given XHTML fragment before the page body in the search results page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.body.terms.page

This parameter can be used to display a given XHTML fragment before the page body in the index terms page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.logo_and_title

This parameter can be used to display a given XHTML fragment before the logo and title. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.search.input

This parameter can be used to display a given XHTML fragment before the search field in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.main.page.search (deprecated)

This parameter is deprecated. Use `webhelp.fragment.before.search.input.main.page` instead.

webhelp.fragment.before.search.input.main.page

This parameter can be used to display a given XHTML fragment before the search field in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.search.input.topic.page

This parameter can be used to display a given XHTML fragment before the search field in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.search.input.search.page

This parameter can be used to display a given XHTML fragment before the search field in the search results page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.search.input.terms.page

This parameter can be used to display a given XHTML fragment before the search field in the index terms page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.toc_or_tiles

This parameter can be used to display a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.top_menu

This parameter can be used to display a given XHTML fragment before the top menu in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.footer

This parameter can be used to display a given XHTML fragment as the page footer in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

Important:
This parameter should only be used if you are using a valid, purchased license of Oxygen XML Editor (do not use it with a trial license).

webhelp.fragment.head

This parameter can be used to display a given XHTML fragment in the header section in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.head.main.page

This parameter can be used to display a given XHTML fragment in the header section in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.head.topic.page

This parameter can be used to display a given XHTML fragment in the header section in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.head.search.page

This parameter can be used to display a given XHTML fragment in the header section in the search results page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.head.terms.page

This parameter can be used to display a given XHTML fragment in the header section in the index terms page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.welcome

This parameter can be used to display a given XHTML fragment as a welcome message (or title). The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.header

This parameter can be used to display a given XHTML fragment after the header section in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.header.main.page

This parameter can be used to display a given XHTML fragment after the header section in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.header.topic.page

This parameter can be used to display a given XHTML fragment after the header section in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.header.search.page

This parameter can be used to display a given XHTML fragment after the header section in the search results page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.header.terms.page

This parameter can be used to display a given XHTML fragment after the header section in the index terms page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.search.input

This parameter can be used to display a given XHTML fragment before the search field in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.search.input

This parameter can be used to display a given XHTML fragment after the search field in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.main.content.area

This parameter can be used to display a given XHTML fragment before the main content section in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.main.content.area.main.page

This parameter can be used to display a given XHTML fragment before the main content section in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.main.content.area.topic.page

This parameter can be used to display a given XHTML fragment before the main content section in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.main.content.area.search.page

This parameter can be used to display a given XHTML fragment before the main content section in the search results page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.main.content.area.terms.page

This parameter can be used to display a given XHTML fragment before the main content section in the index terms page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.main.content.area

This parameter can be used to display a given XHTML fragment after the main content section in all types of pages. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.main.content.area.main.page

This parameter can be used to display a given XHTML fragment after the main content section in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.main.content.area.topic.page

This parameter can be used to display a given XHTML fragment after the main content section in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.topic.toolbar

This parameter can be used to display a given XHTML fragment before the toolbar buttons above the topic content in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.topic.toolbar

This parameter can be used to display a given XHTML fragment after the toolbar buttons above the topic content in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.topic.breadcrumb

This parameter can be used to display a given XHTML fragment before the breadcrumb component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.topic.breadcrumb

This parameter can be used to display a given XHTML fragment after the breadcrumb component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.publication.toc

This parameter can be used to display a given XHTML fragment before the publication's table of contents component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.publication.toc

This parameter can be used to display a given XHTML fragment before the publication's table of contents component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.topic.content

This parameter can be used to display a given XHTML fragment before the topic's content in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.topic.content

This parameter can be used to display a given XHTML fragment after the topic's content in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.feedback

This parameter can be used to display a given XHTML fragment before the **Oxygen Feedback** commenting component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.feedback

This parameter can be used to display a given XHTML fragment after the **Oxygen Feedback** commenting component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.before.topic.toc

This parameter can be used to display a given XHTML fragment before the topic's table of contents component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.after.topic.toc

This parameter can be used to display a given XHTML fragment after the topic's table of contents component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

webhelp.fragment.custom.search.engine.results

This parameter can be used to replace the search results area with custom XHTML content. The value of the parameter is the path to an XHTML file that contains your custom content.

webhelp.fragment.custom.search.engine.script

This parameter can be used to replace WebHelp's built-in search engine with your own custom search engine. The value of the parameter is the path to an XHTML file that contains the scripts required for your custom search engine to run.

webhelp.labels.generation.mode

Controls whether or not labels are generated in the output. These labels are useful because users can easily search for topics with the same label by simply clicking on the label presented in the output. Possible values are:

- **keywords-label** - Generates labels for each defined `<keyword>` element that has the `@outputclass` attribute value set to **label**.
- **keywords** - Generates labels for each defined `<keyword>` element. If the topic contains `<keyword>` elements with the `@outputclass` attribute value set to **label**, then only these elements will have labels generated for them in the output.
- **disable** - Disables the generation of labels in the Webhelp Responsive output.

webhelp.merge.nested.topics.related.links

Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, *Related Tasks*, *Related References*, *Related Information*) are merged into a single group. The default value is `yes`.

webhelp.publication.toc.hide.chunked.topics

Specifies if the table of contents will contain links for *chunked* topics. The default value is `yes`.

webhelp.publication.toc.links

Specifies which links will be included in the table of contents. The possible values are:

- **chapter** (default) - The TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The TOC will only include links for the current topic and its direct children.
- **all** - The TOC will include all links.

webhelp.publication.toc.tooltip.position

By default, if a topic contains a `<shortdesc>` element, its content is displayed in a tooltip when the user hovers over its link in the table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left**
- **right** (default)
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

webhelp.search.default.operator

Makes it possible to change the default operator for the search engine. Possible values are `and`, `or` (default). If set to `and` while the search query is WORD1 WORD2, the search engine only returns results for topics that contain both WORD1 and WORD2. If set to `or` and the search query is WORD1 WORD2, the search engine returns results for topics that contain either WORD1 or WORD2.

webhelp.search.stop.words.exclude

Specifies a list of words that will be excluded from the default list of *stop words* that are filtered out before the search processing. Use comma separators to specify more than one word (for example: `if,for,is`).

webhelp.show.breadcrumb

Specifies if the breadcrumb component will be presented in the output. The default value is `yes`.

webhelp.show.child.links

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is `no`.

webhelp.show.indexterms.link

Specifies if an icon that links to the index terms page will be displayed in the output. The default value is `yes` (meaning the index terms icon is displayed). If set to `false`, the index terms icon is not displayed in the output and the index terms page is not generated.

webhelp.show.main.page.tiles

Specifies if the tiles component will be presented in the main page of the output. For a *tree* style layout, this parameter should be set to `no`.

webhelp.show.main.page.toc

Specifies if the table of contents will be presented in the main page of the output. The default value is `yes`.

webhelp.show.navigation.links

Specifies if navigation links will be presented in the output. The default value is `yes`.

webhelp.show.print.link

Specifies if a print link or icon will be presented within each topic in the output. The default value is `yes`.

webhelp.show.related.links

Specifies if the related links component will be presented in the WebHelp Responsive output. The default value is `yes`. The `webhelp.merge.nested.topics.related.links` parameter can be used in conjunction with this one to merge the related links from nested topics into the links in the parent topic.

webhelp.show.publication.toc

Specifies if a table of contents will be presented on the left side of each topic in the output. The default value is `yes`.

webhelp.show.topic.toc

Specifies if a topic table of contents will be presented on the right side of each topic in the output. This table of contents contains links to each `<section>` within the current topic that contains an `@id` attribute and the section corresponding to the current scroll position is highlighted. The default value is `yes`.

webhelp.show.top.menu

Specifies if a menu will be presented at the topic of the main page in the output. The default value is `yes`.

webhelp.skip.main.page.generation

If set to `true`, the default main page is not generated in the output. The default value is `false`.

webhelp.top.menu.activated.on.click

When this parameter is activated (set to `yes`), clicking an item in the top menu will expand the submenu (if available). You can then click on a submenu item to open the item (topic). You can click outside the menu or press **ESC** to hide the menu. When set to `no` (default), hovering over a menu item displays the menu content.

webhelp.top.menu.depth

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is `3`. A value of `0` means that the menu has unlimited depth.

webhelp.topic.collapsible.elements.initial.state

Specifies the initial state of collapsible elements (tables with titles, nested topics with titles, sections with titles, index term groups). The possible values are `collapsed` or `expanded` (default value).

Parameters for Adding a Link to PDF Documentation in WebHelp Responsive Output

The following transformation parameters can be used to generate a PDF link component in the WebHelp Responsive output (for example, it could link to the PDF equivalent of the documentation):

webhelp.pdf.link.url

Specifies the target URL for the PDF link component.

webhelp.pdf.link.text

Specifies the text for the PDF link component.

webhelp.pdf.link.icon.path

Specifies the path or URL of the image icon to be used for the PDF link component. If not specified, a default icon is used.

webhelp.show.pdf.link

Specifies whether or not the PDF link component is shown in the WebHelp Responsive output. Allowed values are: **yes** (default) and **no**.

webhelp.pdf.link.anchor.enabled

Specifies whether or not the current topic ID should be appended as the name destination at the end of the PDF link. Allowed values are: **yes** (default) and **no**.

Layout and Features *(on page 1612)*

DITA Map PDF - based on HTML5 & CSS Transformation

Oxygen XML Editor includes a built-in **DITA Map PDF - based on HTML5 & CSS** transformation scenario based on a *DITA-OT CSS-based PDF Publishing plugin* that converts DITA maps to PDF using a CSS-based processing engine and an HTML5 intermediate format. Oxygen XML Editor comes bundled with a built-in CSS-

based PDF processing engine called **Oxygen PDF Chemistry**. Oxygen XML Editor also supports some third-party processors.

For those who are familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with *xsl:fo* customizations. This transformation also includes some built-in publishing templates that you can use for the layout of your PDF output and you can create your own templates or edit existing ones.

The following CSS-based PDF processors can be used:

- **Oxygen PDF Chemistry** - A built-in processor that is bundled with Oxygen XML Editor. For more information, see the Oxygen PDF Chemistry User Guide. This is the supported processor.
- **Prince Print with CSS** (not included in the Oxygen XML Editor installation kit) - A third-party component that needs to be purchased from http://www.princexml.com.
- **Antenna House Formatter** (not included in the Oxygen XML Editor installation kit) - A third-party component that needs to be purchased from http://www.antennahouse.com/antenna1/formatter/.

How to Create the Transformation Scenario

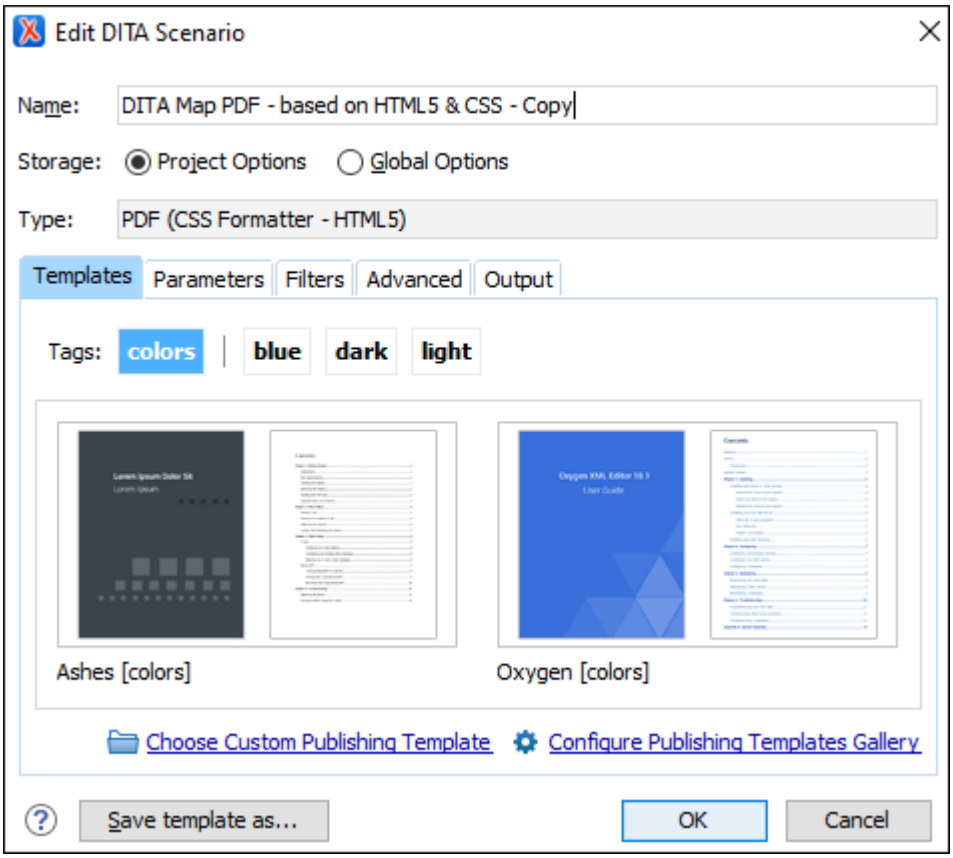
To create a **DITA Map PDF - based on HTML5 & CSS** transformation scenario, follow these steps:

1. Click the  **Configure Transformation Scenario(s)** button from the **DITA Maps Manager** *(on page 3073)* toolbar.
2. Select the **DITA Map PDF - based on HTML5 & CSS** transformation scenario.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

- **Templates** Tab *(on page 3291)* - This tab contains a set of built-in publishing templates that you can use for the layout of your WebHelp system output. You can also create your own publishing templates by saving one from the gallery and changing it.

Figure 816. DITA Map to PDF Templates



- **Parameters** Tab *(on page 3297)* - This tab includes numerous parameters that can be set to customize the transformation.
- **Filters** Tab *(on page 3299)* - This tab allows you to filter certain content elements from the generated output.
- **Advanced** Tab *(on page 3300)* - This tab allows you to specify some advanced options for the transformation scenario.
- **Output** Tab *(on page 3303)* - This tab allows you to configure options that are related to the location where the output is generated.

4. In the **Parameters** tab, configure any of the following parameters (if applicable):
   - **args.css** - Specifies a path to a custom CSS to be used in addition to those specified in the publishing template. The files must have URL syntax and be separated using semicolons. Also, the `dita.css.list` parameter must be left empty to use these files in addition to the selection in the **Styles** drop-down menu.
   - **css.processor.type**- This is where you choose the processor type. You can select between **Oxygen PDF Chemistry**, **Prince XML**, or **Antenna House**.
   - **css.processor.path.chemistry** (if you are using the **Oxygen PDF Chemistry** processor) - Specifies the path to the **Oxygen PDF Chemistry** executable file that will be run to generate the PDF. If

this parameter is not set, the transformation will use the processor specified in the **CSS-based Processors** preferences page *(on page 273)*.
- **css.processor.path.prince** (if you are using the **Prince Print with CSS** processor) - Specifies the path to the Prince executable file that will be run to produce the PDF. If you installed Prince using its default settings, you can leave this blank.
- **css.processor.path.antenna-house** (if you are using the **Antenna House Formatter** processor) - Specifies the path to the Antenna House executable file that will be run to produce the PDF. If you installed Antenna House using its default settings, you can leave this blank.
- **show.changes.and.comments** - When set to `yes`, user comments, replies to comments, and *tracked changes* are published in the PDF output. The default value is `no`.
- **figure.title.placement** - Controls the position of the figure title relative to the image. Allowed values are "top" and "bottom", "top" is the default

5. Click **OK** and run the transformation scenario.

Customizing the Output

For information about customizing the output, see CSS-based DITA to PDF Customization *(on page 1839)*.

Related Information:
Editing a Transformation Scenario *(on page 1597)*

Oxygen PDF Chemistry User Guide
CSS-based DITA to PDF Customization *(on page 1839)*

DITA Map PDF - based on XSL-FO Transformation

Oxygen XML Editor comes bundled with the DITA Open Toolkit that provides a mechanism for converting *DITA maps (on page 3419)* to PDF output.

Creating a DITA Map PDF - based on XSL-FO Transformation Scenario

To create a *DITA Map PDF - based on XSL-FO* transformation scenario, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the **DITA Maps Manager** *(on page 3073)* toolbar.
2. Select **DITA Map PDF - based on XSL-FO** and click the **Edit** button (or use the **Duplicate** button if your *framework (on page 3420)* is read-only).
3. Use the various tabs to configure the transformation scenario. In the **Parameters** tab, you can use a variety of parameters to customize the output. For example, the following parameters are just a few of the most commonly used ones:

- `show.changes.and.comments` - If set to `yes`, user comments, replies to comments, and *tracked changes* are published in the PDF output.
- `customization.dir` - Specifies the path to a customization directory.
- `editlink.present.only.path.to.topic` - When this parameter is set to "true", the DITA topic path is displayed to the right of each topic title in the PDF output.

4. Click **OK** and then the **Apply Associated** button to run the transformation scenario.

Related Information:
XSL FO-based DITA to PDF Customization *(on page 2104)*

DITA Map MS Office Word Transformation

Oxygen XML Editor comes bundled with a transformation scenario that allows you to convert *DITA maps (on page 3419)* to Microsoft Office Word documents. It utilizes the **DITA to Word plugin** created by Jarno Elovirta. This *plugin* contains a Word document named **Normal.docx** (located in: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/`*DITA-OT*`/plugins/com.elovirta.ooxml/resources`) that is used by the transformation scenario as a template to generate the final Word document.

Tip:
You can make general modifications to the **Normal.docx** template file to alter the published output. The Word application used to edit the **Normal.docx** should be configured with English locale as the style names for each Word element must be in English.

Configuring the Transformation Scenario

To configure a **DITA Map to MS Office Word** transformation scenario, follow these steps:

1. Open the DITA map in the **DITA Maps Manager** *(on page 3073)*.
2. Click the **Configure Transformation Scenario(s)** button from the **DITA Maps Manager** *(on page 3073)* toolbar.
3. Select **DITA Map MS Office Word**.
4. For advanced customizations, in the **Parameters** tab you can use any of the following parameters that are unique to this transformation scenario to specify paths to files that affect the output in various ways:
   - **dotx.file** - Specifies the path to a Word template file (`.docx`) that will be used in the transformation to generate the final Word document. Set this parameter if you want to use a different template file other than the **Normal.docx** file that is used by default.
   - **document.flat.xsl** - Specifies the path to a pre-process clean-up stylesheet.
   - **core.xsl** - Specifies the path to a core metadata stylesheet.
   - **custom.xsl** - Specifies the path to a custom metadata stylesheet.
   - **document.xsl** - Specifies the path to a main document stylesheet.
   - **comments.xsl** - Specifies the path to a comments stylesheet.
   - **numbering.xsl** - Specifies the path to a list and title numbering stylesheet.

- **footnotes.xsl** - Specifies the path to a footnote stylesheet.
- **document.xml.xsl** - Specifies the path to a document relations metadata stylesheet.
- **inkscape.exec** - Specifies the path to an Inkscape (open-source vector graphics editor) executable file.

5. Click **OK** and run the transformation scenario.

Result: The result of the transformation will automatically be opened in your system's default word processing application (such as Microsoft Word).

Migrating MS Office Documents to DITA *(on page 3375)*

DITA Map CHM (Compiled HTML Help) Transformation

To perform a *Compiled HTML Help (CHM)* transformation, Oxygen XML Editor needs `Microsoft HTML Help Workshop` to be installed on your computer. Oxygen XML Editor automatically detects if `HTML Help Workshop` is installed and uses it.

Note:
`HTML Help Workshop` might fail if the files used for transformation contain accents in their names, due to different encodings used when writing the *.hhp* and *.hhc* files. If the transformation fails to produce the CHM output but the *.hhp* (HTML Help Project) file is already generated, you can manually try to build the CHM output using `HTML Help Workshop`.

Changing the Output Encoding

Oxygen XML Editor uses the `htmlhelp.locale` parameter to correctly display specific characters of different languages in the output of the *Compiled HTML Help (CHM)* transformation. By default, the **DITA Map CHM** transformation scenario that comes bundled with Oxygen XML Editor has the `htmlhelp.locale` parameter set to `en-US`.

To customize this parameter, follow this procedure:

1. Use the **Configure Transformation Scenario(s)** (**Ctrl + Shift + C (Command + Shift + C on macOS)**) action from the toolbar or the **Document > Transformation** menu.
2. Select the **DITA Map CHM** transformation scenario and click the **Edit** button.
3. In the **Parameter** tab, search for the `htmlhelp.locale` parameter and change its value to the desired language tag.

> **Note:**
> The format of the `htmlhelp.locale` parameter is `LL-CC`, where `LL` represents the language code (`en`, for example) and `CC` represents the country code (`US`, for example). The language codes are contained in the `ISO 639-1` standard and the country codes are contained in the `ISO 3166-1` standard. For further details about language tags, go to http://www.rfc-editor.org/rfc/rfc5646.txt.

Customizing the CHM Output

There are several possibilities available for customizing the CHM output:

- You can use a custom CSS stylesheet to customize how the HTML content is rendered in the output:
  1. Create the custom CSS.
  2. Select the **DITA Map CHM** transformation scenario and click the **Edit** button.
  3. In the **Parameter** tab, set the `args.css` parameter to point to the location of your custom CSS and make sure the `args.copy.css` parameter is set to **yes** to instruct the transformation to copy the custom CSS to the output folder.
  4. Run the transformation.
- If you are familiar with XSLT, there are two XSLT stylesheets that are used in the transformation to compile various settings and components in the CHM output. They are found in the following directory: `OXYGEN_INSTALL_DIR/frameworks/dita/DITA-OT/plugins/org.dita.htmlhelp/xsl/map2htmlhelp`. The files are as follows:
  - **map2hhcImpl.xsl** - This file is used to compile the table of contents.
  - **map2hhpImpl.xsl** - This file contains information for compiling the CHM and various settings that are read by the *HTML Help Workshop* when creating the output.

DITA Map Kindle Transformation

To produce Kindle books from DITA XML content, follow these steps:

1. Start Oxygen XML Editor and open a *DITA map* in the **DITA Maps Manager** view *(on page 3073)*.
2. Click the **Configure Transformation Scenario(s)** button.
3. Select the **DITA Map EPUB** transformation and click the **Edit** button to edit it.
4. Run the transformation scenario and produce the EPUB.
5. Install the Amazon Kindle Previewer utility and use it to produce a Kindle book from the EPUB.

DITA Map Metrics Report Transformation

A **DITA Map Metrics Report** action is available on the **DITA Maps Manager** toolbar and in the **DITA Maps** main menu. It generates an overview report that contains useful statistics for a DITA map.

As an alternate approach, to create a metrics report from a *DITA map (on page 3419)* using a transformation scenario, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the **DITA Maps Manager** *(on page 3073)* toolbar.
2. Select the **DITA Map Metrics Report** scenario from the **DITA Map** section.
3. Run the transformation.

The generated HTML report contains information such as:

- The number of processed maps and topics.
- The number of `map/bookmap/topic/task/concept/reference` types in the DITA map.
- Content reuse percentage.
- Number of elements and attributes of different types used in the entire *DITA map* structure.
- Number of words and characters used in the entire *DITA map* structure.
- DITA conditional processing attributes used in the *DITA maps*.
- Processing instructions.
- External links.
- All `@outputclass` attribute values gathered from the DITA project.

Important:
If you have cross references that point to content outside the scope of the DITA map, that referenced content is not counted. For example, if you have links to topics that are not included in the DITA map hierarchy, the content in those topics is ignored when generating the statistics.

The metrics report can also be obtained in XML format, making it possible to construct a metrics report evolution between multiple versions of the same DITA project.

DITA Map Zendesk Publishing

Oxygen XML Editor includes a built-in transformation scenario that provides the ability to publish DITA topics to XHTML output and upload them directly as articles to the *Zendesk* Help Center.

Attention:
This feature is only available in the **Enterprise** edition of Oxygen XML Editor.

To run the transformation, follow these steps:

1. Start Oxygen XML Editor and open a *DITA map* in the **DITA Maps Manager** view *(on page 3073)*.
2. Click the **Configure Transformation Scenario(s)** button.
3. Create a new **DITA-OT** transformation scenario and choose the **Zendesk Help Center** transformation type.
4. Go to **Parameters** tab and set the following parameters:

   Host

The URL reference to the *Zendesk Help Center* (for example, `https://your-domain.zendesk.com`).

Username

The username (e-mail address) for the account used to upload the content.

API Token

An API token, generated in the *Zendesk* admin pages, necessary for authentication to the server: https://support.zendesk.com/hc/en-us/articles/226022787-Generating-a-new-API-token-.

Article category

The name of the category where the articles are uploaded. The category needs to be created in the *Zendesk* admin pages: https://support.zendesk.com/hc/en-us/articles/218222877-Organizing-knowledge-base-content-in-categories-and-sections#topic_hjs_tl4_kk.

Article section

The name of the section (inside the parent category) where articles are uploaded. The section needs to be created in the *Zendesk* admin pages: https://support.zendesk.com/hc/en-us/articles/218222877-Organizing-knowledge-base-content-in-categories-and-sections#topic_ysj_wtt_zz.

Note:
When publishing to a subsection, a path of section names separated by '///' can be passed (for example: `Main section///Subsection 1///Subsection 1.1`).

Create article draft

This setting controls whether the articles should be published (if the value is `false`) or saved as drafts (if the value is `true`). The default value is `false`.

Permission group name

The name of the Zendesk permission group that controls who edits and publishes articles: https://support.zendesk.com/hc/en-us/articles/203661966-Creating-managing-and-using-groups.

5. Save the changes and run the transformation.

Important:

There may be cases when the publishing breaks, presenting an error related to **HTTPS** certificates, similar to this one:

```
Error: org.zendesk.client.v2.ZendeskException: java.net.ConnectException: PKIX path
 building failed:
```

```
sun.security.provider.certpath.SunCertPathBuilderException: unable to find valid
 certification path
to requested target
```

This usually occurs if an HTTPS proxy server is installed in your company's network. In this case, if running on Windows, you can edit the transformation scenario you are using to publish **DITA** to **Zendesk** and in the **Advanced** tab, go to the **JVM Arguments** field and set this value:

```
-Djavax.net.ssl.trustStoreType=Windows-ROOT -Djavax.net.ssl.trustStore=C:\\Windows\\win.ini
```

Resources

For more information about publishing content to the Zendesk Help Center, watch the following video demonstration:

https://www.youtube.com/embed/QZ_9Fk_LOk8

Integrate/Install DITA-OT Plugins Transformation

Oxygen XML Editor comes bundled with a transformation scenario designed to integrate DITA-OT plugins *(on page 3422)*. These DITA-OT *plugins* are used for various customizations. It is called **Integrate/Install DITA-OT Plugins** and is found in the **DITA Map** section of the **Configure Transformation Scenario(s)** dialog box *(on page 1600)*.

Attention:
The integration will be performed on the DITA-OT version specified in the **DITA Open Toolkit** section of the **DITA** preferences page *(on page 277)*.

CAUTION:
Oxygen XML Editor support engineers do not officially offer support and troubleshooting assistance for custom DITA-OT distributions or custom installed DITA-OT plugins. If you discover any issues or inconsistent behavior while using a custom DITA-OT or a DITA-OT that contains custom DITA-OT plugins, you should revert to the default built-in DITA-OT.

Running the Transformation Scenario

To integrate a DITA-OT *plugin*, follow these steps:

1. If Oxygen XML Editor was installed in the default location, you may need to restart and run it as an administrator.
2. Select the **Apply Transformation Scenario(s)** or **Configure Transformation Scenario(s)** *(on page 1600)* action from the **DITA Maps Manager** toolbar (you could also use the same action on the main toolbar or open the **Transformation Scenarios** view *(on page 1607)*).

3. Select the **Integrate/Install DITA-OT Plugins** transformation scenario. If the *integrator* is not visible, select the **Show all scenarios** action that is available in the **Settings** drop-down menu.
4. Apply the scenario *(on page 1600)*.
5. Check the **Results** panel at the bottom of the application to make sure the build was successful.
6. Restart Oxygen XML Editor with your normal permissions.

Related Information:
Configure Transformation Scenario(s) Dialog Box *(on page 1600)*
Installing a DITA-OT Plugin *(on page 3351)*
Integrating a DITA Specialization *(on page 3363)*

DITA Topic Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios for transforming individual DITA Topics to HTML5, XHTML, or PDF output. They can be found in the **DITA** section in the **Configure Transformation Scenario(s)** dialog box *(on page 1600)*.

The available transformations scenarios for individual DITA topics include:

- **DITA HTML5** - This DITA-OT transformation scenario generates HTML5 output from a single DITA topic.
- **DITA XHTML** - This DITA-OT transformation scenario generates XHTML output from a single DITA topic. This was the first transformation scenario created for the DITA Open Toolkit and it originally served as the basis for all HTML-based transformations.
- **DITA PDF - based on HTML5 & CSS** - This transformation scenario converts individual DITA topics to PDF using a CSS-based processing engine and an HTML5 intermediate format. Oxygen XML Editor comes bundled with a built-in CSS-based PDF processing engine called **Oxygen PDF Chemistry**. Oxygen XML Editor also supports some third-party processors.

  For those who are familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with *xsl:fo* customizations. Another advantage of this transformation scenario is that you can use the same customization CSS *(on page 1868)* or publishing template *(on page 1856)* that you use for converting entire DITA maps.

  The transformation scenario automatically detects the currently selected context DITA map (root map) *(on page 3077)* so that keys and references are properly resolved (the detected context map is set as the value of the `args.root.map` parameter (this can be changed in the **Parameters** tab). It also automatically detects the currently applied profiling condition set *(on page 3328)* to be used as the default filtering option in the transformation scenario (this can be changed in the **Filters** tab).

  The transformation scenario also supports a parameter named `args.enable.root.map.key.processing` that can be used to specify whether or not the values for `@keyref` and `@conkeyref` attributes within the transformed topics are resolved. The possible values are:

- **no** - This means that the values for all `@keyref` and `@conkeyref` attributes are ignored in the transformation. This results in lower processing times.
- **yes** - This means that the values for any `@keyref` and `@conkeyref` attributes found in the transformed topic are processed and resolved using the value of the `args.root.map` parameter.
- **auto** - This means that the process will search for any `@keyref` and `@conkeyref` attributes within the transformed topic and if any are found, the values will be processed and resolved using the value of the `args.root.map` parameter. If none are found, the `@keyref` and `@conkeyref` attributes are ignored.

- **DITA PDF - based on XSL-FO** - This DITA-OT transformation scenario converts individual DITA topics to PDF using an *xsl:fo* processor.

Related Information:
Editing a Transformation Scenario *(on page 1597)*
Configure Transformation Scenario(s) Dialog Box *(on page 1600)*
Applying Associated Transformation Scenarios *(on page 1600)*
DITA Map Transformation Scenarios *(on page 3264)*

Running a DITA Transformation Scenario

To select and run a transformation scenario on your *DITA map*, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button on the **DITA Maps Manager** toolbar *(on page 3075)*. The **Configure Transformation Scenario(s)** dialog box *(on page 1600)* appears. This dialog box lists all the transformation scenarios that have been configured in your project. Oxygen XML Editor provides a default set of transformation scenarios, but the people in charge of your DITA system may have provided others that are specifically configured for your needs.
2. Select the transformation scenario you want to run and click **Apply Associated**. The transformation scenario runs in the background. You can continue to work in Oxygen XML Editor while the transformation is running. If there are errors or warnings, Oxygen XML Editor displays them when the transformation is complete. If the transformation is successful, Oxygen XML Editor opens the output in the appropriate application.
3. To rerun the same scenario again, click the **Apply Transformation Scenario(s)** button.

Creating or Editing a DITA-OT Transformation

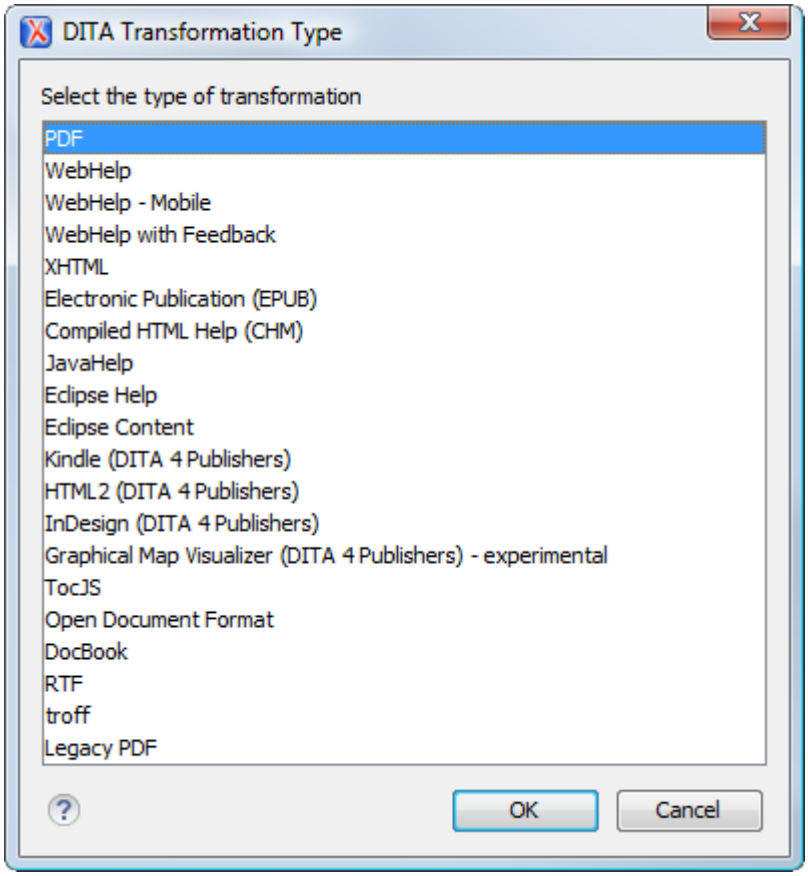
Creating a DITA-OT Transformation Scenario

To create a **DITA-OT Transformation** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s)** (**Ctrl + Shift + C (Command + Shift + C on macOS)**) action from the **DITA Maps Manager** toolbar, main toolbar, or the **Document > Transformation** menu. Then click the **New** button and select **DITA-OT Transformation**.
- Go to **Window > Show View** and select **Transformation Scenarios** to display this view. Click the **New Scenario** drop-down menu button and select **DITA-OT Transformation**.

Both methods open the **DITA Transformation Type** dialog box that presents the list of possible outputs.

Figure 817. DITA Transformation Type Dialog Box



Select the desired type of output and click **OK**. This opens the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- **Project Options** *(on page 3423)* - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options** *(on page 3420)* - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

Editing a DITA-OT Transformation Scenario

Editing a transformation scenario is useful if you need to configure some of its parameters.

To configure an existing transformation scenario, follow these steps:

1. Select the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on macOS))** action from the **DITA Maps Manager** toolbar, main toolbar, or the **Document > Transformation** menu.

   Step Result: The **Configure Transformation Scenario(s)** dialog box *(on page 1600)* is opened.

2. Select the particular transformation scenario and click the **Edit** button at the bottom of the dialog box or from the contextual menu.

   Note:
   Since transformation scenarios that are associated with built-in *frameworks (on page 3420)* are read-only, these scenarios will prompt you to use the **Duplicate** button and then edit the duplicated scenario *(on page 1599)*.

Result: This will open an **Edit scenario** configuration dialog box *(on page 1597)* that contains several tabs that allow you to configure the options that control the transformation.

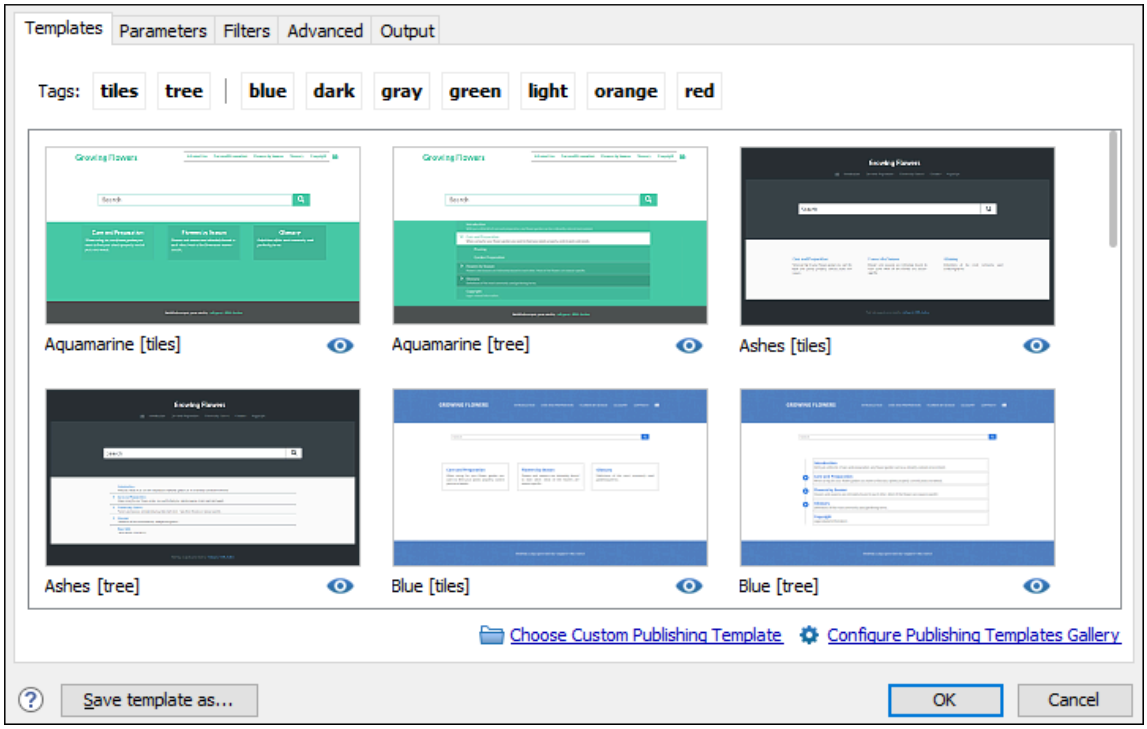
Related Information:
Creating a DITA-OT Plugin *(on page 3347)*
Installing a DITA-OT Plugin *(on page 3351)*
DITA Open Toolkit Documentation

Templates Tab (DITA-OT Transformations)

When you create a new transformation scenario *(on page 1504)* or edit an existing one *(on page 1597)*, a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Templates** tab is available for DITA-OT transformations with **WebHelp Responsive** or **PDF - based on HTML5 & CSS** output types and it provides a set of built-in publishing templates *(on page 1658)*. You can use one of them to publish your documentation or as a starting point for a new publishing template.

Figure 818. Templates Tab



Filtering and Previewing Templates

You can click on the tags at the top of the pane to filter the templates and narrow your search. Each built-in template also includes an **Online preview** icon in the bottom-right corner that opens a webpage in your default browser providing a sample of how the main page will look when that particular template is used to generate the output.

Built-in Templates Locations

Oxygen XML Editor scans the following locations to find the built-in templates to display in the dialog box:

- **WebHelp Responsive Templates** - All built-in WebHelp Responsive publishing templates are stored in the following directory: *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp.responsive/templates`.
- **PDF - based on HTML5 & CSS** - All built-in PDF publishing templates are stored in the following directories:
  - *DITA-OT-DIR*`/plugins/com.oxygenxml.pdf.css/templates`
  - *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp.responsive/templates`

Custom Templates Locations

Oxygen XML Editor scans the locations specified in the **DITA > Publishing** preferences page *(on page 284)* to find custom templates to display in the dialog box. You can access that preferences page directly from the **Template** tab by clicking on the **Configure Publishing Templates Gallery** link.

Selecting Custom Templates

Once you are finished configuring your template, you can click the **Choose Custom Publishing Template** link to select your template.

You can also add your custom templates *(on page 1701)* to the list of templates displayed in the **Templates** tab. To do this, store them in a directory, then click the **Configure Publishing Templates Gallery** link to open the **DITA > Publishing** preferences page *(on page 284)* where you can add that directory to the list. All the templates contained in your template directory will be displayed in the preview pane along with all the built-in templates.

Save Template As Button

You can use the **Save template as** button (at the bottom-left of the transformation dialog box) to export the currently selected template into a new template package that can be used as a starting point to create your own custom template *(on page 1864)*. Clicking this button will open a template package configuration dialog box *(on page 3294)* that contains some options and displays the parameters that will be exported to your template package.

Template Errors

When the **Templates** tab is opened, all templates (built-in and custom) are loaded and validated. Specifically, certain elements in the template descriptor file are checked for validity. If errors are encountered that prevents the template from loading, the following message will be displayed toward the bottom of the dialog box:

If you click the **More details** link, a window will open with more information about the encountered error. For example, it might offer a hint that the element is missing from the expected descriptor file structure.

Also, if a template could be loaded, but certain elements could not be found in the descriptor file, a warning icon (⚠) will be displayed on the template's image (in the **Templates** tab of the transformation dialog box). For example, this happens if a valid preview-image element cannot be found.

Sharing Publishing Template

To share a publishing template with others, following these steps:

1. Copy your template in a new folder.
2. Go to **Options > Preferences > DITA > Publishing** *(on page 284)* and add that new folder to the list.
3. Switch the option as the bottom of that preferences page to **Project Options**.
4. Share your project file (`.xpr`).

Resources

For more information about customizing publishing templates, watch our video demonstration:

https://www.youtube.com/embed/zNmXfKWXwO8

Related Information:

Publishing Templates *(on page 1658)*

Publishing Template Package Contents for PDF Customizations *(on page 1858)*

Publishing Template Package Contents for WebHelp Responsive Customizations *(on page 1661)*

Template Package Configuration Dialog Box

The **Save template as** button (at the bottom-left of the transformation dialog box for **WebHelp Responsive** or **PDF - based on HTML5 & CSS** transformations) can be used to export the currently selected template into a new template package that can be used as a starting point to create your own custom template *(on page 1864)*. The result will be a ZIP archive that contains a template descriptor file and other resources (such as CSS files) that were attached to the selected template.

Clicking the **Save template as** button opens a template package configuration dialog box contains the following options and components:

Name

Required field used to specify the name for the new template. This will become the text value of the `<name>` element in the template descriptor file. This information is displayed as the name of the template in the transformation scenario dialog box.

Description

Optional field used to specify a template description. This will become the text value of the `<description>` element in the template descriptor file. This information is displayed when the user hovers over the template in the transformation scenario dialog box.

Parameter Table

This table displays the parameters that will be exported. Only certain relevant parameters are exported. The parameters and their values will be inserted in the `<parameters>` section of the template descriptor file. If any of the parameter values point to a file path that references a template resource (such as CSS files, custom HTML fragments, images), those resources will automatically be copied to the new template package and their references will be changed accordingly.

Note:
Additional resources that are referenced in CSS files or other resources will not be copied to the new template package, so you will need to copy them manually and update their references in the template descriptor file.

Include WebHelp Customization

The same publishing template package can contain both a WebHelp Responsive and PDF customization and you can use the same template in both types of transformations (**DITA Map**

WebHelp Responsive *(on page 1473)* or **DITA Map to PDF - based on HTML5 & CSS** *(on page 1487)*). This option specifies that the custom template will include a WebHelp Responsive customization.

Include HTML Page Layout Files

For **WebHelp Responsive** customizations, select this option if you want to copy the default *HTML Page Layout Files (on page 1677)* into your template package. They are helpful if you want to change the structure of the generated HTML pages.

Include PDF Customization

The same publishing template package can contain both a WebHelp Responsive and PDF customization and you can use the same template in both types of transformations (**DITA Map WebHelp Responsive** *(on page 1473)* or **DITA Map to PDF - based on HTML5 & CSS** *(on page 1487)*). This option specifies that the custom template will include a PDF customization.

Save as

Use this field to specify the name and path of the ZIP file where the template will be saved.

Figure 819. Template Package Configuration Dialog Box

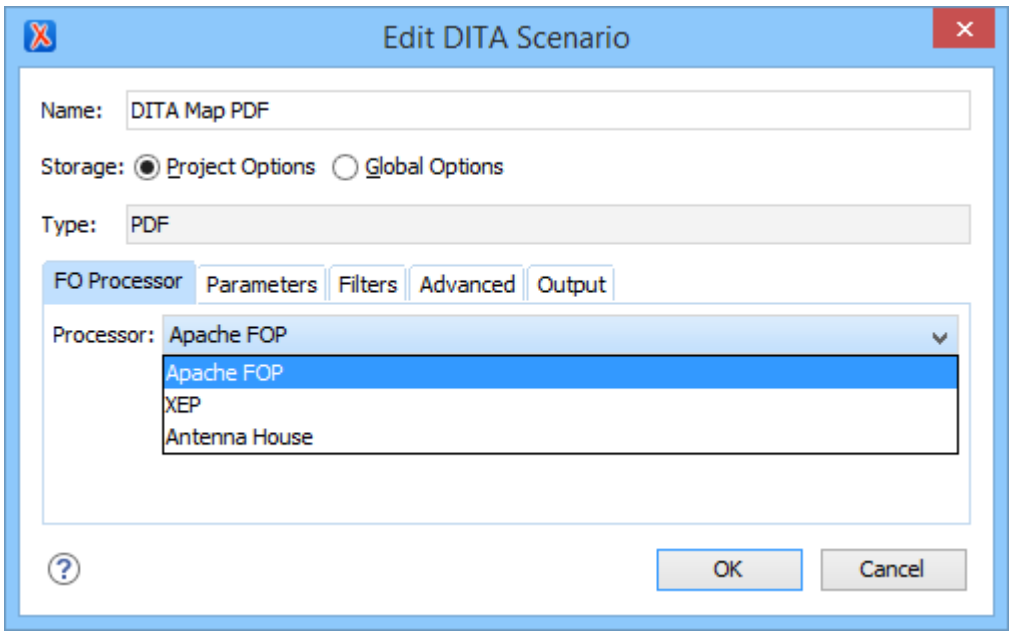
FO Processor Tab (DITA-OT Transformations)

When you create a new transformation scenario *(on page 1504)* or edit an existing one *(on page 1597)*, a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab is available for DITA-OT transformations with a **PDF** output type.

This tab allows you to select an FO Processor to be used for the transformation.

Figure 820. FO Processor Configuration Tab



You can choose one of the following processors:

Apache FOP

The default processor that comes bundled with Oxygen XML Editor.

XEP

The RenderX XEP processor. If XEP is already installed, Oxygen XML Editor displays the detected installation path under the drop-down menu. XEP is considered installed if it was detected in one of the following sources:

- XEP was configured as an external FO Processor in the **FO Processors** option page *(on page 269)*.
- The system property *com.oxygenxml.xep.location* was set to point to the XEP executable file for the platform (for example: `xep.bat` on Windows).
- XEP was installed in the *`DITA-OT-DIR`*`/plugins/org.dita.pdf2/lib` directory of the Oxygen XML Editor installation directory.

Antenna House

The Antenna House (AH Formatter) processor. If Antenna House is already installed, Oxygen XML Editor displays the detected installation path under the drop-down menu. Antenna House is considered installed if it was detected in one of the following sources:

- Environment variable set by Antenna House installation (the newest installation version will be used).
- Antenna House was added as an external FO Processor in the Oxygen XML Editor preferences pages.

To further customize the PDF output obtained from the Antenna House processor, follow these steps:

1. **Edit** the transformation scenario.
2. Open the **Parameters** tab *(on page 3297)*.
3. Add the `env.AXF_OPT` parameter and point to the Antenna House configuration file.

Related information

FO Processors Preferences *(on page 269)*

XSL-FO (Apache FOP) Processor for Generating PDF Output *(on page 1572)*

Parameters Tab (DITA-OT Transformations)

When you create a new transformation scenario *(on page 1504)* or edit an existing one *(on page 1597)*, a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Parameters** tab allows you to configure the parameters sent to the DITA-OT build file.

The table in this tab displays all the parameters that the DITA-OT documentation specifies as available for each chosen type of transformation (for example, XHTML or PDF), along with their description and current values. You can find more information about each parameter in the DITA-OT Documentation. You can also add, edit, and remove parameters, and you can use the text box to filter or search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

Depending on the type of a parameter, its value can be one of the following:

- A simple text field for simple parameter values.
- A combo box with some predefined values.
- A file chooser and an editor variable *(on page 332)* selector to simplify setting a file path as the value of a parameter.

Note:
To input parameter values at runtime, use the *ask* editor variable *(on page 334)* in the **Value** column.

Below the table, the following actions are available for managing parameters:

New

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. You can specify the **Value** of the parameter by using the **Insert Editor Variables** *(on page 332)* button or the **Browse** button. You can also use the **Open in editor** button to open the specified file in the editor panel.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Edit

Opens the **Edit Parameter** dialog box that allows you to change the value of the selected parameter or its description.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

Parameters Contributed by an Oxygen Publishing Template

Transformation parameters that are defined in an *Oxygen Publishing Template (on page 1856)* descriptor file are displayed in italics. After creating a publishing template *(on page 1864)* and adding it to the templates gallery *(on page 1701)*, when you select the template in the **Templates** tab *(on page 3291)*, the **Parameters** tab will automatically be updated to include the parameters defined in the template descriptor file.

Related Information:
DITA Open Toolkit Documentation

Feedback Tab (DITA-OT Transformations)

When you create a new transformation scenario *(on page 1504)* or edit an existing one *(on page 1597)*, a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Feedback** tab is for those who want to provide a way for users to offer feedback and ask questions in the published output and it is available for the **DITA Map WebHelp Responsive** transformation type. To add a comments component in the output, you need to use **Oxygen Feedback** to create a site configuration for the website where your WebHelp output is published and use this **Feedback** tab to instruct the transformation to install the comments component at the bottom of each WebHelp page.

When you create a site configuration in the **Oxygen Feedback** administration interface, an HTML fragment is generated during the final step of the creation process. You need to click the **Edit** button at the bottom-right of this tab to open a dialog box where you will paste the generated HTML fragment. The HTML fragment can

also be set in an **Oxygen Publishing Template** *(on page 1856)*, either as an HTML fragment extension point *(on page 1668)* or as a transformation parameter *(on page 1666)* (the `webhelp.fragment.feedback` parameter). If the fragment is specified in multiple places, the order of precedence (from highest to lowest) is:

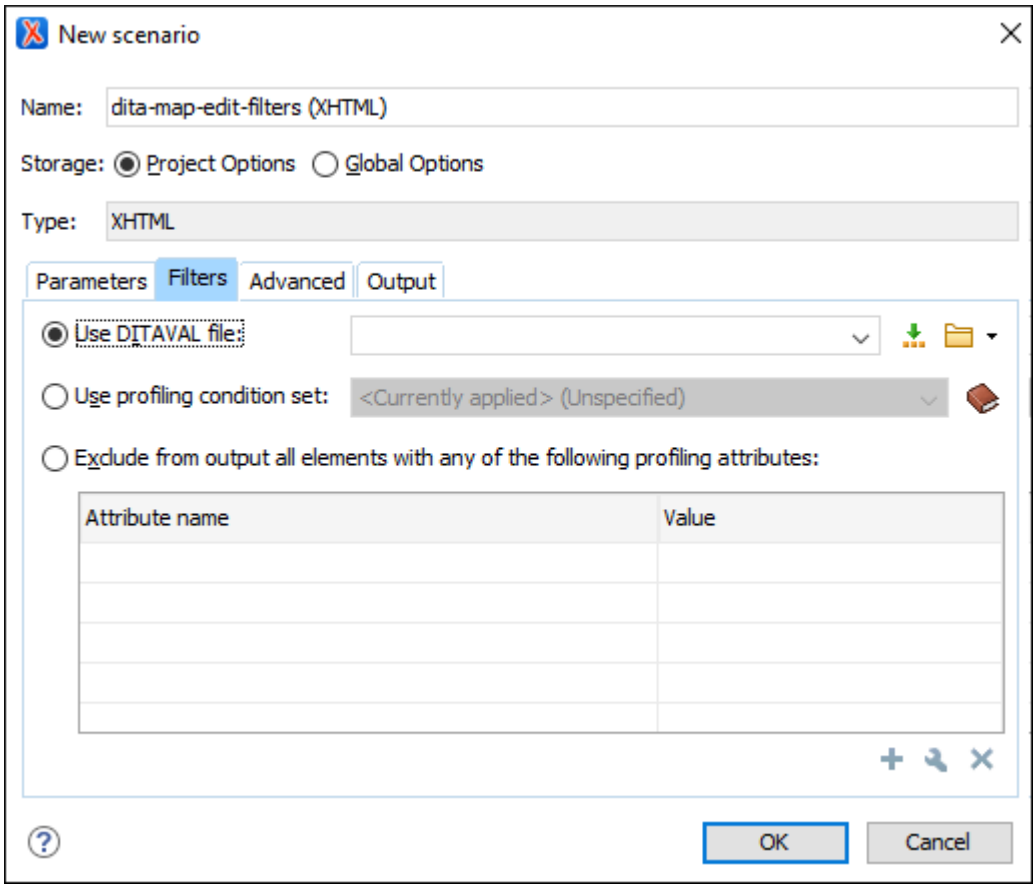
- The fragment specified directly in the **Feedback** tab.
- The fragment specified in a publishing template as an HTML fragment extension point.
- The fragment specified in a publishing template as a transformation parameter.

Filters Tab (DITA Transformations)

When you create a new transformation scenario *(on page 1504)* or edit an existing one *(on page 1597)*, a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Filters** tab allows you to add filters to remove certain content elements from the generated output.

Figure 821. Edit Filters Tab



You can choose one of the following options to define filters:

Use DITAVAL file

If you already have a *DITAVAL* file associated with the *DITA map (on page 3419)*, you can specify the file to be used when filtering content. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 332)* button, or the browsing

actions in the **Browse** drop-down list. You can find out more about constructing a *DITAVAL* file in the DITA Documentation.

> **Note:**
> If a filter file is specified in the `args.filter` parameter (in the **Parameters** tab *(on page 3297)*), the filters are combined (neither file takes precedence over the other).

Use profiling condition set

Sets the profiling condition set *(on page 3328)* that will be applied to your transformation.

Exclude from output all elements with any of the following attributes

By using the **New**, **Edit**, or **Delete** buttons at the bottom of the pane, you can configure a list of attributes (name and value) to exclude all elements that contain any of these attributes from the output.

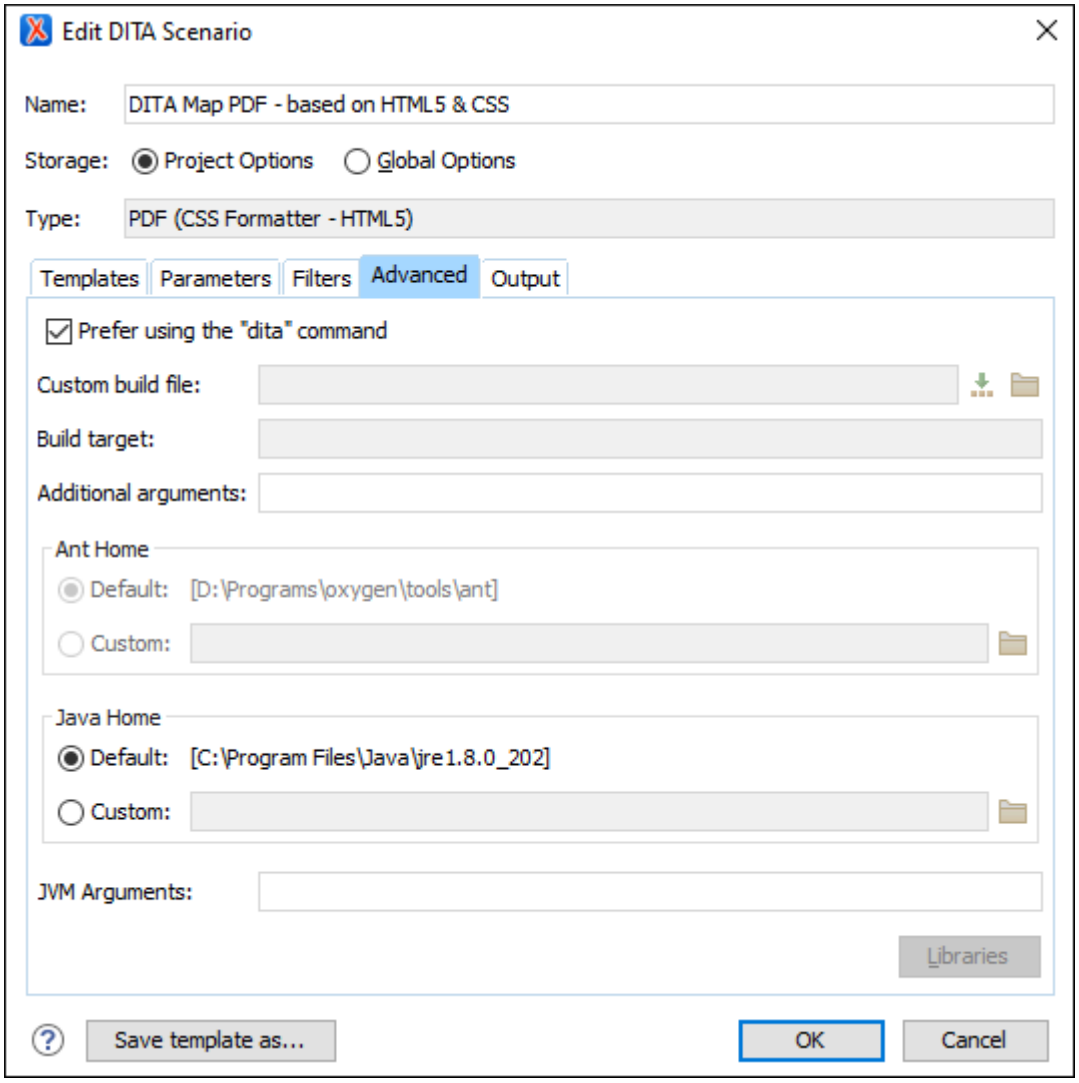
> **Note:**
> The colors and styles of the profiled content *(on page 3333)* settings are used for rendering it in **Author** mode but are not applied in the output.

Advanced Tab (DITA-OT Transformations)

When you create a new transformation scenario *(on page 1504)* or edit an existing one *(on page 1597)*, a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Advanced** tab allows you to specify advanced options for the transformation scenario.

Figure 822. Advanced Settings Tab



You can specify the following options:

Prefer using the "dita" command

When selected, Oxygen XML Editor will attempt to use the `dita.bat` executable script (`dita.sh` for macOS and Linux) that is bundled with DITA-OT to run the transformation. If not selected, the transformation will run as an ANT process. Also, when this option is selected, other options (**Custom build file**, **Build target**, **Ant Home**) become unavailable. This setting is checked by default in newly created DITA-OT transformation scenario.

Note:
Even when this option is selected, the `dita.bat` (`dita` for macOS and Linux) executable cannot be used in some cases. For example, if the DITA Map is published from a remote location or if the `fix.external.refs` parameter is enabled in the **Parameters** tab, the transformation is started as an ANT process instead of using the executable.

Custom build file

If you use a custom DITA-OT build file, you can specify the path to the customized build file. If empty, the `build.xml` file from the `dita.dir` parameter that is configured in the **Parameters** tab *(on page 3297)* is used. You can specify the path by using the text field, the **Insert Editor Variables** *(on page 332)* button, or the **Browse** button.

Build target

Optionally, you can specify a build target for the build file. If no target is specified, the default `init` target is used.

Additional Ant arguments

You can specify additional Ant-specific command-line arguments (such as `-diagnostics`).

Ant Home

You can choose between the default or custom Ant installation to run the transformation. The default path can be configured in the Ant preferences page *(on page 274)*.

Java Home

You can choose between the default or custom Java installation to run the transformation. The default path is the Java installation that is used by Oxygen XML Editor.

Note:
It may be possible that the used Java version is incompatible with the DITA Open Toolkit engine. If you encounter related errors running the transformation, consider installing a Java VM that is supported by the DITA-OT publishing engine and using it in the **Java Home** text field.

JVM Arguments

This parameter allows you to set specific parameters for the Java Virtual Machine used by Ant. When performing a large transformation, you may want to increase the memory allocated to the Java Virtual Machine. This will help avoid *Out of Memory* error messages (**OutOfMemoryError**). For example, if it is set to **-Xmx2g**, the transformation process is allowed to use a maximum 2 gigabytes of memory. If you do not specify an **-Xmx** value in this field, by default, the application will use a maximum of about a quarter of the total memory available on the machine.

Libraries

By default, Oxygen XML Editor adds libraries (as high priority) that are not transformation-dependent and also patches for certain DITA Open Toolkit bugs. You can use this button to specify additional libraries (*JAR (on page 3420)* files or additional class paths) to be used by the transformer.

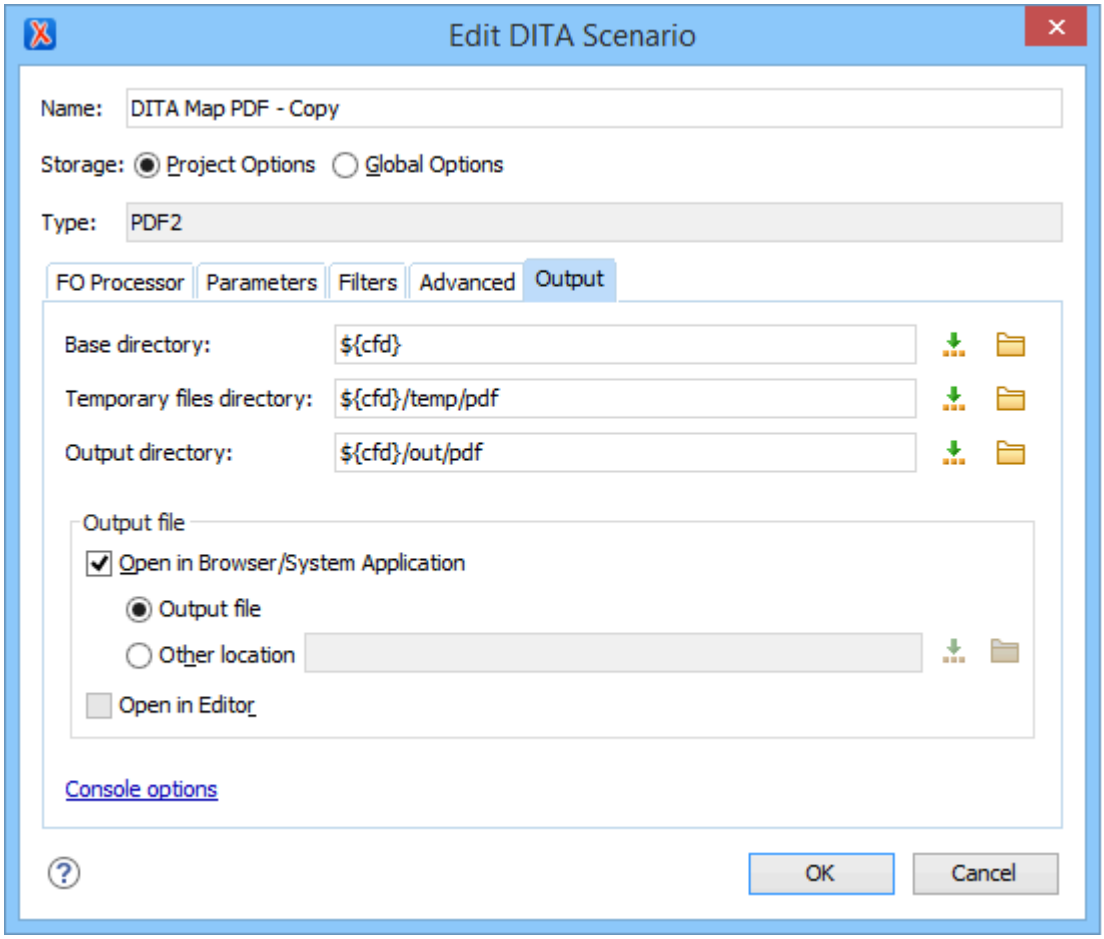
Tip:
You can specify the path to the additional libraries using wildcards (for example, `${oxygenHome}/lib/*.jar`).

Output Tab (DITA-OT Transformations)

When you create a new transformation scenario *(on page 1504)* or edit an existing one *(on page 1597)*, a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Output** tab allows you to configure options that are related to the location where the output is generated.

Figure 823. Output Settings Tab



You can specify the following parameters:

Base directory

All the relative paths that appear as values in parameters are considered relative to the base directory. The default value is the directory where the transformed map is located. You can specify the path by using the text field, the **Insert Editor Variables** *(on page 332)* button, or the **Browse** button.

Temporary files directory

This directory is used to store pre-processed temporary files until the final output is obtained. You can specify the path by using the text field, the **Insert Editor Variables** *(on page 332)* button, or the **Browse** button.

Output directory

The folder where the content of the final output is stored. You can specify the path by using the text field, the **Insert Editor Variables** *(on page 332)* button, or the **Browse** button.

> **Note:**
> If the *DITA map (on page 3419)* or topic is opened from a remote location or a ZIP file, the parameters must specify absolute paths.

Open in Browser/System Application

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows *PDF* files are often opened in *Acrobat Reader*).

> **Note:**
> To set the web browser that is used for displaying HTML/XHTML pages, go to **Options > Preferences > Global**, and set it in the **Default Internet browser** field.
>
> - **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.
> - **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the **Insert Editor Variables** *(on page 332)* button, or the **Browse** button.

Open in editor

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

At the bottom of the pane there is a link to the Console options *(on page 284)* preferences page that contains options to control the display of the console output received from the publishing engine.

Customizing DITA Transformations

You can customize the appearance of any of the output types by customizing the output transformations. There are several ways to do this:

- Most transformations are configurable by passing parameters to the transformation script. Oxygen XML Editor allows you to set parameters *(on page 3297)* on a transformation scenario and you can save and share them with others *(on page 1606)*. You can also use the **${ask}** editor variable *(on page 334)* in the **Parameters** tab to instruct Oxygen XML Editor to prompt you for a particular parameter

whenever a transformation scenario is run. You can set up multiple transformation scenarios for a given output type, allowing you to maintain several customized transformation scenarios for multiple types of output configurations.
- If you want to customize an output in a way not supported by the built-in customization options, you can create a modified version of the transformation code and execute it using a custom build file *(on page 3306)*. Sometimes the transformation code exports specific forms of extensions or customizations. You should consult the DITA Open Toolkit for the transformation type that you are interested in to see what customization options are supported. Oxygen XML Editor provides full editing and debugging support from XSLT and CSS stylesheets *(on page 2217)*, which you can use to modify transformation code.
- You can also write your own transformation code (and execute it using a custom build file *(on page 3306)*) to produce a type of output not supported by the DITA Open Toolkit. Oxygen XML Editor provides a full source editing environment for developing such transformations. You can create Oxygen XML Editor transformation scenarios to run these scripts once they are complete.

There are also many other ways to customize specific types of output generated from DITA transformations:

- **WebHelp** - For information about customizing WebHelp output, see the WebHelp Output section *(on page 1611)*.
- **PDF** - For information about customizing PDF output generated from DITA content, see XSL FO-based DITA to PDF Customization *(on page 2104)*.

Publishing Customizations

Some customizations (usually for HTML-based output), can be made simply by creating a custom CSS and they do not involve modifying the DITA-OT engine in any way. Instead, most customizations involve adding a new plugin to the DITA-OT. Here are some best practices to follow before beginning your customization:

1. Copy the bundled DITA-OT folder (usually `OXYGEN_INSTALL_DIR\frameworks\dita\DITA-OT`) to a location where you have full write access so that you have the ability to install new DITA-OT plugins *(on page 3351)*.
2. Go to **Options > Preferences > DITA**, select **Custom** for the **DITA Open Toolkit** option and set the **Location** to be the path to the location where you copied the bundled DITA-OT folder. This will allow you to upgrade the version of Oxygen XML Editor at anytime without affecting the publishing system.
3. Share that external DITA-OT folder with the rest of the team. If you are using a repository (such as Subversion or Git), you can commit the entire modified DITA-OT publishing engine as part of your project. This will allow everyone in your team to use the official changes that you made. This will also allow you to set up some kind of automatic publishing system using an open-source integration server (such as Travis CI or Jenkins).

Customizing XHTML-based Output

XHTML-based output can be modified by using a custom CSS stylesheet to override various styles. If you edit an XHTML transformation scenario *(on page 3289)*, there is a parameter called **args.css** that can be set

to point to your custom CSS and a parameter called **args.copy.css** that as long as it is set to **yes**, the CSS is copied to the output folder.

You can also create plugins to customize the XHTML-based output by adding an extra XSLT stylesheet. For for information, see: https://blog.oxygenxml.com/topics/creating-simple-dita-open-toolkit.html. A list with all DITA-OT XSLT extension points can be found here: http://www.dita-ot.org/dev/extension-points/plugin-extension-points-xslt-import.html.

Customizing WebHelp-based Output

The **DITA-OT** that comes bundled in Oxygen XML Editor includes specific plugins that provide the ability to publish DITA content to **WebHelp Responsive** *(on page 1612)* output.

For information about customizing **WebHelp Responsive** output, see Customizing WebHelp Responsive Output *(on page 1697)*.

Customizing PDF-based Output

DITA to PDF output can be customized either by creating a PDF customization folder (in this case, the DITA-OT folder will not be modified at all) or by creating a PDF customization plugin. For information about customizing DITA to PDF output, see XSL FO-based DITA to PDF Customization *(on page 2104)*.

There is also a book called DITA For Print that contains details about how to customize various aspects.

Customizing PDF Output with CSS

Oxygen XML Editor also includes a transformation scenario called **DITA Map PDF - based on HTML5 & CSS** *(on page 3278)* that is based on a *DITA-OT CSS-based PDF Publishing plugin* that allows you to convert *DITA maps (on page 3419)* to PDF using a CSS layout processor. For those who are familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with *xsl:fo* customizations. For more information about customizing PDF output using this transformation scenario, see Customization CSS *(on page 1868)*.

Related Information:
DITA Open Toolkit Documentation

Using a Custom Build File

You can use a *Custom Build File* to customize transformation scenarios.

To use a custom build file in a DITA-OT transformation, follow these steps:

1. Use the  **Configure Transformation Scenario(s)** action to open the **Configure Transformation Scenario(s)** dialog box *(on page 1600)*.
2. Select the transformation scenario and click **Edit**.
3. Go to the **Advanced** *(on page 3300)* tab and change the **Custom build file** path to point to the custom build file.

As an example, if you want to call a custom script before running the DITA-OT, your custom build file would have the following content:

```
<project basedir="." default="dist">
<!--The DITA-OT default build file-->
 <import file="build.xml"/>
 <target name="dist">
  <!-- You could run your script here -->
  <!--<exec></exec>-->
   <!--Call the DITA-OT default target-->
   <antcall target="init"/>
 </target>
</project>
```

Note:
If you use the built-in Ant 1.9.8 build tool that comes bundled with Oxygen XML Editor, it is located in the *[OXYGEN_INSTALL_DIR]*`/tools/ant` directory. Any additional libraries for Ant must be copied to the Oxygen XML Editor Ant `lib` directory.

Adding a Watermark in DITA Map to XHTML Output

To add a watermark to the XHTML output of a *DITA map (on page 3419)* transformation, follow these steps:

1. Create a custom CSS stylesheet that includes the watermark image, as in the following example:
   ```
   body {
    background-image: url(MyWatermarkImage.png);
   }
   ```
2. Edit a **DITA Map XHTML** transformation scenario and in the **Parameters** tab set the value of the `args.css` parameter as the path to your watermark image.
3. Set the value of the `args.copycss` parameter to **yes**.
4. Apply the transformation scenario.
5. Copy the watermark image in the output directory of the transformation scenario, next to the CSS file created in step 1.

Related Information:
Adding a Watermark to PDF Output *(on page 2108)*

How to Add Syntax Highlights for Codeblocks in the Output

Syntax Highlighting makes it easier to read the semantics of the structured content by displaying each type of code (language) in different colors and fonts. The application provides the ability to add syntax highlights in codeblocks for DITA to PDF or HTML-based output through the use of the `@outputclass` attribute and a variety of predefined values are available.

To provide syntax highlighting in the codeblocks that appear in the output, add the `@outputclass` attribute on the `<codeblock>` element and set its value to one of the predefined language values. The **Content Completion Assistant** offers a list of the possible values when adding the `@outputclass` attribute in **Text** mode but there are also two simple ways to set the value in **Author** mode:

- Select the `<codeblock>` element in the editor and in the **Attributes** view, click on the **Value** cell for the `@outputclass` attribute and select one of the predefined values (for example, `language-xml`).
- Select the `<codeblock>` element in the editor and use the **Alt + Enter** keyboard shortcut to open the in-place attributes editor window. Then select one of the predefined values from the **Value** drop-down menu.

The predefined values that can be selected are:

- language-json
- language-yaml
- language-xml
- language-bourne
- language-c
- language-cmd
- language-cpp
- language-csharp
- language-css
- language-dtd
- language-ini
- language-java
- language-javascript
- language-lua
- language-perl
- language-powershell
- language-php
- language-python
- language-ruby
- language-sql
- language-xquery

Attention:
It is recommended that you do not add inline elements in the codeblocks when using this `@outputclass` attribute, as it may lead to improper highlighting.

Tip:
Starting with version 24.0, the language values can also be set without using the `language-` prefix.

Example:

The following codeblock with the `@outputclass` set as `language-css`:

```
<codeblock outputclass="language-css" id="codeblock_1">@page preface-page {
 background-color:silver;
 @top-center{
  content: "Custom Preface Header";
 }
}
*[class ~= "topic/topic"][@topicrefclass ~= "bookmap/preface"] {
 page: preface-page;
}</codeblock>
```

would like this in WebHelp output:

```
@page preface-page {
 background-color:silver;
 @top-center{
  content: "Custom Preface Header";
 }
}
*[class ~= "topic/topic"][@topicrefclass ~= "bookmap/preface"] {
 page: preface-page;
}
```

Publishing with a DITA-OT Project File

The *DITA Open Toolkit* project file allows you to define all your DITA map input and filter pairs and to produce the desired output formats by applying the publishing engine over this single project file: https://www.dita-ot.org/dev/topics/using-project-files.html.

Once a DITA-OT project file is opened in the application, two predefined publishing scenarios become available in the **Configure Transformation Scenario(s)** dialog box *(on page 1600)*:

- **Publish DITA-OT Project (all deliverables)** - Runs the publishing engine and produces output for all deliverables defined in the project file.
- **Publish DITA-OT Project (select deliverable)** - Runs the publishing engine and produces output for only one deliverable specified by the end-user.

Some of the allowed transformation parameters that are relevant to the DITA-OT project file include:

- **project.file** - Specifies the path to the project file.
- **dita-ot.dir** - Specifies the directory where DITA-OT, used in transformation is installed.
- **additional.args** - Specifies the additional arguments used in transformation.
- **deliverable.id** - Specifies the id of the deliverable. This parameter is only available in the **Publish DITA-OT Project (select deliverable)** transformation.
- **jvm.args** - Specifies the JVM arguments used by the transformation for each deliverable. This can be used to increase the memory allocation used by the transformation.

  Example: To set the JVM memory allocation to 5 GB for publishing deliverables, append the following value to the existing ones:

  ```
  -Xmx5G
  ```

  If the "pdf-css-html5" (based on Chemistry PDF CSS processor) deliverable publication fails with an Out Of Memory Error, try appending the `baseJVMArgLine` parameter to the "jvm.args" parameter value. For example:

  ```
  -DbaseJVMArgLine=-Xmx5G
  ```

Tip:
When a DITA-OT project file is open in **Author** mode, there is a play button () next to the project file name. You can use this button to publish all deliverables specified in the file. While the transformation is running, the button turns into a stop button in case you need to terminate the process.

DITA Open Toolkit Project *(on page 3357)*

Dynamic Word, Excel, OpenAPI, HTML, Markdown to DITA Conversion

The publishing engine has support to dynamically convert various types of non-DITA resources to DITA while publishing. This support also enables the dynamically converted document titles for the non-DITA resources that are referenced in a DITA map to be displayed as the title of the resource in the **DITA Maps Manager**.

Attention:
These features are available with no restrictions when the publishing process is done using the default publishing engine that is bundled in **Oxygen XML Editor/Author** or if you have integrated the DITA-OT dynamic converter plugin into a custom DITA-OT distribution. However, if the publishing process is done from a command line, this feature requires an **Oxygen Publishing Engine** license.

To enable this support for a particular resource that is referenced in a DITA map, you must specify one of the following values for the `@format` attribute on the `<topicref>` element:

Word to DITA (`word-to-dita`)

Microsoft Word documents that are referenced in the DITA map using the `word-to-dita` value for the `@format` attribute get dynamically converted to DITA topics during publishing. Image references and internal links are preserved.

Example:

```
<topicref href="sample.docx" format="word-to-dita"/>
```

Excel to DITA (`excel-to-dita`)

Microsoft Excel documents that are referenced in the DITA map using the `excel-to-dita` value for the `@format` attribute get dynamically converted to DITA topics that contain one or more tables during publishing.

Example:

```
<topicref href="sample.xlsx" format="excel-to-dita"/>
```

OpenAPI to DITA (`openapi-to-dita`)

OpenAPI documents (versions 2.0, 3.0, or 3.1) in JSON or YAML format that are referenced in the DITA map using the `openapi-to-dita` value for the `@format` attribute get dynamically converted to DITA topics during publishing.

Example:

```
<topicref href="openapi.json" format="openapi-to-dita"/>
<topicref href="openapi.yaml" format="openapi-to-dita"/>
```

HTML to DITA (`html-to-dita`)

HTML documents that are referenced in the DITA map using the `html-to-dita` value for the `@format` attribute get dynamically converted to DITA topics during publishing.

Example:

```
<topicref href="sample.html" format="html-to-dita"/>
```

Markdown to DITA (`markdown`)

Markdown documents that are referenced in the DITA map using the `markdown` value for the `@format` attribute get dynamically converted to DITA topics during publishing using the support for Markdown bundled with the publishing engine by default.

Example:

```
<topicref href="sample.md" format="markdown"/>
```

Markdown to DITA (`markdown-to-dita`)

Markdown documents that are referenced in the DITA map using the `markdown-to-dita` value for the `@format` attribute get dynamically converted to DITA topics during publishing using the special conversion plugin provided by Oxygen XML Editor. The `markdown-to-dita` format conversion

is more flexible that the built-in `markdown` conversion, allowing the conversion of Markdown documents that do not have consistent heading levels.

Example:

```
<topicref href="sample.md" format="markdown-to-dita"/>
```

Resources

For more information about working with DITA-compatible resources, see the following resources:

- Video: **Integrating REST-API Content into DITA Documentation in Oxygen**
- Webinar: **Integrating Various Document Formats (OpenAPI, Word, Markdown, HTML, Excel) into DITA Documentation**

Troubleshooting DITA Transformation Problems

This section contains some topics to help you troubleshoot DITA transformation issues.

DITA Map Transformation Fails (Cannot Connect to External Location)

Problem

DITA map (on page 3419) transformation fails because it cannot connect to an external location.

Solution

The transformation is run as an external Ant process so you can continue using the application as the transformation unfolds. All output from the process appears in the **DITA Transformation** tab.

The HTTP proxy settings are used for the Ant transformation, so if the transformation fails because it cannot connect to an external location, you can check the the **Proxy** preferences page *(on page 310)*

DITA Map WebHelp Transformation Fails (Duplicate Topic References Found)

Problem

DITA Map WebHelp transformation fails with a message that indicates duplicate topic references were found.

Cause

By default the WebHelp transformation uses the `force-unique` parameter set to **true** to force the transformation to create unique output files for each instance of a resource when a map contains multiple references to a single topic. However, there are cases when this feature does not work as expected and the duplicate topic references are not handled properly.

Solution

To solve this issue, you should manually set a unique `@copy-to` attribute on any duplicate topic reference that was not handled automatically by DITA-OT:

```
<map>
...
  <topicref href="../topics/MyTopic.dita"/>
...
  <topicref href="../topics/MyTopic.dita" copy-to="../topics/MyTopic-2.dita"/>
</map>
```

DITA-OT Transformation Takes a Long Time to Process

Problem

A DITA transformation takes an extremely long time to process (over an hour, for example).

Cause

Large delays in DITA-OT processing are usually caused by intensive disk operations, CPU usage, or connections to remote websites. The DITA-OT processing is very disk-intensive, each stage takes the entire content from the transformation temporary files folder, reads it, modifies it, and then writes it back.

Solution

There are several things you can try to troubleshoot this problem:

- If you are using a shared or remote drive, it is recommended to specify a local drive for the output and temporary files directory (edit the transformation scenario and in the **Output** tab, select a local directory for **Temporary files directory** and **Output directory**).
- If you want to test if the publishing has a problem downloading remote resources, you could disable the network adapter on the computer and then try to publish. The purpose is to see if the publishing finishes without any reported error about obtaining a certain HTTP resource.
- Using DTDs instead of XML Schemas is faster. This is because of a default transformation parameter called `args.grammar.cache` that only works for DTD-based DITA topics.
- You can increase the memory available to Oxygen XML Editor *(on page 3033)*. Sometimes, just increasing the amount of memory available to the DITA-OT process may be enough to lower the time necessary for the publishing to run.
- You can enable some logging to help you determine which stage in the process is taking a long time. Edit the transformation scenario and in the **Advanced** tab, enter **logger org.apache.tools.ant.listener.ProfileLogger** in the **Additional arguments** field. Then go to **Options > Preferences > DITA > Logging** and select **Always** for the **Show console output** option.
- You could try disabling antivirus applications since the publishing process is very disk intensive and certain antivirus application might slow down the process.

- If the published DITA map is part of a larger DITA project with lots of maps and topics, references from topics in the current map to topics in other sub-projects might result in problems resolving those references. You could look in the output folder to see if the number of HTML documents match the number of DITA topics in your map.

DITA PDF Transformation Fails

Problem

The DITA to PDF transformation fails.

Cause

To generate the PDF output, Oxygen XML Editor uses the DITA Open Toolkit. This process sometimes results in errors. For information about some of the most common errors, see DITA PDF Processing Common Errors *(on page 3314)*.

Solution

If your transformation fails, you can detect some of the problems that caused the errors by running the **Validate and Check for Completeness** action *(on page 3118)*. Depending on the options you select when you run it, this action reports errors such as topics referenced in other topics but not in the *DITA map (on page 3419)*, broken links, and missing external resources.

You can analyze the **Results** tab of the DITA transformation and search for messages that contain text similar to `[fop] [ERROR]`. If you encounter this type of error message, edit the transformation scenario you are using and set the **clean.temp** parameter to **no** and the **retain.topic.fo** parameter to **yes**. Run the transformation, go to the temporary directory of the transformation, open the `topic.fo` file and go to the line indicated by the error. Depending on the XSL FO context try to find the DITA topic that contains the text that generates the error.

If none of the above methods helps you, go to **Help > About > Components > Frameworks** and check what version of the DITA Open Toolkit you are using. Copy the whole output from the DITA-OT console output and either report the problem on the DITA User List or send it to support@oxygenxml.com.

Related Information:
How to Enable Debugging for FO Processor Transformations *(on page 1575)*

DITA PDF Processing Common Errors

There are cases when the PDF processing fails when trying to publish DITA content to a PDF file. This topic lists some of the common problems and possible solutions.

Problem: Cannot Save PDF

The FO processor cannot save the PDF at the specified target. The console output contains messages like this:

```
[fop] [ERROR] Anttask - Error rendering fo file:
C:\samples\dita\temp\pdf\oxygen_dita_temp\topic.fo
<Failed to open C:\samples\dita\out\pdf\test.pdf>
Failed to open samples\dita\out\pdf\test.pdf
.............
[fop] Caused by: java.io.FileNotFoundException:
C:\Users\default\Desktop\bev\out\pdf\test.pdf
(The process cannot access the file because it is being used by another process)
```

Solution: Cannot Save PDF

Such an error message usually means that the PDF file is already opened in a PDF reader application. The solution is to close the open PDF before running the transformation.

Problem: Table Contains More Cells Than Defined in Colspec

One of the DITA tables contains more cells in a table row than the defined number of `<colspec>` elements. The console output contains messages like this:

```
[fop] [ERROR] Anttask - Error rendering fo file:
D:\projects\eXml\samples\dita\flowers\temp\pdf\oxygen_dita_temp\topic.fo
<net.sf.saxon.trans.XPathException: org.apache.fop.fo.ValidationException:
The column-number or number of cells in the row overflows the number of
fo:table-columns specified for the table.
(See position 179:-1)>net.sf.saxon.trans.XPathException:
org.apache.fop.fo.ValidationException: The column-number or number of cells
in the row overflows the number of fo:table-columns specified for the table.
(See position 179:-1)
[fop]     at org.apache.fop.tools.anttasks.FOPTaskStarter.renderInputHandler
(Fop.java:657)
[fop]     at net.sf.saxon.event.ContentHandlerProxy.startContent
(ContentHandlerProxy.java:375)
.............
[fop] D:\projects\samples\dita\flowers\temp\pdf\oxygen_dita_temp\topic.fo ->
D:\projects\samples\dita\flowers\out\pdf\flowers.pdf
```

Solution: Table Contains More Cells Than Defined in Colspec

To resolve this issue, correct the `@colspec` attribute on the table that caused the issue. To locate the table that caused the issue:

1. Edit the transformation scenario and set the parameter `clean.temp` to `no`.
2. Run the transformation, open the `topic.fo` file in Oxygen XML Editor, and look in it at the line specified in the error message `(See position 179:-1)`.
3. Look around that line in the `XSL-FO` file to find relevant text content that you can use (for example, with the **Find/Replace in Files** action in the **DITA Maps Manager** view *(on page 3073)*) to find the original DITA topic where the table was generated.

Problem: Broken Link

There is a broken link in the generated `XSL-FO` file. The PDF is generated but contains a link that is not working. The console output contains messages like this:

```
[fop] 1248 WARN [ main ] org.apache.fop.apps.FOUserAgent -
Page 6: Unresolved ID reference "unique_4_Connect_42_wrongID" found.
```

Solution: Broken Link

To resolve this issue:

1. Use the  **Validate and Check for Completeness** action available in the **DITA Maps Manager** view *(on page 3073)* to find such problems.
2. If you publish to PDF using a *DITAVAL* filter, select the same DITAVAL file in the **DITA Map Completeness Check** dialog box.
3. If the  **Validate and Check for Completeness** action does not discover any issues, edit the transformation scenario and set the `clean.temp` parameter to `no`.
4. Run the transformation, open the `topic.fo` file in Oxygen XML Editor, and search for the *unresolved ID references* (for example: `unique_4_Connect_42_wrongID`).
5. Look in the `XSL-FO` file to find relevant text content that you can use (for example, with the **Find/Replace in Files** action in the **DITA Maps Manager** view *(on page 3073)*) to find the original DITA topic where the table was generated.

How to Enable Debugging for FO Processor Transformations *(on page 1575)*

DITA to CHM Transformation Fails - Cannot Open File

Problem

The DITA to CHM transformation fails with the following error: `[exec] HHC5010: Error: Cannot open "fileName.chm". Compilation stopped.`

Cause

This error occurs when the CHM output file is opened and the transformation scenario cannot rewrite its content.

Solution

To solve this issue, close the CHM help file and run the transformation scenario again.

Tip:
It is a good practice to validate the *DITA map (on page 3419)* before executing the transformation scenario. To do so, run the **Validate and Check for Completeness** action *(on page 3118)*. Depending on the selected options, it will report detected errors, such as topics referenced in other topics (but not in the *DITA map*), broken links, and missing external resources.

Related Information:
DITA Map CHM (Compiled HTML Help) Transformation *(on page 3283)*

DITA to CHM Transformation Fails - Compilation Failed

Problem

The DITA to CHM transformation fails with the following error: `[exec] HHC5003: Error: Compilation failed while compiling fileName`.

Cause 1

One possible cause for this error is that the processed file does not exist.

Solution 1

To solve this issue, fix the file reference before executing the transformation scenario again.

Cause 2

Another possible cause for this error is that the processed file has a name that contains space characters.

Solution 2

To solve the issue, remove any spacing from the file name and run the transformation scenario again.

Tip:
It is a good practice to validate the *DITA map (on page 3419)* before executing the transformation scenario. To do so, run the **Validate and Check for Completeness** action *(on page 3118)*. Depending on the selected options, it will report detected errors, such as topics referenced in other topics (but not in the *DITA map*), broken links, and missing external resources.

Related Information:
DITA Map CHM (Compiled HTML Help) Transformation *(on page 3283)*

Solving DITA Transformation Errors

If a DITA transformation results in errors or warnings, the information is displayed in the message panel at the bottom of the editor. The information includes the severity, description of the problem, the name of the resource, and the path of the resource.

To help prevent and solve DITA transformation problems, follow these steps:

1. Validate the *DITA map (on page 3118)* by using the  **Validate and Check for Completeness** action that is available on the **DITA Maps Manager** *(on page 3073)* toolbar and in the **DITA Maps** menu.
2. If this action results in validation errors, solve them prior to executing the transformation. Also, you should pay attention to the warning messages because they may identify problems in the transformation.
3. Run the DITA transformation scenario *(on page 1530)*.
4. If the transformation results in errors or warnings, they are displayed in the **Results** panel *(on page 558)* at the bottom of the editor. The following information is presented to help you troubleshoot the problems:
    - **Severity** - The first column displays the following icons that indicate the severity of the problem:
        - **Informational** - The transformation encountered a condition of which you should be aware.
        - **Warning** - The transformation encountered a problem that should be corrected.
        - **Error** - The transformation encountered a more severe problem, and the output is affected or cannot be generated.
    - **Info** - Click the **See More** icon to open a web page that contains more details about DITA-OT error messages.
    - **Description** - A description of the problem.
    - **Resource** - The name of the transformation resource.
    - **System ID** - The path of the transformation resource.
5. Use this information or other resources from the online DITA-OT community to solve the transformation problems before re-executing the transformation scenario.
6. If you need to contact the *Oxygen* technical support team, they will need you to send the entire transformation scenario execution log. To obtain it:
    a. Go to the **Options > Preferences > DITA** preferences page and set the **Show console output** option to **Always**.
    b. Execute the transformation scenario again. The console output messages are displayed in the **DITA-OT** view.
    c. Copy the entire log, save it in a text file, then send it to the *Oxygen* technical support team.
    d. After your issue has been solved, go back to the **Options > Preferences > DITA** preferences page and set the **Show console output** option to **When build fails**.

Troubleshooting DITA Transformation Problems *(on page 3312)*

DITA Profiling / Conditional Text

DITA offers support for conditionally profiling content by using profiling attributes. With Oxygen XML Editor, you can define values for the DITA profiling attributes and they can be easily managed to filter content in the published output. You can switch between profile sets to see how the edited content looks like before publishing. The profiling configuration can also be shared between content authors through the project file and there is no need for coding or editing configuration files.

Oxygen XML Editor includes a **Attributes and Condition Sets** preferences page *(on page 195)* where you can create and manage profiling attributes and condition sets. Oxygen XML Editor also offers convenient support for customizing and controlling profiling attribute values with a subject scheme *(on page 3337)* or DITAVAL file *(on page 3342)*.

Profiling Attributes

You can profile content elements or map elements by adding one or more of the default DITA profiling attributes (`@product`, `@platform`, `@audience`, `@rev`, `@props`, and `@otherprops`). You can also create your own custom profiling attributes and profiling condition sets. The profiling attributes may contain one or more tokens that represent conditions to be applied to the content when a publication is built.

For example, you could define a section of a topic that would only be included for a publication related to the Windows platform by adding the `@platform` profiling attribute:

```
<section platform="windows">
```

For information about creating and editing profiling attributes, see Creating and Editing Profiling Attributes in DITA *(on page 3320)* (for information about sharing them, see Sharing Profiling Attribute Configurations *(on page 3323)*).

Profiling Conditions

DITA allows you to conditionally profile parts of a topic so that certain parts of the topic are displayed when certain profiling conditions are set. Profiling conditions can be set both within topics and in maps. When set in a topic, they allow you to suppress an element (such as paragraph), step in a procedure, item in a list, or even a phrase within a sentence. When set in a map, they allow you to suppress an entire topic or group of topics. You can then create a variety of publications from a single map by applying profiling conditions to the build.

For information about creating and editing condition sets, see Creating and Editing Profiling Condition Sets in DITA *(on page 3326)* (for information about sharing them, see Sharing Condition Set Configurations *(on page 3328)*).

Resources

For more information about DITA profiling, see the following resources:

- **Webinar: Working with DITA in Oxygen - Basic Profiling and Reuse Strategies**
- **Webinar: Working with DITA in Oxygen - Advanced Profiling and Reuse Strategies**

Creating and Editing Profiling Attributes in DITA

You can filter DITA content or the structure of a document by using profiling attributes or profiling conditions sets *(on page 3326)*.

Defining Profiling Attributes for DITA Content

To create or edit profiling attributes for filtering DITA content, follow these steps:

1. If you are creating a new attribute, make sure the attribute is already defined in the document DTD or schema before continuing with the procedure.

   > **Tip:**
   > For less technical users who do not want to create attribute specializations in DTD/XML Schema, you may want to use profiling attribute groups *(on page 3335)* instead (use an existing profiling attribute with sub-attributes).

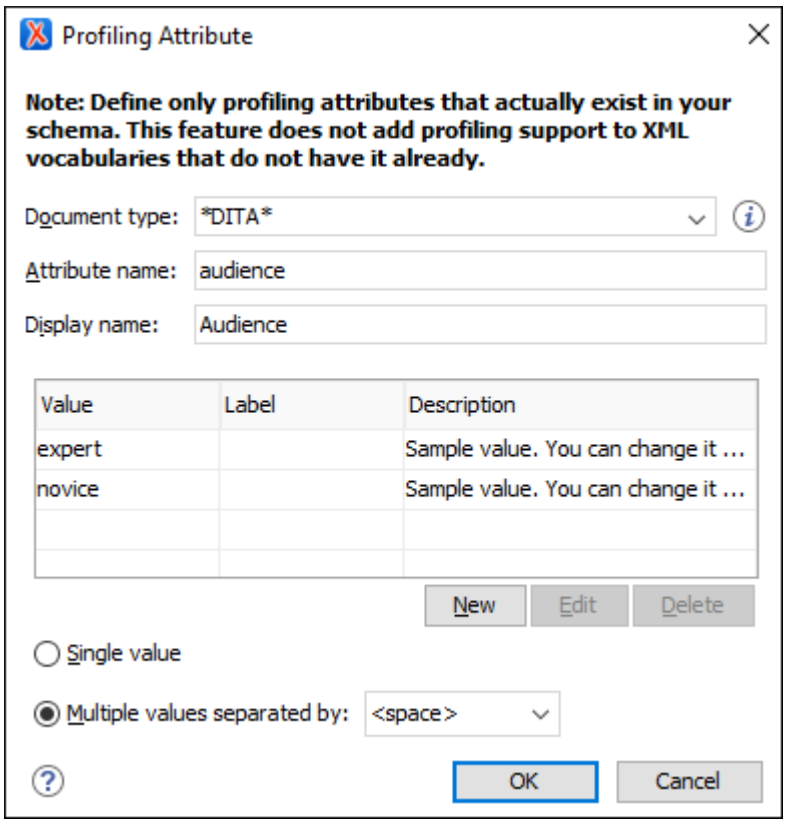
2. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Editor > Edit modes > Author > Profiling / Conditional Text > Attributes and Condition Sets**.

   > **Information:**
   > The **Profiling Attributes** section *(on page 196)* is used to define the attributes and their values. For DITA documents, the default attributes are included (`@audience`, `@platform`, `@product`, `@props`, `@otherprops`, and `@rev`), but if a *Subject Scheme Map (on page 3337)* is used for profiling your content, you will see the attributes defined in your *subject scheme map* instead.

3. To add new attributes and values, click the **New** button at the bottom of the **Profiling Attributes** table. To customize existing attributes and their values, select an attribute and click the **Edit** button.

   Step Result: In either case, this opens a **Profiling Attribute** configuration dialog box where you can define attributes that exist in your schema.

Figure 824. Profiling Attribute Dialog Box



The following options are available in this dialog box:

Document type

Select the document type (*framework (on page 3420)*).

> **Tip:**
> You can use the `*` or `?` wildcards in this combo box. For example, `DITA*` would match any document type that starts with *"DITA"*. You can also specify multiple document types by using commas to separate them.

Attribute name

The name of the profiling attribute.

Display name

This optional field is used for descriptive rendering in profiling dialog boxes.

Attribute Values Table

This table displays information about the values for the profiling attribute. You can configure them by using the buttons at the bottom of the table (**New**, **Edit**, **Delete**).

The columns are as follows:

- **Value** - The attribute value. You can also define profiling attribute groups using the following format: `ParentAttrValue(SubAttrValue1 SubAttrValue2)`. For more information, see Conditional Profiling Attribute Groups *(on page 3335)*.
- **Label** - You can specify a label for the attribute value that will be rendered as its name in various components in **Author** mode (**Edit Profiling Attributes** dialog box *(on page 3323)*, **Condition Set** dialog box *(on page 3326)*, **Profiling** tab in the **Edit Properties** dialog box *(on page 3114)*, **DITA Maps Manager** *(on page 3073)*). If the **Label** is not specified, the **Value** will be used as its rendered name.
- **Description** - A description for the attribute value that will be displayed in this table.

Single value

Select this option if you want the attribute to only accept a single value.

Multiple values separated by

Select this option if you want the attribute to accept multiple values, and you can choose the type of delimiter to use. You can choose between *space*, *comma*, and *semicolon*, or you can enter a custom delimiter in the text field. A custom delimiter must be supported by the specified document type. For example, the DITA document type only accepts spaces as delimiters for attribute values.

4. After defining or configuring the attributes and their values according to your needs, click **OK** to confirm your selections and close the **Profiling Attributes** configuration dialog box.
5. Click **Apply** to save the changes.

Result: You should see your changes in the **Profiling Attribute** table.

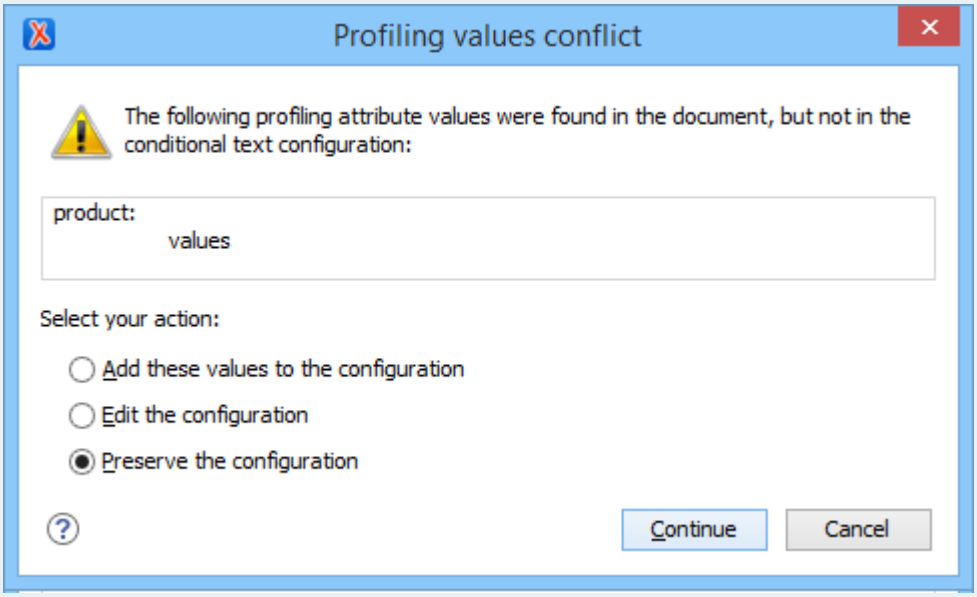
You can also use the **Profiling Condition Sets** section to apply more complex filters on your DITA content.

Adding Profiling Attribute Values Directly in a Document

You can add values directly to the existing profiling attributes in a document using the In-Place Attributes Editor *(on page 619)* in **Author** mode, the **Attributes** view *(on page 638)*, or in the source code in **Text** mode. However, this just adds them to the document and does not change the conditional text configuration. If you invoke the **Edit Profiling Attributes** action (from the contextual menu in **Author** mode) on the new value, the **Profiling Values Conflict** dialog box will appear and it includes an **Add these values to the configuration** action that will automatically add the new value to the particular profiling attribute. It also includes an **Edit the configuration** action that opens the **Attributes and Condition Sets** preferences page *(on page 195)* where you can edit the profiling configuration.

Note:
If the **Allow contributing extra profiling attribute values** option *(on page 197)* is not selected in the **Attributes and Condition Sets** preferences page, the **Profiling Values Conflict** dialog box will never appear, so this automatically adding value not be possible.

Figure 825. Profiling Values Conflict Dialog Box



Sharing Profiling Attribute Configurations

Your profiling configuration can be shared with other users through a project file. If you select **Project Options** *(on page 3423)* at the bottom of the **Profiling/Conditional Text** preferences page, your configuration is stored in the project file and can be shared with others. For instance, if your project file is saved on a version control system (such as SVN, CVS, or Source Safe) or in a shared folder, your team will have the same option configuration that you stored in the project file.

For more information about sharing project files, see Sharing a Project - Team Collaboration *(on page 425)*.

Related Information:

Applying Profiling Attributes in DITA *(on page 3323)*

Applying Profiling Condition Sets in DITA *(on page 3328)*
Showing and Filtering Profiled Content in DITA *(on page 3330)*
Customizing Colors and Styles for Rendering Profiling in Author Mode *(on page 3333)*
Conditional Profiling Attribute Groups *(on page 3335)*
Filtering Profiling Values with a DITAVAL File *(on page 3342)*

Applying Profiling Attributes in DITA

Profiling attributes are applied on element nodes. You can apply profiling attributes on a text fragment (it will automatically be wrapped into a phrase-type element), on a single element, or on multiple elements at the same time. If there is no selection in your document, the profiling attributes are applied on the element at the cursor position.

You can apply defined DITA profiling attributes *(on page 3320)* as follows:

DITA Topics

To profile DITA topics, right-click a topic reference in the **DITA Maps Manager** *(on page 3073)*, select **Edit Properties** from the contextual menu, go to the **Profiling** tab, and select the appropriate values.

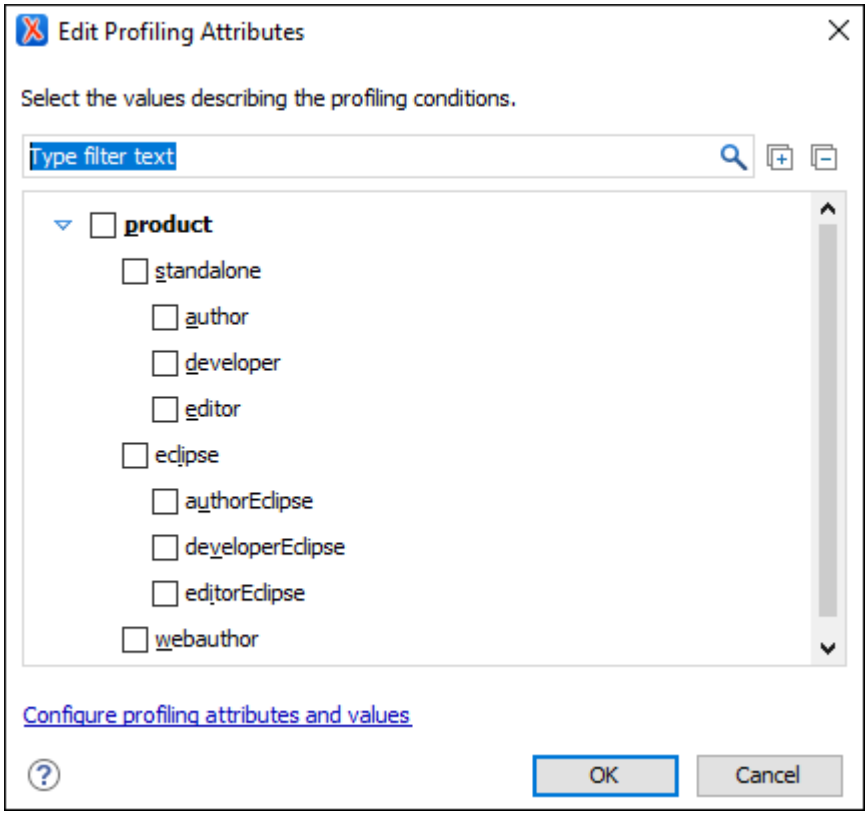
DITA Content

To profile DITA content in **Author** mode, highlight the content and select **Edit Profiling Attributes** from the contextual menu and select the appropriate values in the **Edit Profiling Attributes** dialog box.

DITA Elements

To profile specific XML elements in **Author** mode, position the cursor inside the element, right-click, select **Edit Profiling Attributes** (you can also right-click the element in the *breadcrumb (on page 612)* or **Outline** *(on page 549)* view), and select the appropriate values in the **Edit Profiling Attributes** dialog box. You can also use the **Attributes** view *(on page 638)* to set the profiling attributes on the element at the current cursor position.

Figure 826. Edit Profiling Attributes Dialog Box



The profiling attributes, and their potential values, that appear in this dialog box depend on what has been configured in Oxygen XML Editor. If you have a large list of profiling attributes, you can use the text filter field to search for attributes or values, and you can expand or collapse attributes by using the **Expand All**/**Collapse All** buttons to the right of the text filter or the arrow button to the left of the profiling attribute name.

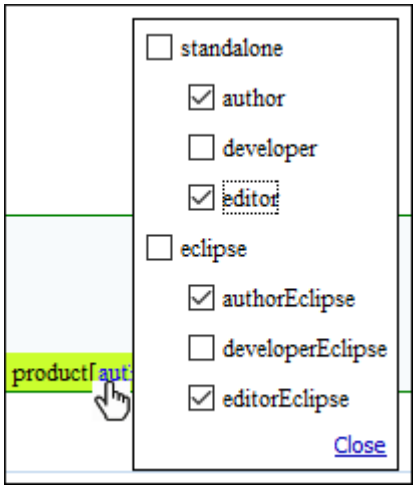
The attributes and values that appear in the dialog box are determined as follows:

- If your *root map (on page 3424)* references a DITA *subject scheme map (on page 3424)* that defines values for the profiling attributes *(on page 3337)*, those values are used. Oxygen XML Editor collects all the profiling values from the *subject scheme map* that is referenced in the map that is currently opened in the **DITA Maps Manager** *(on page 3073)* (or set as the *root map (on page 3090)*). In the image above *(on page 3324)* (taken from the Oxygen XML Editor documentation project), you see values for eight products. They are the only values that are defined in the *subject scheme map* and thus, are the only ones that appear in the dialog box.
- If you have defined profiling attribute values *(on page 3320)* for the DITA document type in the **Attributes and Condition Sets** preferences page *(on page 195)* and you store them at project-level *(on page 3423)*, those values are displayed in the dialog box.
- If you have defined profiling attribute values *(on page 3320)* for the DITA document type in the **Attributes and Condition Sets** preferences page *(on page 195)* and you store them at global-level *(on page 3420)*, those values are displayed in the dialog box.
- If you have defined profiling attribute values *(on page 3320)* for the DITA document type in the **Attributes and Condition Sets** preferences page *(on page 195)*, those values are displayed in the dialog box.
- Otherwise, a generic default set of profiling attributes and values are available.

The attribute names and values selected in the **Edit Profiling Attributes** dialog box are set on the elements contained in the profiled fragment. If you only select a fragment of content (rather than the entire element), this fragment is wrapped in phrase-type elements where the profiling attributes are set.

If the **Show Profiling Attributes** option *(on page 691)* (available in the **Profiling / Conditional Text** toolbar menu) is selected, a green border is painted around profiled text in the **Author** mode and all profiling attributes set on the current element are listed at the end of the highlighted block. To edit the attributes of a profiled fragment, click one of the listed attribute values. A form control pops up and allows you to add or remove attribute values.

Figure 827. Profiling Attribute Value Form Control Pop Up



Related Information:

Creating and Editing Profiling Attributes in DITA *(on page 3320)*

Applying Profiling Condition Sets in DITA *(on page 3328)*
Showing and Filtering Profiled Content in DITA *(on page 3330)*
Customizing Colors and Styles for Rendering Profiling in Author Mode *(on page 3333)*

Creating and Editing Profiling Condition Sets in DITA

Multiple profiling attributes can be aggregated into a profiling condition set that allows you to apply more complex filters on the document content. In DITA, profiling conditions can be set within both topics and in maps. When set in a topic, you can filter an element (such as paragraph), step in a procedure, item in a list, or even a phrase within a sentence. When set in a map, you can filter an entire topic or group of topics.

Creating Profiling Condition Sets

To create a new profiling condition set, follow these steps:

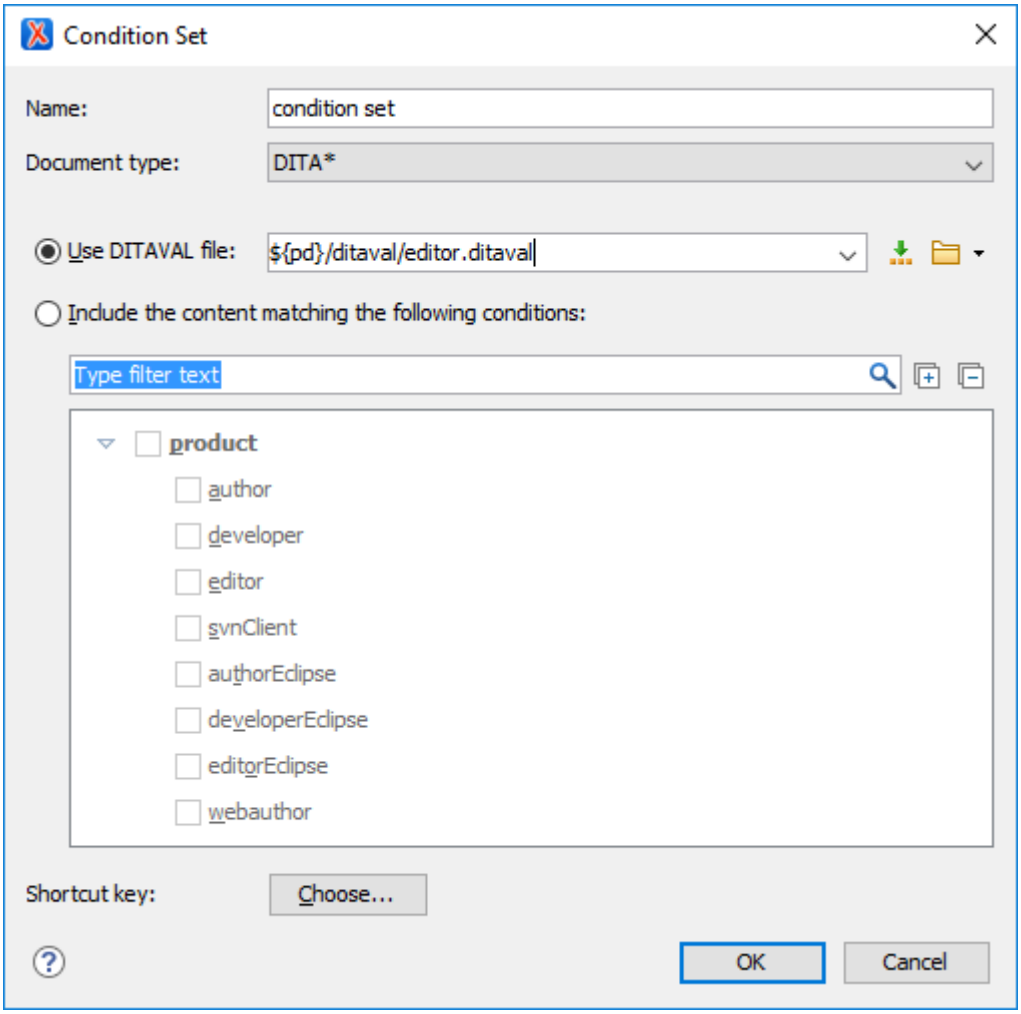
1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Editor > Edit modes > Author > Profiling/Conditional Text > Attributes and Condition Sets**.

   Information:
   The **Profiling Condition Sets** section *(on page 197)* is used to define condition sets.

2. To add new condition set, click the **New** button at the bottom of the **Profiling Condition Sets** table. To customize existing condition sets, select an existing condition set and click the **Edit** button.

   Step Result: In either case, this opens a **Condition Set** configuration dialog box where you can define attributes that exist in your schema.

Figure 828. Condition Set Configuration Dialog Box



The following options are available in this dialog box:

Name

The name of the new condition set.

Document type

Select the document type (*framework (on page 3420)*) that has profiling attributes defined.

Use DITAVAL file

For DITA projects, select this option if you want the *Profiling Condition Set* to reference a DITAVAL file *(on page 3342)*. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 332)* button, or the browsing actions in the **Browse** drop-down list.

Include the content matching the following conditions

You can select this option to define the combination of attribute values for your condition set by selecting the appropriate checkboxes for the values you want to be included in this

particular condition set. If you have defined a lot of profiling attributes, you can use the **filter** text field to search for specific conditions.

Shortcut key

You can click the **Choose** button to open a dialog box that allows you to define a shortcut key for this particular condition set. You can then use that shortcut key anytime you want to select this condition set to filter content.

3. After defining or configuring the condition sets according to your needs, click **OK** to confirm your selections and close the **Condition Set** configuration dialog box.
4. Click **Apply** to save the condition set.

Sharing Condition Set Configurations

Your condition set configuration can be shared with other users through a project file. If you select **Project Options** *(on page 3423)* at the bottom of the **Profiling/Conditional Text** preferences page, your configuration is stored in the project file and can be shared with others. For instance, if your project file is saved on a version control system (such as SVN, CVS, or Source Safe) or in a shared folder, your team will have the same option configuration that you stored in the project file.

For more information about sharing project files, see Sharing a Project - Team Collaboration *(on page 425)*.

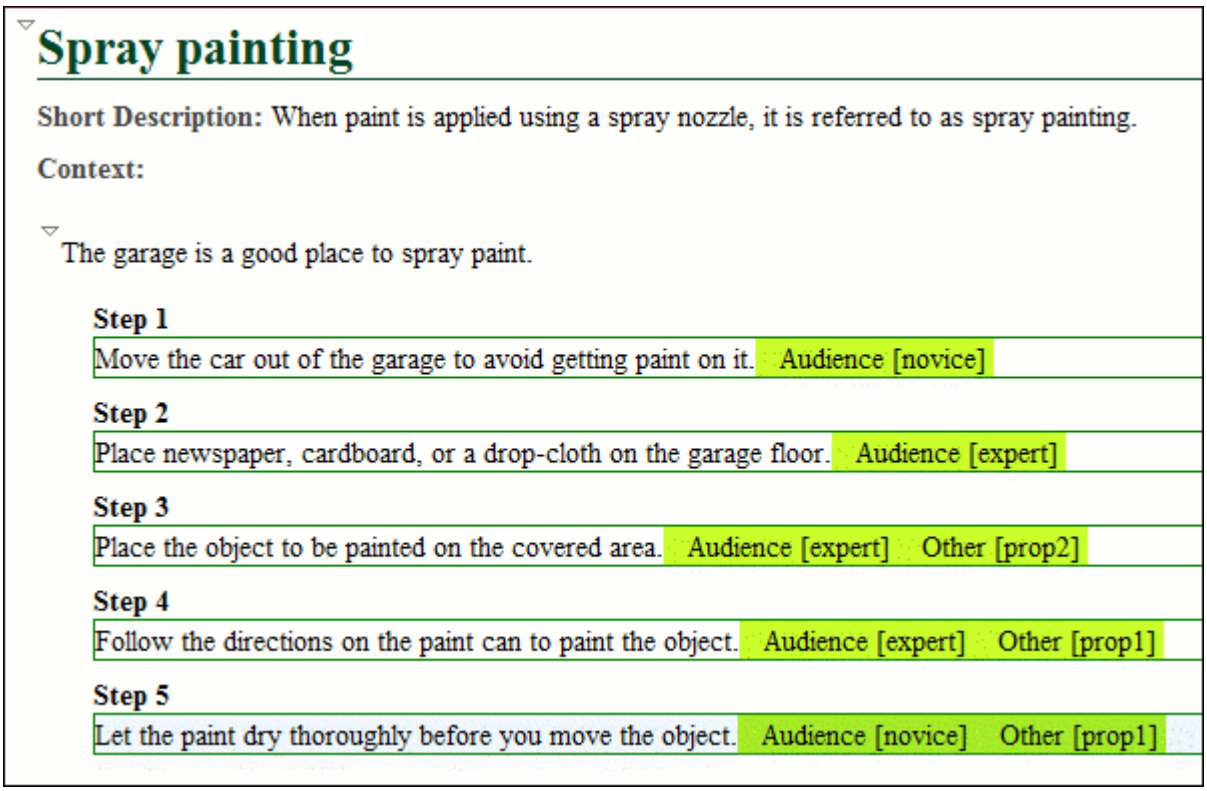
Applying Profiling Condition Sets in DITA

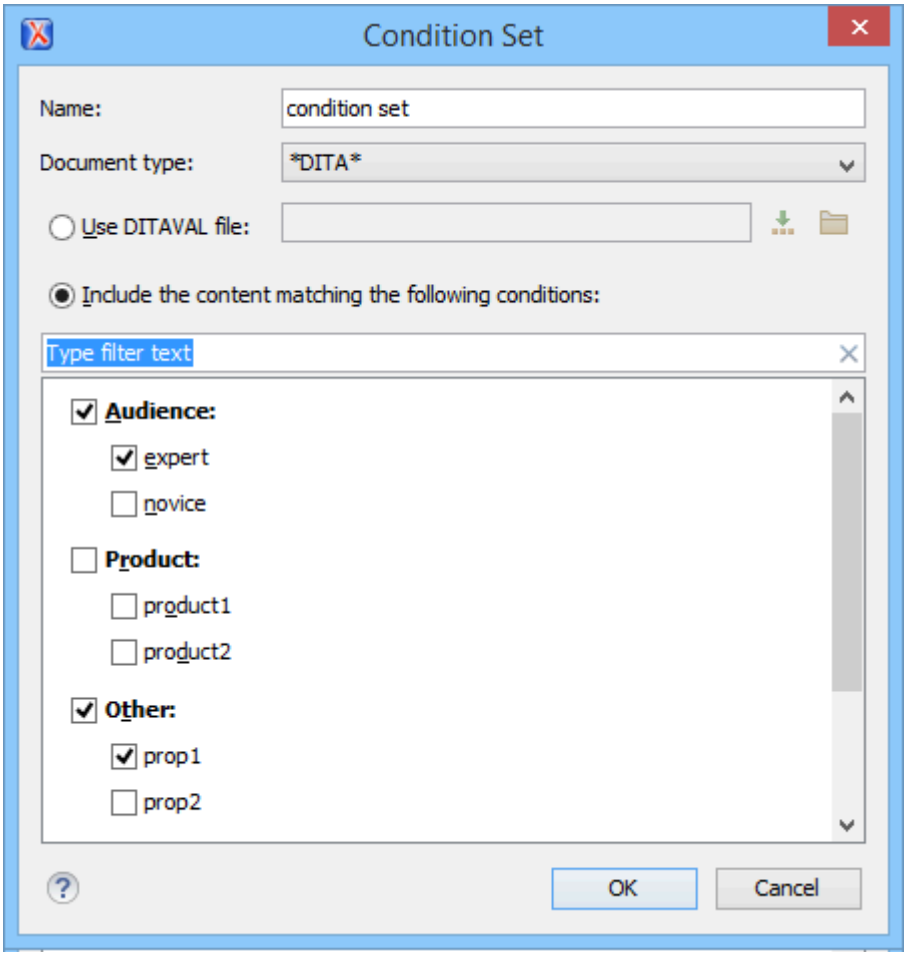
All defined Profiling Condition Sets *(on page 3326)* are available as shortcuts in the **Profiling / Conditional Text** toolbar menu *(on page 691)*. Select a menu entry to apply the condition set. The filtered content is then grayed-out in the **Author** mode, **Outline** view *(on page 549)*, and **DITA Maps Manager** view *(on page 3073)*. Your selection will also be used as the default condition set *(on page 3345)* in transformation scenarios (this can be changed in the **Filters** tab). An element is filtered-out when one of its attributes is part of the condition set and its value does not match any of the values covered by the condition set.

EXAMPLE:

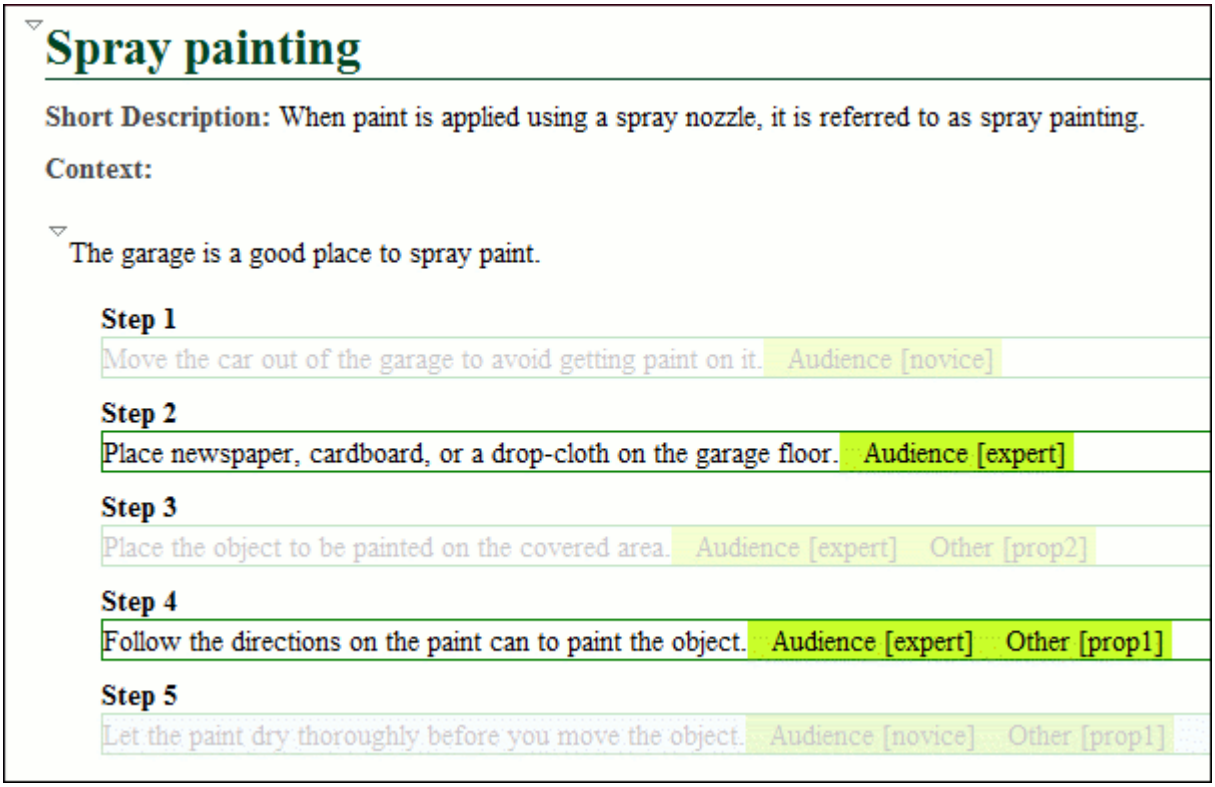
Suppose that you have the following document:



If you apply the following condition set, it means that you want to filter out the content to only include content profiled with the `expert` value for the `@audience` attribute and content that has the *prop1* value for the `@other` attribute.



This is how the document looks in **Author** mode after you apply the condition set:



Related Information:

Creating and Editing Profiling Condition Sets in DITA *(on page 3326)*

Customizing Colors and Styles for Rendering Profiling in Author Mode *(on page 3333)*

Showing and Filtering Profiled Content in DITA

You can visualize the effect of profiling content by using the profiling tools in the **Profiling/Conditional Text** drop-down menu that is located on the **DITA Maps Manager** *(on page 3073)* toolbar and on the main toolbar. This drop-down menu includes the following filtering options:

Show Profiling Colors and Styles

Select this option to show colors and styles for profiled content in **Author** mode and the **DITA Maps Manager** *(on page 3073)*. You can configure the colors and styles or specify whether or not this option is selected by default in the **Profiling/Conditional Text > Colors and Styles** preferences page *(on page 197)*.

Show Profiling Attributes

Select this option to display the values of the profiling attributes at the end of profiled content in **Author** mode and next to the nodes in the **DITA Maps Manager** *(on page 3073)*. You can specify

whether or not this option is selected by default in the **Profiling/Conditional Text** preferences page *(on page 195)*.

Show Excluded Content

Controls whether the content filtered out by a particular condition set is hidden or grayed-out in **Author** mode, the **DITA Maps Manager** *(on page 3073)*, and the **Outline** *(on page 549)* view. When this option is selected and a condition set is selected in this drop-down menu *(on page 3331)*, the filtered content is grayed-out. If this option is not selected and a condition set is selected in this drop-down menu *(on page 3331)*, the filtered content is hidden. You can specify whether or not this option is selected by default in the **Profiling/Conditional Text** preferences page *(on page 195)*.

Choose Condition Set (Available if more than 15 condition sets are defined)

This option is available if you have more than 15 conditions sets defined. It opens a dialog box that makes it easier to find and select condition sets that are not displayed in this drop-down menu.

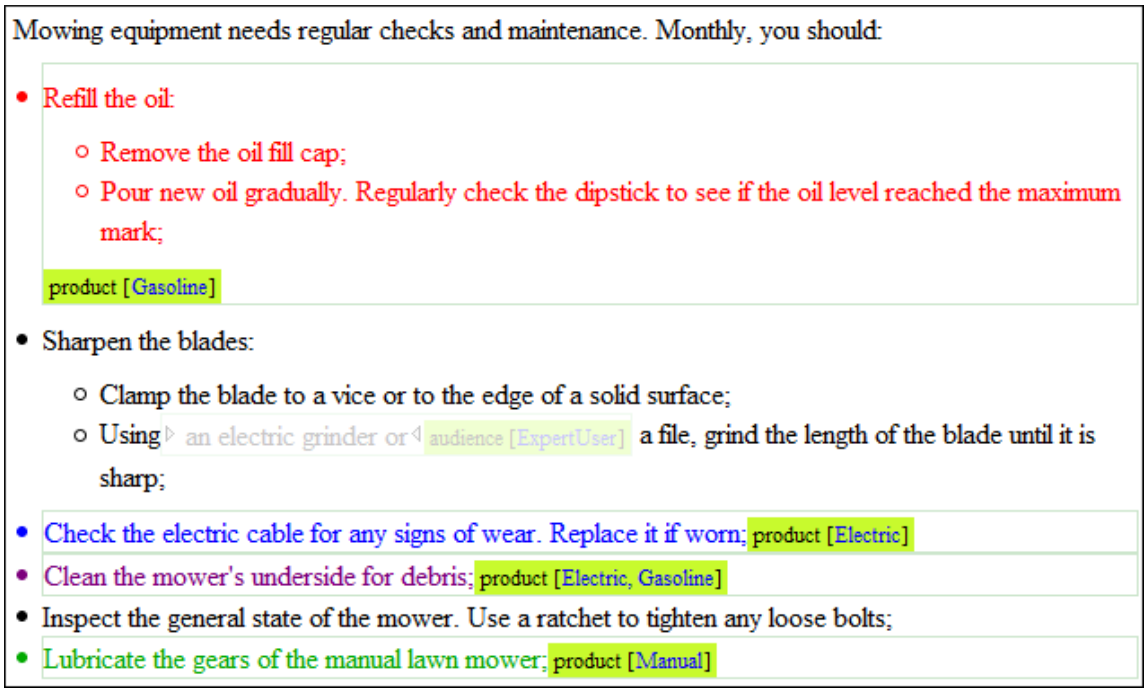
List of Defined Condition Sets

Up to 15 defined condition sets are listed and you can toggle each one of them on to filter the content in **Author** mode and the **DITA Maps Manager** *(on page 3073)* to only show content that will appear in the output for that particular condition set. If there are more than 15 defined condition sets, the rest of them can be accessed in the **More** submenu or by using the **Choose Condition Set** option *(on page 3331)* to access a dialog box that presents all of them.

Profiling Settings

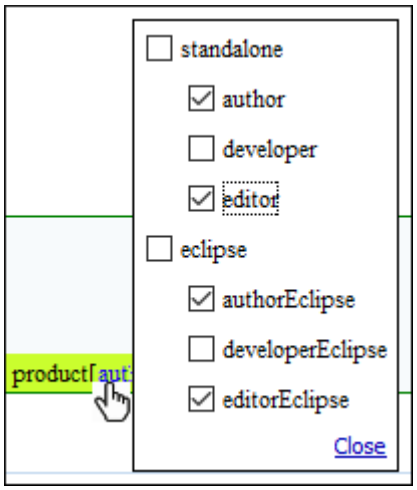
Opens the **Attributes and Condition Sets** preferences page *(on page 195)* where you can add and edit profiling attributes and condition sets.

Figure 829. Example: Profiling Controls in Author Mode



If the **Show Profiling Attributes** option is selected, a green border is painted around profiled text in the **Author** mode. Also, all profiling attributes set on the current element are listed at the end of the highlighted block and in its tooltip message. To edit the attributes of a profiled fragment, click one of the listed attribute values. A form control pops up and allows you to add or remove attribute values.

Figure 830. Profiling Attribute Value Form Control Pop Up



Profiling Attribute Icons in the DITA Maps Manager

The following icons are used to mark profiled and non-profiled topics in the **DITA Maps Manager**:

- ■ - The topic reference contains profiling attributes.
- □ - The topic reference inherits profiling attributes from an ancestor.
- ◪ - The topic reference contains a profiling attribute and inherits profiling from an ancestor.
- – (hyphen) - The topic reference neither contains nor inherits profiling attributes.

Figure 831. Rendering Profiled Topics in DITA Maps Manager

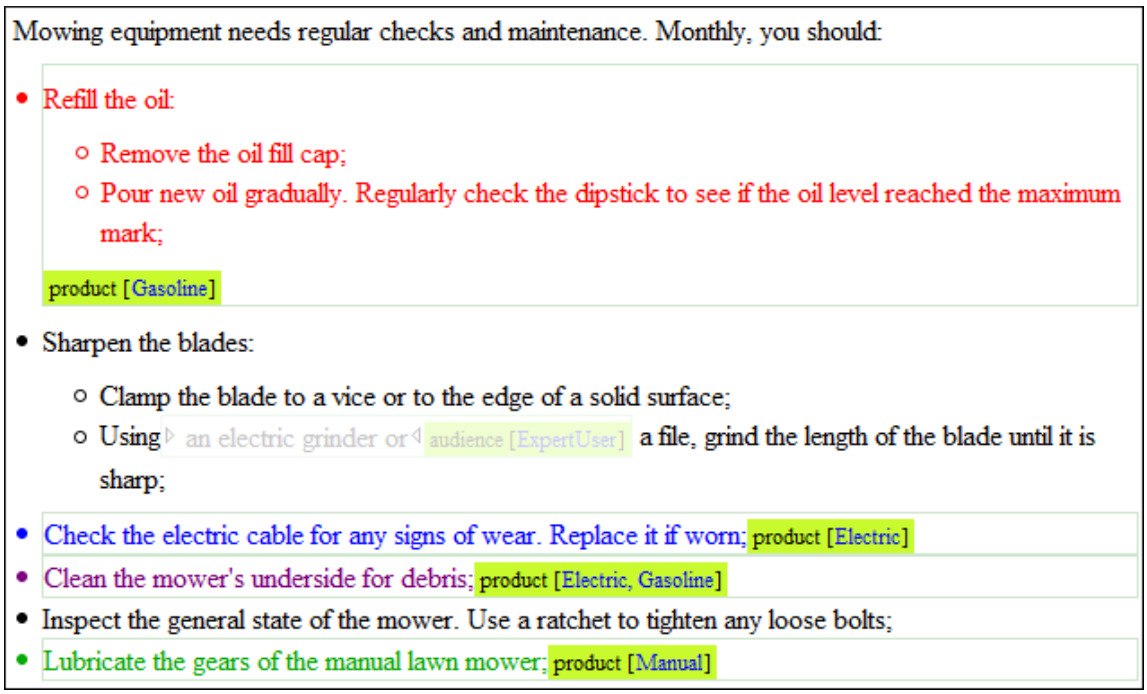
Customizing Colors and Styles for Rendering Profiling in Author Mode *(on page 3333)*

Customizing Colors and Styles for Rendering Profiling in Author Mode

By applying profiling colors and styles, you can mark profiled content in **Author** mode and the **DITA Maps Manager** *(on page 3073)* so that you can instantly spot differences between multiple variants of the output. This allows you to preview the content that will go into the published output. The excluded text is grayed-out or hidden in **Author** mode and excluded nodes are grayed-out or hidden in the **DITA Maps Manager** *(on page 3073)*.

Figure 832. Example: Profiling Colors and Styles in Author Mode



Choosing the right style for a specific profiling attribute is a matter of personal taste, but be aware of the following:

- If the same block of text is profiled with two or more profiling attributes, their associated styles combine. Depending on the styling, this might result in an excessively styled content that may prove difficult to read or work with.
- It is recommended that you only profile the differences. There is no need to profile common content, since excessive profiling can visually pollute the document.
- A mnemonic associated with a style will help you instantly spot differences in the types of content.

Styling Profiling Attribute Values

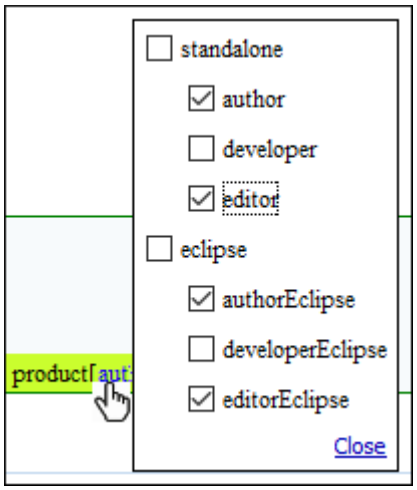
To set colors and styles for profiling attribute values, follow these steps:

1. Select the **Show Profiling Colors and Styles** option *(on page 691)* from the **Profiling / Conditional Text** toolbar drop-down menu.
2. Select **Profiling Settings** *(on page 691)* from the **Profiling / Conditional Text** toolbar drop-down menu. This is a shortcut to the **Attributes and Condition Sets** preferences page *(on page 195)*.
3. Go to the **Colors and Styles** preferences page *(on page 197)* to configure the colors and styling for the profiling attributes.
4. Go to the **Attributes** preferences page *(on page 199)* to configure how you want the profiling attributes to appear in Oxygen XML Editor.

Result: The styling is now applied in the **Author** editing mode, the **Outline** view *(on page 549)*, and in the **DITA Maps Manager** view *(on page 3073)*. Also, to help you more easily identify the profiling you want to apply in

the current context, the styling is applied in the **Edit Profiling Attributes** dialog box *(on page 681)* and in the inline form control pop-up that allows you to quickly set the profiling attributes.

Figure 833. Profiling Attribute Value Form Control Pop Up



Alternate Method with a DITAVAL File: If you are using a DITAVAL filter file to control the filtering of profiled content in DITA topics, you can use a flag filter to define the colors and styles that will be used when rendering the profiling. For detailed information about this alternate method, see the procedure in the Styling the Rendering of Profiled Content Using a DITAVAL File *(on page 3344)* topic.

Conditional Profiling Attribute Groups

Overview

Conditional processing attributes can be specified using grouped values. Groups organize the attributes into subcategories. This is intended to support situations where an attribute applies to multiple specialized subcategories. For example, suppose a company needs to filter content for several internal teams (*operations* and *support*) and they use the `@audience` attribute with the values `ops` and `support`, but the Support team has several levels of personnel (L1, L2, and L3). They could use a group to define the levels (*L1*, *L2*, and *L3*) as subcategories for the `support` value. Using groups for these subcategories allows each category to be processed independently.

A major advantage is that you do not need to add new profiling attributes using a DTD specialization. You can re-use existing DITA profiling attributes (such as `@product`, `@audience`, `@otherprops`) and specify multiple attribute subcategories.

Creating a Conditional Profiling Attribute Group

To create a group in Oxygen XML Editor:

1. Open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to **Editor > Edit modes > Author > Profiling / Conditional Text > Attributes and Condition sets**.
2. To add new attributes and values, click the **New** button at the bottom of the **Profiling Attributes** table. To customize existing attributes and their values, select an attribute and click the **Edit** button.

   Step Result: In either case, this opens a **Profiling Attribute** configuration dialog box where you can define attributes that exist in your schema.
3. Specify the appropriate values for the **Document type**, **Attribute name**, and **Display name**.

   For information about the **Profiling Attribute** configuration dialog box, see Defining Profiling Attributes for DITA Content *(on page 3320)*.
4. Click the **New** button at the bottom of the attribute values table.
5. In the **Value** field of the resulting dialog box, define groups using the following format: `ParentAttrValue(SubAttrValue1 SubAttrValue2)`. For example:

   ```
   support(L1 L2 L3)
   ```
6. Click **OK** and **Apply** to save and apply the changes.

Using Conditional Profiling Attribute Groups in Conjunction with a DITAVAL File

You can use groups to customize a hierarchy of profiling attribute values and then use it in conjunction with a DITAVAL file to filter or flag *(on page 3342)* the values. For example, suppose the company described in the example in the Overview section *(on page 3335)* needed to generate content for the Support team, but only for L1 and L2 support personnel. The DITAVAL file could look like this:

```
<val>
     <prop action="include" att="support" val="L1"/>
     <prop action="include" att="support" val="L2"/>
     <prop action="exclude" att="support" val="L3"/>
</val>
```

That DITAVAL file could then be used for a condition set *(on page 3326)* to filter content in **Author** mode or during the transformation stage to filter content in the output *(on page 3345)* and content profiled with the `L1` and `L2` values would be included while content with the `L3` value would be excluded.

This example company could also have another DITAVAL file for filtering out all content profiled for any of the three subcategories (`L1`, `L2`, `L3`) by simply excluding the `support` value (since `L1`, `L2`, and `L3` are subcategories of it).

```
<val>
     <prop action="exclude" att="support"/>
</val>
```

Defining Conditional Profiling Attribute Groups in a Subject Scheme Map

You can define conditional profiling attribute groups in a subject scheme map *(on page 3337)* as in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE subjectScheme PUBLIC "-//OASIS//DTD DITA Subject Scheme Map//EN" "subjectScheme.dtd">
  <subjectScheme>
    <enumerationdef>
        <attributedef name="product"/>
        <subjectdef keys="productKeys">
            <subjectdef keys="myGroup1(gr1v1)"/>
            <subjectdef keys="myGroup1(gr1v2)"/>
            <subjectdef keys="product1"/>
        </subjectdef>
    </enumerationdef>
  </subjectScheme>
```

In the above example, **myGroup1** is the profiling attribute group for the `@product` attribute and **gr1v1** and **gr1v2** in parentheses are the values.

DITA 1.3 Specifications: Conditional Processing Values and Groups

Customizing Profiling Values with a Subject Scheme Map

Overview

A *subject scheme map (on page 3424)* allows you to create and manage custom profiling values in DITA documents without having to write a DITA specialization. Ultimately, this allows you to filter and flag content in **Author** mode or in transformed output.

Subject scheme maps use key definitions to define a collection of profiling values. You can also use *subject scheme maps* to filter out (reject) the values for certain attributes so that you only see the attributes or values that you want to use in **Author** mode or the transformed output.

The highest level of map (*main DITA map (on page 3424)*) that uses the set of profiling values must reference the *subject scheme map* where the profiling values are defined and the `@type` attribute needs to be set to `subjectScheme` for the reference, as in the following example:

```
<topicref href="test.ditamap" format="ditamap" type="subjectScheme"/>
```

Advantages of Using a Subject Scheme Map

The advantages of using a subject scheme to control profiling attribute values include:

- You can create a hierarchy of profiling attribute values and use a DITAVAL file to filter or flag the tree of values.
- You can share the subject scheme files with others without having to share preferences or the entire project.
- The subject scheme offers validation support so you are notified if an undefined value is used.

Creating a Subject Scheme Map

To create and configure a *subject scheme map*, follow this procedure:

1. Use the **New Document** wizard *(on page 377)* to create a new **Subject Scheme** document (**Framework templates > DITA Map > map >**  **Subject Scheme**).
2. Use the controls in **Author** mode to define the hierarchical tree of values for your *subject scheme* (see the Author mode example below *(on page 3340)*) or switch to **Text** mode and define it there if you prefer (see the Text mode example below *(on page 3340)*).

   Note:
   The pre-defined subject scheme template includes Navigation Titles (`<navtitle>` element). This element is not required, but if you use it, the text that you enter for the `<navtitle>` will be used (instead of the name of the value) in the various places where profiling attributes are presented in Oxygen XML Editor *(on page 3341)*. An example of when this might be helpful is if you want to use abbreviations for the name of a value, but you want to see its full name in Oxygen XML Editor.

3. Bind the particular attribute to the key you define for the tree of values using the `<attributedef>` and `<subjectdef>` elements inside the `<enumerationdef>` element. Notice that in the examples below *(on page 3340)*, the *audience* attribute is bound to the *audienceKey* value.

   Tip:
   By default, attributes can accept multiple values, but you can use `outputclass="single_value"` to specify that a certain attribute only accepts a single value at a time and the attribute will be presented in Oxygen XML Editor with radio buttons instead of checkboxes. For example:

   ```
   <enumerationdef outputclass="single_value">
     <attributedef name="audience"/>
   ```

```
    <subjectdef keyref="audienceKey"/>
  </enumerationdef>
```

You can also define a specific set of possible attribute values for a specific attribute name that is set on a specific element name. For example, you can define a specific set of `@outputclass` attribute values only for the `<image>` element:

```
<enumerationdef>
    <elementdef name="image"/>
    <attributedef name="outputclass"/>
    <subjectdef keyref="imgOutputClassValuesKey"/>
  </enumerationdef>
```

4. If you want to filter out (reject) values for certain attributes, bind the attributes to a blank value (as you see for the `props` and `otherprops` attributes in the examples below *(on page 3340)*). This means that those attributes will not appear in the various places where profiling attributes are presented in Oxygen XML Editor *(on page 3341)*.
5. Save your *subject scheme* file.
6. Reference your *subject scheme* in the highest level of map (*main DITA map (on page 3424)*) that will use the set of profiling values and set its type to `subjectScheme`. The easiest way to do this is:
    a. With your *subject scheme* file opened in the editor, go to the **DITA Maps Manager** view, right-click the *main DITA map*, and select **Append Child > Reference to the currently edited file**.
    b. In the **Insert Topic Reference** dialog box, go to the **Attributes** tab and in the **Type** field, enter or select **subjectScheme**.
    c. Click the **Insert and Close** button and save your main DITA map.

Using a Subject Scheme in Conjunction with a DITAVAL File

You can use a subject scheme to customize a hierarchy of profiling attribute values and then use it in conjunction with a DITAVAL file to filter or flag *(on page 3342)* the entire tree of values. For example, suppose one of the values for the `audience` attribute in a hierarchical subject scheme is `surgeon` and it has two subordinate values of `neuro-surgeon` and `plastic-surgeon` (see the examples below *(on page 3340)*). You could create a DITAVAL file with the following content:

```
<val>
    <prop action="exclude" att="audience" val="surgeon"/>
</val>
```

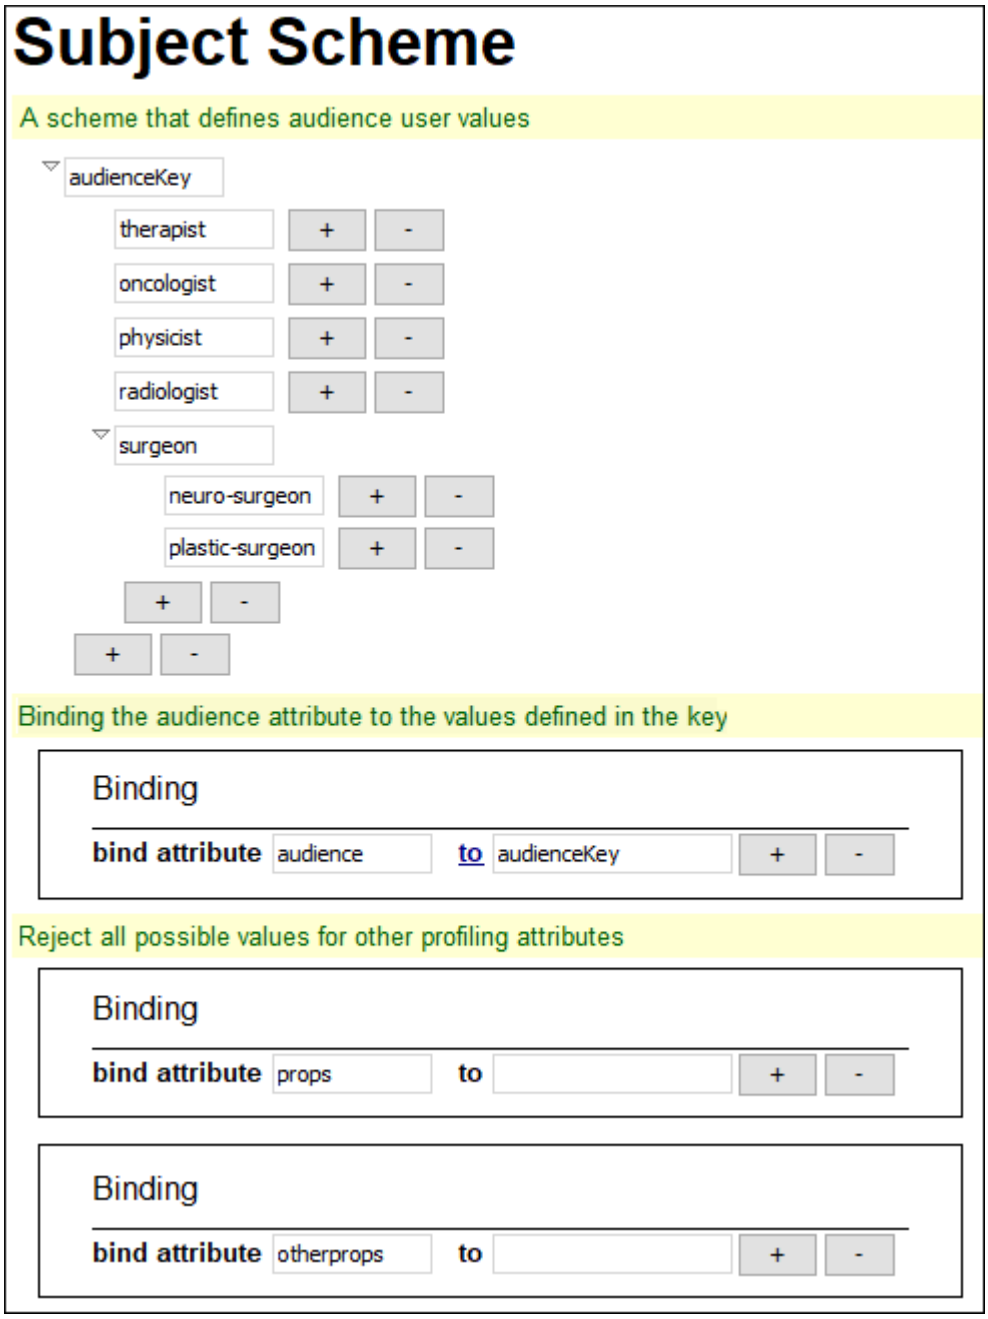
That DITAVAL file could then be used for a condition set *(on page 3326)* to filter content in **Author** mode or during the transformation stage to filter content in the output *(on page 3345)* and the `neuro-surgeon` and `plastic-surgeon` values would be excluded by the filter since the subject scheme defines them as subordinate values of the `surgeon` value.

Example: Subject Scheme Map that Defines Custom Values for the Audience Attribute

This example uses typical audience values for medical personnel (`therapist`, `oncologist`, `physicist`, `radiologist`, `surgeon`, and so on). The `audience` attribute is bound to the `audienceKey` value (which defines the tree of values). You can also see that it filters out all possible values for other attributes (`props` and `otherprops`) so that they won't be available in the various places where profiling attributes are presented in Oxygen XML Editor *(on page 3341)*.

Example using Author mode controls:

Figure 834. Subject Scheme Author Mode Controls



Example code in Text mode:

```
<subjectScheme>
  <!-- A scheme that defines audience user values -->
  <subjectdef keys="audienceKey">
    <subjectdef keys="therapist"/>
    <subjectdef keys="oncologist"/>
    <subjectdef keys="physicist"/>
    <subjectdef keys="radiologist"/>
    <subjectdef keys="surgeon">
      <subjectdef keys="neuro-surgeon"/>
      <subjectdef keys="plastic-surgeon"/>
    </subjectdef>
  </subjectdef>
  <!-- Binding the audience attribute to the values defined in the key -->
  <enumerationdef>
    <attributedef name="audience"/>
    <subjectdef keyref="audienceKey"/>
  </enumerationdef>

  <!--Reject all possible values for other profiling attributes-->
  <enumerationdef>
    <attributedef name="props"/>
    <subjectdef/>
  </enumerationdef>
  <enumerationdef>
    <attributedef name="otherprops"/>
    <subjectdef/>
  </enumerationdef>
</subjectScheme>
```

Where the Profiling Attributes are Available in Oxygen XML Editor

When you edit a DITA topic in the **Text** or **Author** mode, Oxygen XML Editor collects all the profiling values from the *subject scheme map (on page 3424)* that is referenced in the map that is currently opened in the **DITA Maps Manager** *(on page 3073)* (or set as the *root map (on page 3090)*). The values of profiling attributes defined in a *Subject Scheme Map* are available in the following places in Oxygen XML Editor (regardless of their mapping in the **Profiling/Conditional Text** preferences page *(on page 195)*):

- The **Profiling** tab of the **Edit Properties** dialog box *(on page 3114)*.
- The **Edit Profiling Attribute** dialog box *(on page 3324)*.
- The inline profiling controls in **Author** mode *(on page 3331)*.
- The proposals for the attribute values in the *Content Completion Assistant (on page 3418)*.

Related Information:

Filtering Profiling Values with a DITAVAL File *(on page 3342)*

DITA 1.3 Specifications: Subject Scheme Maps

Filtering Profiling Values with a DITAVAL File

You can use a DITAVAL filter file to control the filtering or flagging of profiled content or to identify which values are to be used for conditional processing during a particular output.

DITAVAL Filtering Use-Case

Suppose that a medical publication uses the *audience* profiling attribute to profile the content for the following types of users: *therapist*, *physician*, and *surgeon*. Suppose that in the output, you want to exclude any content that is profiled as `surgeon` value for the `@audience` attribute.

You could use a DITAVAL filter file to exclude anything that is profiled as `surgeon`:

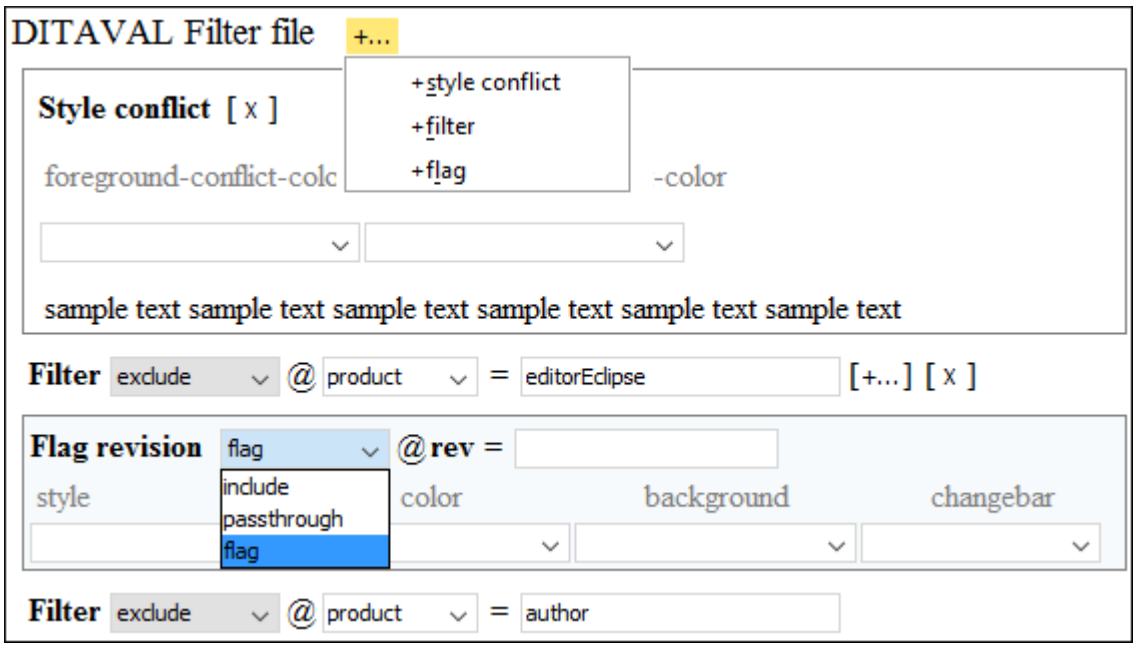
```
<val>
    <prop action="exclude" att="audience" val="surgeon"/>
</val>
```

If you then transform the main *DITA map (on page 3419)* and specify the DITAVAL filter file in the transformation scenario, the output will exclude anything that is profiled as `surgeon`).

DITAVAL Filter File Editor in Author Mode

The **Author** editing mode in Oxygen XML Editor offer a simple and intuitive editor for creating or modifying DITAVAL files. It provides a series of drop-down menus and text fields that allow you to easily define the filters.

Figure 835. DITAVAL File Editor in Author Mode



Use the **+...** button to display a drop-down list that contains elements that you can add at that particular location in the DITAVAL file. Clicking this button at the top (next to the **DITAVAL FILTER File** title, allows you to insert the following elements:

- **Style Conflict** - Inserts a `<style-conflict>` element that declares behavior to be used when one or more flagging methods collide on a single content element. You can use the simple drop-down menus to select values for the `@foreground-conflict-color` and `@background-conflict-color` attributes.
- **Filter** - Inserts a `<prop>` element that identifies an attribute to apply a filtering action on. The possible actions that you can select are **include**, **exclude**, **passthrough**, and **flag**. If you select the **flag** action, you can use the drop-down menus to select values for the `@style`, `@color`, and `@background` attributes.
- **Flag** - Inserts a `<revprop>` element that Identifies a value in the `@rev` attribute that should be flagged in some manner. The allowed actions are **include**, **passthrough**, and **flag**. If you select the **flag** action, you can use the drop-down menus to select values for the `@style`, `@color`, `@background`, and `@changebar` attributes.

See the DITAVAL Element Specifications for more details about the allowed filters and flags.

How to Create a DITAVAL Filter File

To create a DITAVAL filter file, follow these steps:

1. Go to **File > New**.
2. Scroll to the **Framework templates > DITA** folder.
3. Select the **Filter** template file and click **Create**.
4. Define your filters in the DITAVAL file (in **Text** or **Author** mode).
5. Save the DITAVAL file.

Result: The DITAVAL filter file can now be used for all of the following:

- To apply a reference to the DITAVAL file in a *Profiling Condition Set* using the **Use DITAVAL File** option in the **Condition Set** configuration dialog box *(on page 3326)*.
- You can use the **Import from DITAVAL** option in the **Attributes and Condition Sets** preferences page *(on page 195)* to use the DITAVAL file to define profiling attributes.
- You can use the DITAVAL file to apply the filters to the output by specifying the DITAVAL file in the transformation scenario *(on page 3299)*.
- You can use the filter file in the **DITA Map Completeness Check** dialog box *(on page 3119)* when validating your *DITA map (on page 3419)*.
- DITAVAL files are also used when working with the DITA 1.3 *Branch Filtering* mechanism. For more details, see: Working with DITA 1.3 Branch Filtering *(on page 3241)*.
- You can define the colors and styles to be used for rendering profiled condition sets *(on page 3344)* in **Author** mode and the **DITA Maps Manager** *(on page 3073)* view by using a **Flag** filter in the DITAVAL file.

Styling the Rendering of Profiled Content Using a DITAVAL File

If you are using a DITAVAL filter file to control the filtering of profiled content, you can define the colors and styles to be used for rendering profiled condition sets in **Author** mode and the **DITA Maps Manager** *(on page 3073)* by defining the styles in a flag filter that is set in a DITAVAL filter file.

How to Define a Flag for a Condition Set in a DITAVAL Filter File

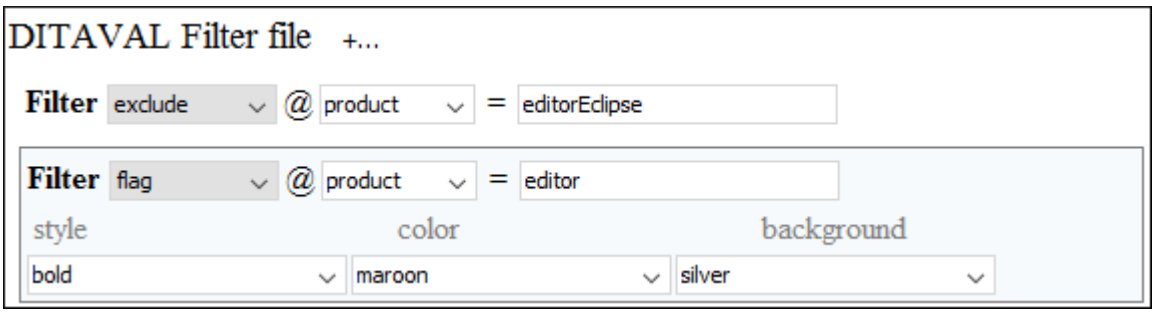
To define the colors and styles to be used for rendering profiled condition sets by using a flag filter in a DITAVAL filter file, follow these steps:

1. Create or edit your DITAVAL file *(on page 3343)* to define your profiling condition set *(on page 3326)*.
2. In **Author** mode, define the filters for your condition set *(on page 3342)*.
3. Select **Flag** from the drop-down menu on in a particular **Filter** or **Flag Revision** to present additional drop-down menus that allow you to configure the colors and styles for the particular condition set.
4. Save the DITAVAL file.

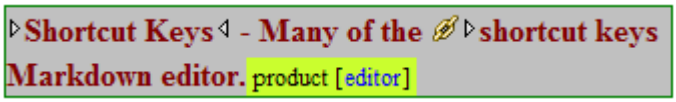
Result: Test your changes by opening profiled content in **Author** mode or the **DITA Maps Manager** *(on page 3073)* and use the options in the **Profiling / Conditional Text** drop-down menu to see how the changes in your DITAVAL flag are rendered.

EXAMPLE:

Using a **Flag** on a **Filter** to define the styling for a condition set like this:



will render the styling of the profiled content in **Author** mode to look like this:



and will render the styling in the **DITA Maps Manager** view *(on page 3073)* to look like this:

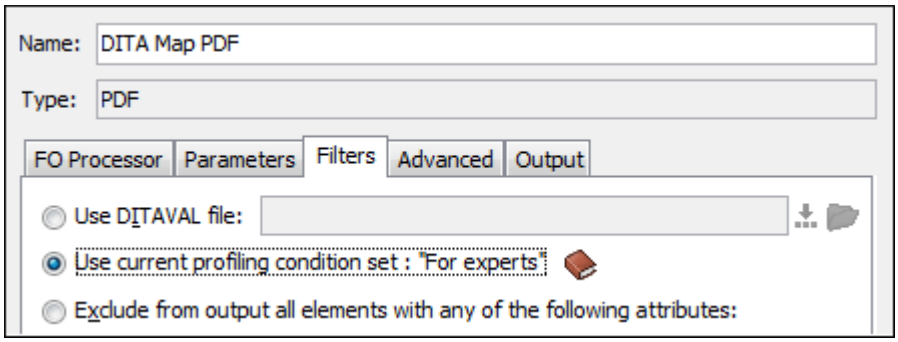
Filtering Profiling Values with a DITAVAL File *(on page 3342)*

Publishing Profiled DITA Content

You can create a variety of publications or versions of your documentation from a single map by applying profiling conditions to the build.

Oxygen XML Editor includes preconfigured transformation scenarios for DITA. By default, these scenarios take the current profiling condition set *(on page 3328)* into account during the transformation, as defined in the **Filters** tab *(on page 3299)* when creating a DITA transformation *(on page 1530)*. You can also specify a DITAVAL file *(on page 3342)* that defines filters for your profiled content.

Figure 836. Profiling Option in the Filters Tab (DITA-OT Transformations)



Conditional Processing to Generate Multiple Deliverables

By default, the content of most elements is included in all output media. Within maps and topics, elements can specify the delivery targets to which they apply.

Within maps, topic references can use the `@deliveryTarget` attribute to indicate the delivery targets to which they apply. Within topics, most elements can use the `@deliveryTarget` attribute to indicate the delivery targets.

If a referenced topic should be excluded from all output formats, set the `@processing-role` attribute to **resource-only** instead of using the `@deliveryTarget` attribute. Content within that topic can still be referenced for display in other locations.

`@deliveryTarget`

The intended delivery target of the content, for example **html**, **pdf**, or **epub**. This attribute is a replacement for the now deprecated `@print` attribute.

The `@deliveryTarget` attribute is specialized from the `@props` attribute. It is defined in the *deliveryTargetAttDomain*, which is integrated into all OASIS-provided document-type shells. If this domain is not integrated into a given document-type shell, the `@deliveryTarget` attribute will not be available.

The `@deliveryTarget` attribute is processed the same way as any other conditional processing attribute. For example, `<topicref deliveryTarget="html5 epub" href="example.dita"/>` uses two values for `@deliveryTarget`. A conditional processing profile can then set rules for `@deliveryTarget` that determine whether the topic is included or excluded when the map is rendered as HTML5 or EPUB.

DITA Open Toolkit Support

The *DITA Open Toolkit* is an open-source publishing engine that can generate various output formats (for example, HTML, PDF, CHM) from DITA content. Oxygen XML Editor includes support for the DITA Open Toolkit. This section includes information about how to install and create a DITA-OT *plugin (on page 3422)*, and how to use an external instance of the DITA Open Toolkit.

Related Information:
DITA Open Toolkit Documentation

DITA-OT Plugins

The architecture of the DITA Open Toolkit publishing engine is plugin-based. A plugin can add support for publishing DITA content as a new format or for customizing an existing output format. The DITA Open Toolkit bundled with Oxygen XML Editor already has lots of plugins pre-installed but you can also install additional *plugins (on page 3422)* or create your own.

Creating a DITA-OT Plugin

Oxygen XML Editor provides the ability to install additional **DITA Open Toolkit** *plugins (on page 3351)* that can be found from various sources (for example, *Oxygen's* public GitHub repository includes some DITA-OT plugins). It is also possible to create your own *plugin*.

CAUTION:
Oxygen XML Editor support engineers do not officially offer support and troubleshooting assistance for custom DITA-OT distributions or custom installed DITA-OT plugins. If you discover any issues or inconsistent behavior while using a custom DITA-OT or a DITA-OT that contains custom DITA-OT plugins, you should revert to the default built-in DITA-OT.

To create a DITA-OT *plugin*, follow these steps:

1. Create a new folder in the **plugins** folder located in your DITA-OT directory (for example, if you are using DITA 4.1.2, the path would look like this: *`[OXYGEN_INSTALL_DIR]`*`/frameworks/dita/`*`DITA-OT`*`/plugins/MyNewPlugin`).
2. Create a **plugin.xml** file in that same folder. This file will contain the extension points for the *plugin*. For example, references to the XSLT stylesheets that will be used to style the output.

   Note:
   You can easily create this file by using the **DITA-OT Plugin** new document template that is included in Oxygen XML Editor (from the **New** document wizard *(on page 377)* you can find this template in **Framework templates > DITA > plugin**.

   Example:

   ```
   <plugin id="org.metadita.specialization.music">
     <feature extension="dita.specialization.catalog.relative"
              file="catalog-dita.xml"/>
     <feature extension="dita.xsl.xhtml" file="xsl/music2xhtml.xsl"/>
     <feature extension="dita.xsl.html5" file="xsl/music2xhtml.xsl"/>
   </plugin>
   ```

   Tip:
   Oxygen XML Editor includes special editing support when adding extension points in the **plugin.xml** file. If you place the cursor in the value of the `@extension` attribute and press **Ctrl+Space**, a list of possible extension points is presented with links to the DITA-OT documentation. For more information about extension points that are available to use in the *plugin.xml* file, see: http://www.dita-ot.org/dev/extension-points/extension-points-by-plugin.html.

3. Install the newly created DITA-OT *plugin (on page 3351)* by running the built-in transformation scenario called **Integrate/Install DITA-OT Plugins** *(on page 3287)* from the **Apply Transformation Scenario(s)** *(on page 1471)* or **Configure Transformation Scenario(s)** dialog box *(on page 1600)*.

   > **Note:**
   > If the *integrator* is not visible, select the **Show all scenarios** option in the **Settings** drop-down menu.

You can share your new plugin with other users who have the same DITA-OT distribution by sending them your newly created folder along with the installation instructions *(on page 3351)*.

Related Information:
DITA Open Toolkit Documentation
Defining the Transformation Type and Allowed Parameters in a DITA-OT Plugin *(on page 3352)*

Example: Creating a DITA-OT Plugin for Embedding Video Resources

To offer a detailed example of the steps required to create a new **DITA Open Toolkit** *plugin (on page 3422)*, this topic uses an example of creating an **XSLT** customization *plugin* that provides support for referencing video and audio content using the DITA `<object>` element and then publishing to **HTML** and **PDF** output formats. This *plugin* (**com.oxygenxml.media**) is available in the **DITA Open Toolkit** distribution that comes bundled with the latest version of Oxygen XML Editor, but these instructions show you how you could create it if it were not included.

The following procedure is meant to help you with creating the *plugin*:

1. Create a folder for your *plugin* in the DITA-OT **plugins** folder (*DITA-OT-DIR*`/plugins/`).
2. Create a **plugin.xml** file (in the same *plugin* folder) that contains the extension points of the *plugin*.

   > **Note:**
   > You can easily create this file by using the **DITA-OT Plugin** template that is included in Oxygen XML Editor (from the **New** document wizard *(on page 377)* you can find this template in **Framework templates > DITA > plugin**).

   Example: Media Plugin File

```
<plugin id="com.oxygenxml.media">
  <feature extension="package.support.name" value="Oxygen XML Editor Support"/>
  <feature extension="package.support.email" value="support@oxygenxml.com"/>
  <feature extension="package.version" value="21.0"/>
  <feature extension="dita.xsl.xhtml" value="xhtmlMedia.xsl" type="file"/>
  <feature extension="dita.xsl.xslfo" value="pdfMedia.xsl" type="file"/>
</plugin>
```

The most important extensions in it are the references to the XSLT stylesheets that will be used to style the HTML and PDF outputs.

You can find other **DITA-OT** *plugin* extension points here: http://www.dita-ot.org/dev/extension-points/extension-points-by-plugin.html.

3. Create an XSLT stylesheet to customize the output types. In this example, to customize the HTML output, it is necessary to create an XSLT stylesheet called **xhtmlMedia.xsl** (in the same *plugin* folder).

   > **Tip:**
   > You can use the **Find/Replace in Files** action *(on page 446)* to find an XSLT stylesheet with content that is similar to the desired output and use it as a template to overwrite parts of your stylesheet. For example, suppose you want to overwrite HTML content produced from a DITA **codeblock** element. Since a DITA `<object>` element has the `@class` attribute value `- topic/object` , you can take part of the class attribute value (**topic/object**) and search the **DITA-OT** resources for a similar stylesheet. The search might find the XSLT stylesheet *DITA-OT-DIR*`/plugins/org.dita.xhtml/xsl/xslhtml/xsl/xslhtml/dita2htmlImpl.xsl`.

   You can use it as a starting point to overwrite the **xhtmlMedia.xsl** stylesheet. For example, the results might be:

   ```
   <xsl:template
      match="*[contains(@class, ' topic/object ')][contains(@outputclass, 'video')]">
    <video class="embed-responsive-item">
      <xsl:call-template name="commonattributes"/>
      <xsl:call-template name="setidaname"/>
      <xsl:call-template name="copySource"/>
    </video>
   </xsl:template>
   ```

4. Create additional XSLT stylesheets to customize all other desired output types. In this example, to customize the PDF output it is necessary to create an XSLT stylesheet called **pdfMedia.xsl** (in the same *plugin* folder).

   In this case, you might find an appropriate XSLT stylesheet called *DITA-OT-DIR*`/plugins/org.dita.pdf2/xsl/fo/topic.xsl` to use as a starting point to overwrite the **pdfMedia.xsl** stylesheet, with results looking something like this:

   ```
   <!--Treat video, audio or iframe objects as links-->
   <xsl:template
              match="*[contains(@class,' topic/object ')][@outputclass = 'video']">
       <xsl:variable name="target" select="@data"/>
       <xsl:variable name="baseDir">
         <xsl:call-template name="substring-before-last">
          <xsl:with-param name="text" select="@xtrf"/>
   ```

```
      <xsl:with-param name="delim" select="'/'"/>
     </xsl:call-template>
    </xsl:variable>

    <fo:inline xsl:use-attribute-sets="object">
      <xsl:call-template name="commonattributes"/>
      <xsl:if test="exists($target)">
        <fo:basic-link external-destination="url({$target})"
                                    xsl:use-attribute-sets="xref">
          <xsl:value-of select="$target"/>
        </fo:basic-link>
      </xsl:if>
    </fo:inline>
</xsl:template>
```

5. To install the created *plugin* in the **DITA-OT**, run the built-in transformation scenario called **Integrate/Install DITA-OT Plugins** *(on page 3287)* by executing it from the **Apply Transformation Scenario(s)** dialog box *(on page 1471)*. If the integrator is not visible, select the **Show all scenarios** option that is available in the **Settings** drop-down menu. For more information, see Installing a DITA-OT Plugin *(on page 3351)*.

   Results of running the integrator using the media plugin example:

   XSLT content is applied with priority when publishing to both HTML and PDF outputs.

   a. For the HTML output, in the XSLT stylesheet *DITA-OT-DIR*`/plugins/org.dita.xhtml/xsl/dita2html-base.xsl`, a new import automatically appeared:

      ```
      <xsl:import href="../plugins/com.oxygenxml.media/xhtmlMedia.xsl"/>
      ```

      This import is placed after all base imports and thus has a higher priority. For more information about imported template precedence, see: http://www.w3.org/TR/xslt#import.

   b. Likewise, for the PDF output, in the top-level stylesheet *DITA-OT-DIR*`/plugins/org.dita.pdf2/xsl/fo/topic2fo_shell_fop.xsl`, a new import statement appeared:

      ```
      <xsl:import href="../../../com.oxygenxml.media/pdfMedia.xsl"/>
      ```

Now, you can distribute your *plugin* folder to anyone that has a DITA-OT installation along with some simple installation notes. Your customization will work provided the templates you are overwriting have not changed from one DITA-OT distribution to the other.

DITA Open Toolkit Documentation

Installing a DITA-OT Plugin

Oxygen XML Editor comes bundled with various DITA-OT *plugins (on page 3422)*, but the architecture of the **DITA Open Toolkit** also allows you to install additional *plugins* that can be found from various sources (for example, *Oxygen's* public GitHub repository includes some DITA-OT plugins).

CAUTION:
Oxygen XML Editor support engineers do not officially offer support and troubleshooting assistance for custom DITA-OT distributions or custom installed DITA-OT plugins. If you discover any issues or inconsistent behavior while using a custom DITA-OT or a DITA-OT that contains custom DITA-OT plugins, you should revert to the default built-in DITA-OT.

Installing a DITA-OT Plugin

To install a DITA-OT plugin, following this procedure:

1. Copy the additional *plugin* to the location of the DITA-OT version you are using (by default, `DITA-OT-DIR\plugins` directory).
2. Select the  **Configure Transformation Scenario(s)** *(on page 1600)* action from the **DITA Maps Manager** toolbar (you could also use the same action on the main toolbar or open the **Transformation Scenarios** view *(on page 1607)*).
3. Select the **Integrate/Install DITA-OT Plugins** transformation scenario *(on page 3287)*. If the *integrator* is not visible, select the **Show all scenarios** option that is available in the  **Settings** drop-down menu.

   Important:
   The folder where the **DITA-OT** is located needs to have full write access permissions set to it. For example, in **Windows**, if you are integrating *plugins* in the **DITA-OT** folder bundled with Oxygen XML Editor and your application is installed in the **Program Files** folder, you can start the Oxygen XML Editor main executable with administrative rights for the integrator process to be able to modify resources in the **DITA-OT** folder.

4. Apply the scenario *(on page 1600)*.
5. Check the **Results** panel at the bottom of the application to make sure the build was successful.

After the installation, you can open a DITA map and use the **Configure Transformation Scenarios** dialog box to create a new **DITA-OT** transformation scenario. Oxygen XML Editor detects that transformation type declaration from the **DITA-OT** *plugin* and presents descriptions in the **DITA Transformation Type** dialog box *(on page 1530)*. Oxygen XML Editor also shows the contributed parameters from the plugin in the transformation scenario's **Parameters** tab *(on page 3297)*.

Tip:
You can declare the transformation type and allowed parameters by following the procedure found in: Defining the Transformation Type and Allowed Parameters in a DITA-OT Plugin *(on page 3352)*.

Related Information:
Creating a DITA-OT Plugin *(on page 3347)*
Installing the DITA For Publishers Package
DITA Open Toolkit Documentation
Defining the Transformation Type and Allowed Parameters in a DITA-OT Plugin *(on page 3352)*

Defining the Transformation Type and Allowed Parameters in a DITA-OT Plugin

Custom **DITA-OT** *plugins* may contribute new transformation types (transtypes) and each transtype may have a set of allowed configuration parameters. If a DITA-OT plugin declares a **transtype**, Oxygen XML Editor detects that transformation type declaration and presents descriptions in the **DITA Transformation Type** dialog box *(on page 1530)* and the contributed parameters in the transformation scenario's **Parameters** tab *(on page 3297)*.

To define a transformation type and its contributed parameters in a DITA-OT plugin, follow this procedure:

1. If you have not already done so, create a DITA-OT **plugin.xml** file *(on page 3347)* (you can easily create this file by using the **DITA-OT Plugin** new document template in the **New** document wizard *(on page 377)*).
2. In the **plugin.xml** file, define the transformation type details by using the `<transtype>` element to specify a name, description, and the transtype it extends.

   ```
   <transtype name="xhtml" extends="base-html" desc="HTML">
   ```

3. Define allowed parameters by using the `<param>` element to specify the name, description, and information about the default and allowed set of values. For more information, see: https://www.dita-ot.org/3.1/topics/plugin-configfile.html.

   ```
   <param name="args.indexshow" desc="Specifies whether to show the index" type="enum">
     <val>yes</val>
     <val default="true">no</val>
   </param>
   ```

   Depending on the type declared for a parameter, Oxygen XML Editor will help you pick values for each parameter edited in the **Parameters** tab of the transformation scenario configuration dialog box. For example, for parameters of type "**enum**", Oxygen XML Editor will present a combo box for choosing the proper value for the parameter.
4. You can also extend various extension points in your **plugin.xml**. For more information, see: https://www.dita-ot.org/3.1/extension-points/plugin-extension-points.html.

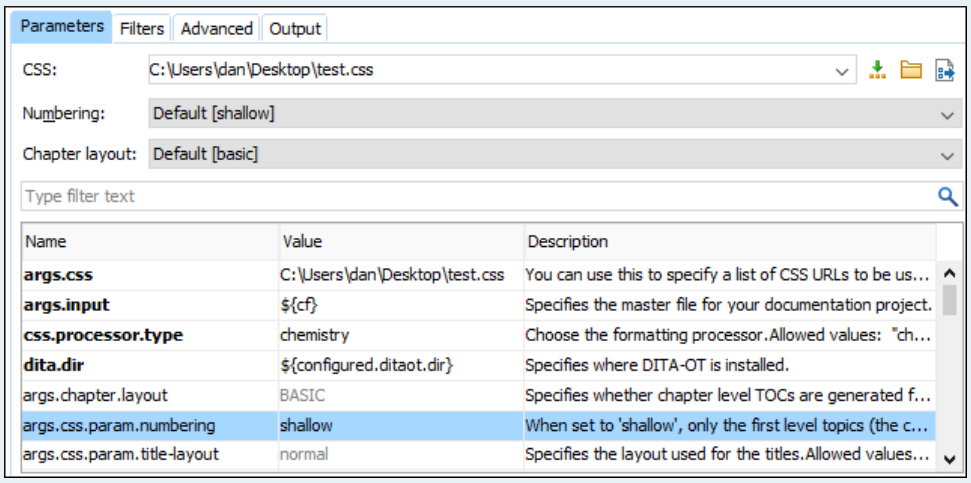
Plugin Extension Example - Promote Parameters:

It is possible to promote certain transformation parameters so that they appear above the table of allowed parameters and values in the **Parameters** tab of the transformation scenario configuration dialog box. To do this, you could create a `pluginExtension.xml` file in the root folder of the DITA-OT plugin and use the `<promotedParams>` element to define the promoted parameters. Here is an example:

```
<extensionPlugin>
    <transtype name="pdf-css-html5">
        <promotedParams>
            <param name="args.css" promotedName="CSS"/>
            <param name="args.css.param.numbering" promotedName="Numbering"/>
            <param name="args.chapter.layout" promotedName="Chapter layout"/>
        </promotedParams>
    </transtype>
</extensionPlugin>
```

The example above results in the **Parameters** tab looking like this:

Figure 837. Promoted Parameters



5. Install the plugin *(on page 3351)*.

Note:
If the plugin is installed using an external command line, you may need to restart Oxygen XML Editor to properly re-detect the newly contributed transtypes and parameters.

Example of a *plugin.xml* File:

```
<plugin id="com.oxygenxml.pdf.prince">
  <!-- extensions -->
```

```
  <feature extension="dita.conductor.transtype.check" value="pdf-prince" type="txt"/>
  <feature extension="dita.conductor.target.relative" value="integrator.xml"
    type="file"/>
  <feature extension="dita.transtype.print" value="pdf-prince"/>
  <transtype name="pdf-prince" extends="commons" desc="PDF (Prince XML)">
    <param name="princeExecPath" type="file" desc="Path to the Prince executable"/>
  </transtype>
</plugin>
```

https://www.youtube.com/embed/LcrR0YUFlQ4

Built-in Third-Party DITA Open Toolkit Plugins

The DITA Open Toolkit 4.1.2 distribution that is bundled with Oxygen XML Editor includes some pre-installed third-party open-source *plugins* *(on page 3422)* that add extra publishing formats and functionality.

The *plugins* that come bundled with Oxygen XML Editor include:

- **DITA For Publishers** - These *plugins* allow DITA content to be published to additional formats, such as EPUB 2.0 and Kindle.
- **DITA to Word** - This *plugin* allows users to publish DITA content to MS Word.
- **DITA Community** - These *plugins* allow support for DITA 1.3 with embedded or referenced MathML and SVG images.

Extra Free Publishing Plugins

The DITA Open Toolkit publishing engine comes with support for predefined output formats such as HTM5, PDF, and Eclipse Help. Since the architecture of the publishing engine is plugin-based, over time, lots of useful plugins were developed in the **Oxygen XML GitHub** account that enhance the publishing and some of them are listed below. The plugins that are already installed within the DITA-OT engine that comes bundled with Oxygen XML Editor are listed with a **[Bundled]** marker.

Plugin that Converts DITA Maps to PDF Using CSS 3 [Bundled]

You can use this very popular plugin to publish DITA to PDF output using CSS. As the publishing engine, it can use the **Oxygen XML Chemistry** processor (freely bundled with **Oxygen XML Editor**), the Antenna House engine, or the Prince XML engine.

DITA Metrics Report [Bundled]

This is a very useful open-source plugin can be used to generate an HTML report from an existing DITA project and contains a lot of useful information, including:

- Total number of maps and topics that are part of the project.
- Total number of elements used in topics and maps along with a table presenting all element names and their usage counter.
- The used elements for each DITA domain.
- Total number of attributes used in topics and maps along with a table presenting all attribute names and their usage counter.
- Statistics about the conditional attributes used in the project.
- Information about content reuse.
- Text and content statistics, including both total words (word count) and unique words (vocabulary).
- List of largest and smallest topics and the number of words each one uses.
- Listing of all links to resources outside of the project.
- A metrics evolution report between different versions of your documentation.

Export DITA Map Plugin [Bundled]

You can use this free plugin to create a ZIP file from your entire DITA project. The plugin also takes filters/profiling into account when including topics.

Publish DITA Content with References to Video and Audio Resources. [Bundled]

A DITA Open Toolkit plugin can be used to convert the DITA `<object>` element to various HTML 5 structures (such as <`<video>`, `<audio>`, or `<iframe>`).

Show Consecutive *Codeblocks* in Multiple Tabs for WebHelp Output

This open-source plugin can be used to display consecutive DITA `<codeblock>` elements in separate tabs.

Add Edit Links in HTML or PDF-based Output [Bundled]

This plugin can be used to add edit links in HTML or PDF-based output that allows subject matter experts to offer feedback for the published content directly in the source using a DITA web editing tool (such as **Oxygen XML Web Author**).

Create a Single Merged XML Document From an Entire DITA Project [Bundled]

This plugin can be used to produce a merged output from the entire DITA map structure without further processing. It is useful if you want to further process the merged XML document for producing various reports.

Dynamically Publish Excel Content as DITA

A DITA Open Toolkit plugin that can be used to dynamically convert Excel files to DITA (Excel files referenced with `format="excel"` in DITA maps).

Dynamically Use JSON Content in DITA Topics

A DITA Open Toolkit plugin that can be used to dynamically convert JSON content to DITA (JSON files referenced with `format="json"` in DITA maps).

Dynamically Publish *ASCIIDoc* Content as DITA

A DITA Open Toolkit plugin that can be used to dynamically convert *ASCIIDoc* content to DITA (*ASCIIDoc* files referenced with `format="ant-parser"` in DITA maps).

Embed HTML Content in DITA Topics [Bundled]

A plugin that can be used to embed well-formed HTML content in a DITA topic inside a special element.

Embed *LateX* Equations in DITA Content

A DITA Open Toolkit plugin that can be used to publish embedded *LateX* mathematical equations to HTML and PDF.

Embed UML Diagrams in DITA Content

A DITA Open Toolkit plugin that can be used to publish embedded UML diagrams equations to HTML and PDF.

Float Images in HTML and PDF Outputs

A plugin that can be used to float an image referenced in a DITA topic left or right depending on the specified `@outputclass` attribute value.

Embed Referenced MathML and SVGZ Images in HTML Output

A DITA Open Toolkit plugin that can be used to embed referenced MathML and SVG images in the HTML5 and XHTML output.

Dynamically Convert DITA Tables to Graphs

A DITA Open Toolkit plugin that converts DITA tables having a certain structure to SVG graphs.

Show Oxygen Change Tracking Information in the PDF Output [Bundled]

This plugin can be used to display **Oxygen XML Editor** tracked changes (insertions, deletions, or comments) in the PDF output.

Sample Customization Plugin for Classic PDF (XSL-FO) Output

This sample DITA Open Toolkit PDF customization plugin is a good starting point if you want to:

- Customize fonts.
- Customize a cover page to provide custom logos and coloring.
- Customize page headers and footers.

PDF (XSL-FO) - Generate Numbers Before a Topic's Title

A DITA-OT PDF2 customization plugin that can be installed to generate numbers before each topic's title.

Presents Chapters With Landscape Orientation in PDF (XSL-FO) output

A PDF customization folder that can be used to define landscape orientation for a certain chapter.

Using an External DITA Open Toolkit in Oxygen XML Editor

Oxygen XML Editor comes bundled with a DITA Open Toolkit, located in the *`DITA-OT-DIR`* directory. If you want to use an external DITA-OT for all transformations and validations, you can open the **Preferences** dialog box **(Options > Preferences)** *(on page 131)* and go to the **DITA** page *(on page 277)*, where you can specify the DITA-OT to be used.

Related Information:
Editing a Transformation Scenario *(on page 1597)*
Creating New Transformation Scenarios *(on page 1504)*
DITA Open Toolkit Documentation

DITA Open Toolkit Project

The *DITA Open Toolkit* project file allows you to define all your DITA map input and filter pairs and to produce the desired output formats by applying the publishing engine over this single project file: https://www.dita-ot.org/dev/topics/using-project-files.html.

Oxygen XML Editor has special support for creating, editing, validating, and publishing DITA Open Toolkit project files represented in XML format. It can also use such files to detect connections between DITA resources in the entire project and to apply root map and filter pairs when editing.

Editing DITA Open Toolkit Project Files

The **New Document** wizard *(on page 377)* includes a template to help you create DITA Open Toolkit project files (with an `.xml` file extension). The template is located in the **Framework templates > DITA-OT** folder. There is also a sample project file that can be found in the application samples folder: `OXYGEN_INSTALL_DIR/samples/dita/mobile-phone/mobilePhoneProjectFile.xml`.

When working with a DITA-OT project file in the **Author** visual editing mode, you can see a compact representation of the file by default. You can switch to the **Edit** style in the **Styles** toolbar drop-down menu to edit the file using form controls and inline buttons. The additional **View as YAML** style can be selected to see a visual representation of the same document in YAML. Content for all additional project files included in

the current edited file will appear expanded in place. The included content is read-only by default but can be directly edited if the **Allow referenced content to be edited** checkbox is selected in the **Options > Preferences > Editor > Edit Modes > Author**preferences page.

DITA-OT Project File Content Completion

Content completion is available according to the associated schema and it is enhanced with proposals for ID references, available transformation types, parameter names, and values.

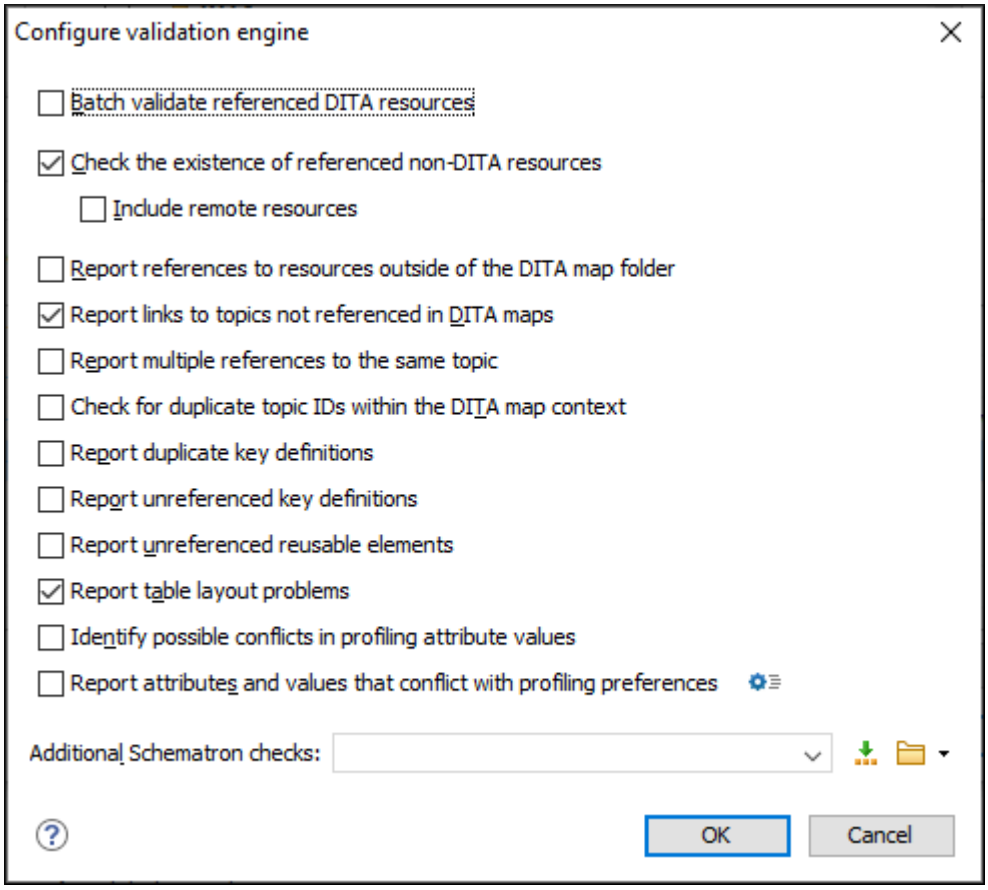
DITA-OT Project File Validation

The default automatic validation support for DITA-OT project files has enhanced Schematron rules that report invalid references to non-existing contexts. The default validation is based on a validation scenario named **DITA-OT Project** that in included in the DITA-OT project framework.

The DITA-OT Project framework also includes a *validation scenario* named **DITA-OT Project Validation and Completeness Check**. It contains validation units that automatically validate the project file based on the **DITA-OT Project** scenario and also a manual validation unit based on the **DITA-OT Project Validation and Completeness Check** *validation engine* that validates all contexts recursively.

When creating a validation scenario *(on page 799)*, or editing an existing scenario *(on page 809)* for a DITA-OT project file, you can select **DITA-OT Project Validation and Completeness Check** engine in the **Validation engine** column and clicking the **Settings** button for that engine opens the **Configure validation engine** dialog box where you can configure options for validating the DITA-OT project.

Figure 838. Configure Validation Engine Dialog Box for DITA-OT Project Validation



The options available in this dialog box include:

Batch validate referenced DITA resources

This option specifies the level of validation that applies to referenced DITA files:

- If the checkbox is left unchecked (default setting), the DITA files will be validated using the rules defined in the DTD or XML Schema declared in the document.
- If the checkbox is selected, the DITA files will be validated using rules defined in their associated validation scenario *(on page 798)*.

Check the existence of non-DITA references resources

Extends the validation of referenced resources to non-DITA files.

Include remote resources

Select this option if you want to check that remote referenced binary resources (such as images, movie clips, ZIP archives) exist at the specified location.

Report references to resources outside of the DITA map folder

If selected, it will report any references to DITA resources that are located outside the *main DITA map (on page 3424)* folder.

Report links to topics not referenced in DITA maps

Checks that all the topics referenced by other topics are also linked in the *DITA map*. Also reports related links defined in relationship tables whose target topics are not referenced in the DITA Map.

Report multiple references to the same topic

If selected, it will report warnings when a topic is referenced multiple times in the *DITA map*, unless a unique `@copy-to` attribute is used on the `<topicref>` element for any topic that is referenced multiple times.

For example, it will **not** report a warning if there is a topic referenced twice, but the second `<topicref>` has a `@copy-to` attribute set:

```
<topicref href="topic.dita"/>
.....
 <topicref href="topic.dita" copy-to="topic2.dita"/>
```

On the other hand, it **will** report a warning if there is a topic referenced twice and none of the reference-type elements has a `@copy-to` attribute set or both of them have the `@copy-to` attribute set to the same value:

```
<topicref href="topic.dita" copy-to="topic2.dita"/>
......
 <topicref href="topic.dita" copy-to="topic2.dita"/>
```

Check for duplicate topic IDs within the DITA map context

Checks for multiple topics with the same ID in the context of the entire map.

Report duplicate key definitions

Checks the *DITA map* for multiple key references with the same key defined for them. This is helpful because if you have two different resources with the same value for the `@keys` attribute, all references will point to the first one encountered and the other will be ignored.

Note:
This option takes *key scopes (on page 3239)* into account. For example, if you have something like this:

```
<topicref href="t2.dita" keys="k2"/>
    <topicgroup keyscope="ks">
        <topicref href="t2.dita" keys="k2"/>
    </topicgroup>
```

it will not report the "k2" key as a duplicate because it is defined in a *key scope (on page 3239)* on the second occurrence.

Report unreferenced key definitions

Checks the entire *DITA map* and reports any key definitions that are not referenced anywhere. Note that if the **Use DITAVAL filters** option is selected, this check will search for unreferenced key definitions based upon your selected filter.

Report unreferenced reusable elements

Checks the entire *DITA map* and reports any detected reusable elements that are not referenced anywhere. It looks for elements that have an *ID* specified in the following types of topic references:

- Any `<topicref>` that contains a `@processing-role` attribute set to **resource-only**.
- Any other referenced topic that contains elements that are reused elsewhere through a `@conref` or `@conkeyref`.

Report table layout problems

Looks for table layout problems. The types of errors that may be reported include:

- If a row has fewer cells than the number of columns detected.
- For a *CALS* table, if a cell has a vertical span greater than the available rows count.
- For a *CALS* table, if the number of `<colspecs>` is different than the number of columns detected from the table `@cols` attribute.
- For a *CALS* table, if the number of columns detected from the table `@cols` attribute is different than the number of columns detected in the table structure.
- For a *CALS* table, if the value of the `@cols`, `@rowsep`, or `@colsep` attributes are not numeric.
- For a *CALS* table, if the `@namest`, `@nameend`, or `@colname` attributes point to an incorrect column name.

Identify possible conflicts in profile attribute values

When the profiling attributes of a topic contain values that are not found in parent topic profiling attributes, the content of the topic is overshadowed when generating profiled output. This option reports these possible conflicts.

Report attributes and values that conflict with profiling preferences

Looks for profiling attributes and values that are not defined in the **Profiling / Conditional Text** preferences page *(on page 195)* (you can click the **Profiling Preferences** button to open this preferences page). It also checks if profiling attributes defined as *single-value* have multiple values set in the searched topics.

Additional Schematron checks

Allows you to select a Schematron file that Oxygen XML Editor will use for the validation of DITA resources. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 332)* button, or the browsing actions in the **Browse** drop-down list.

Advanced Tip:
Some APIs are available that retrieve information about DITA keys that are referenced within a topic. The APIs can be called from XSLT Stylesheets (including XML Refactoring operations) or Schematron schemas. For details, see API Documentation: DITAXSLTExtensionFunctionUtil.

Publishing DITA Open Toolkit Project Files

Once a DITA-OT project file is opened in the application, two predefined publishing scenarios become available in the **Configure Transformation Scenario(s)** dialog box *(on page 1600)*:

- **Publish DITA-OT Project (all deliverables)** - Runs the publishing engine and produces output for all deliverables defined in the project file.
- **Publish DITA-OT Project (select deliverable)** - Runs the publishing engine and produces output for only one deliverable specified by the end-user.

Some of the allowed transformation parameters that are relevant to the DITA-OT project file include:

- **project.file** - Specifies the path to the project file.
- **dita-ot.dir** - Specifies the directory where DITA-OT, used in transformation is installed.
- **additional.args** - Specifies the additional arguments used in transformation.
- **deliverable.id** - Specifies the id of the deliverable. This parameter is only available in the **Publish DITA-OT Project (select deliverable)** transformation.
- **jvm.args** - Specifies the JVM arguments used by the transformation for each deliverable. This can be used to increase the memory allocation used by the transformation.

  Example: To set the JVM memory allocation to 5 GB for publishing deliverables, append the following value to the existing ones:

  ```
  -Xmx5G
  ```

  If the "pdf-css-html5" (based on Chemistry PDF CSS processor) deliverable publication fails with an Out Of Memory Error, try appending the `baseJVMArgLine` parameter to the "jvm.args" parameter value. For example:

  ```
  -DbaseJVMArgLine=-Xmx5G
  ```

When editing DITA OT project files in the **Author** visual editing mode, each presented deliverable has an inline button that can be used to individually publish it.

Main Files Support for DITA Open Toolkit Project Files

If you enable main files support at project level *(on page 3368)*, you can choose to detect all top-level DITA Open Toolkit project files and to add them to the Main Files folder. You could also manually add the top-level

files for your DITA-OT project in the Main Files folder. The benefit of this is that whenever you rename or move files in the **Project** view, the references to those resources will automatically be updated.

Tip:
The Referenced/Dependent Resources view *(on page 3370)* also works for DITA-OT project files.

Editing Contexts Detected from DITA Open Toolkit Project Files

Once a DITA-OT project file is added to the Main Files folder, the **Context** drop-down menu on the **DITA Maps Manager** toolbar will contain context DITA maps defined in the project file and the  **Profiling/Conditional Text** menu will contain filter pairs gathered from the project file. When you select one of them in the drop-down menu, the application gathers the keys from the context DITA map and applies the filters specified in that context.

DITA Specialization Support

DITA is designed to let you design new markup and new document types that allow any general-purpose DITA processor to process documents that use the new markup. This in turn enables blind interchange of DITA documents from any source. In particular, in the context of a map, you can combine topics of any type and get usable results from any general-purpose DITA processor. Specialization is the one truly unique and distinguishing aspect of DITA. Even if you have no use for any aspect of DITA modularity or reuse, you still have a use for specialization simply because it enables reliable interchange in a way that no other XML application does.

For detailed information and step-by-step tutorials about DITA specializations, see DITA 4 Practitioners: DITA Configuration and Specialization Tutorials.

In addition, the topics in this section contain information about using DITA specializations in Oxygen XML Editor.

Integrating a DITA Specialization

A DITA specialization can have its document type defined with any of the following::

- **DTD** - For configuration and specialization tutorials, see http://dita4practitioners.github.io/dita-specialization-tutorials/. A small sample plugin is also available here: https://github.com/oxygenxml-incubator/dita-ot-specialization-plugin-sample/.
- **XSD** - For configuration and specialization tutorials, see http://dita4practitioners.github.io/dita-specialization-tutorials/.
- **Relax NG** - For more information, see the following presentation: Creating DITA-OT Constraint/Specialization Plugins. For Relax NG coding requirements, see https://www.oxygenxml.com/dita/1.3/specs/archSpec/base/relax-ng-requirements.html.

A DITA specialization may optionally include specialized processing, that is new XSLT template rules that match the extension part of the `@class` attribute values of the new elements, and thus extend the default processing available in the DITA Open Toolkit.

To integrate a DITA specialization into Oxygen XML Editor, use one of the following methods:

DITA-OT Plugin Method

> **CAUTION:**
> Oxygen XML Editor support engineers do not officially offer support and troubleshooting assistance for custom DITA-OT distributions or custom installed DITA-OT plugins. If you discover any issues or inconsistent behavior while using a custom DITA-OT or a DITA-OT that contains custom DITA-OT plugins, you should revert to the default built-in DITA-OT.

If the DITA specialization is available as a DITA Open Toolkit plugin, follow this procedure:

1. Copy the additional *plugin* to the location of the DITA-OT version you are using (by default, *DITA-OT-DIR*`\plugins` directory).

   > **Important:**
   > The application needs to have full write access permissions to the DITA-OT directory.

2. If Oxygen XML Editor was installed in the default location, you may need to restart and run it as an administrator.
3. Select the **Configure Transformation Scenario(s)** *(on page 1600)* action from the **DITA Maps Manager** toolbar (you could also use the same action on the main toolbar or open the **Transformation Scenarios** view *(on page 1607)*).
4. Select the **Integrate/Install DITA-OT Plugins** transformation scenario *(on page 3287)*.

   > **Tip:**
   > If you don't see that scenario in the **Configure Transformation Scenario(s)** *(on page 1600)* dialog box or **Transformation Scenarios** view *(on page 1607)*, click the **Settings** button and select the **Show all scenarios** option, but don't forget to change it back to **Show only the scenarios available for the editor** after you are finished with this procedure.

5. Apply the scenario *(on page 1600)*.
6. Check the **Results** panel at the bottom of the application to make sure the build was successful.
7. Restart Oxygen XML Editor with your normal permissions.

> **Tip:**
> Oxygen XML Editor detects new document templates *(on page 385)* contributed by the DITA-OT plugin as long as you do the following:

1. Create a new folder called **template_folders** inside your DITA OT plugin's folder. For example: `DITA-OT-DIR\plugins\my_custom_plugin\template_folders`.
2. Create one or more subfolders inside the **template_folders** directory that contain the new document templates. The new document templates found in those subfolders will be available in the **New** document wizard.

Alternative Methods

If the DITA specialization is not available as a DITA-OT plugin, you have the following options:

- If the DTDs that define the extension elements are located in a folder outside the DITA Open Toolkit folder, add new rules to the DITA-OT catalog file. These rules are meant for resolving the DTD references from the DITA files that use the specialized elements to that folder. This allows for correct resolution of DTD references to your local DTD files and is needed for both validation and transformation of the *DITA maps* or topics. The DITA-OT catalog file is called `catalog-dita.xml` and is located in the root folder of the DITA Open Toolkit.
- If there is specialized processing provided by XSLT stylesheets that override the default stylesheets from DITA-OT, these new stylesheets must be called from the DITA-OT Ant build scripts.

  Important:
  If you are using DITA specialization elements in your DITA files, it is recommended that you activate the **Enable DTD/XML Schema processing in document type detection** option in the **Document Type Association** preferences page *(on page 145)*.

- You could create your own document templates *(on page 385)*, store them in a custom directory, then add that directory to the list of template directories that Oxygen XML Editor uses by adding the directory to the list in the Document Templates Preferences *(on page 174)* page.

DITA Configuration and Specialization Tutorials

Editing DITA Map Specializations

In addition to recognizing the default *DITA map (on page 3419)* formats (`<map>` and `<bookmap>`), the **DITA Maps Manager** view *(on page 3073)* can also be used to open and edit specializations of *DITA maps*.

All advanced editing actions available for the map (such as insertion actions or editing properties) allow you to specify the element in an editable combo box. The elements that initially appear in the combo box are all the elements that are allowed to appear at the insert position for the given specialization.

The topic titles rendered in the **DITA Maps Manager** view *(on page 3073)* are collected from the target files by matching the `@class` attribute and not a specific element name.

When editing DITA specializations of maps in the main editor, the insertions of topic reference, topic heading, topic group and conref actions should work without modification. For the table actions, you have to modify each action manually to insert the correct element name at the cursor position. You can go to the **DITA Map** document type from the **Document Type Association** preferences page *(on page 145)* and edit the table actions to insert the element names as specified in your specialization. See Creating a Framework through the Configuration Dialog *(on page 2248)* for more details.

Related Information:
DITA Configuration and Specialization Tutorials
Integrating a DITA Specialization *(on page 3363)*

Editing DITA Topic Specializations

In addition to recognizing the default DITA topic formats, topic specializations can also be edited in **Author** mode.

The content completion should work without additional modifications and you can choose the tags that are allowed at the cursor position.

The CSS styles used for rendering the elements should also work on the specialized topics without additional modifications.

The toolbar/menu actions should be customized to insert the correct element names. You can go to the DITA document type from the **Document Type Association** preferences page *(on page 145)* and edit the actions to insert the element names, as specified in your specialization. See Creating a Framework through the Configuration Dialog *(on page 2248)* for more details.

Translating DITA Projects Overview

This topic contains some general information about translating DITA content and is meant to help those who do not store their DITA projects through a **Content Management System (CMS)** or other type of service that already includes their own translation support.

Choosing a Translation Agency

To minimize translation costs, it is recommended to choose a translation agency that is able to handle DITA content directly, without requiring you to convert the content to some intermediary format. This means that you benefit from the DITA reusable content features *(on page 3212)*.

If you plan to translate your DITA project, it is also recommended that you contact a DITA-aware translation agency as early in your process as possible because translation agencies who translate DITA content directly usually need to have a preliminary discussion about how your project is structured, which terms need to be

skipped when translating, how various measuring units are translated, how content is reused, your metadata strategy, and how screenshots are handled. Those discussions may influence the way that you organize and write your DITA content.

Note:
If your translation agency does not directly handle DITA content, there are commercial tools that can be used to convert **DITA** to **XLIFF** (for example, https://www.maxprograms.com/products/fluenta.html).

Optimizing Content for Translation

In general, there are three main principles to take into account when writing DITA content that will be translated:

1. Use a controlled vocabulary (for example, the Simplified Technical English vocabulary).
2. Avoid reusing inline elements other than product names. The following *DITA Users List* discussion describes the reasons for this: https://lists.oasis-open.org/archives/dita/201301/msg00029.html.
3. Avoid profiling/filtering content at inline level, for similar reasons.

General DITA Project Structure

It is usually considered best practice to organize your DITA maps/topics in a separate folder for each language. One folder that contains the English version of all of your DITA resources and a separate folder for each of the other languages you will translate with equivalent DITA resources translated in that specific language.

General Translation Workflow

When translating DITA content, the most common workflow involves these steps:

1. Create your content in the primary language.
2. Before each release, you gather all the DITA files that have been changed and need to be translated. The DITA Translation Package Builder Add-on *(on page 2687)* could be handy for this.
3. Send a copy of the relevant DITA files to the translation agency (known also as "localization service provider").
4. Receive translated DITA content back from the translation agency and integrate it in each language-specific project folder *(on page 3367)*.

Publishing Translated Content

All of your translated DITA maps and topics should have the **xml:lang** attribute set with the appropriate value on the root element. Along with the actual translated content, the published output may also contain static text (such as the word **Table** followed by the table number, **Figure** following by the number, or **Note** appearing before the content of each DITA `<note>` element). The **DITA Open Toolkit** includes support for various languages for HTML-based output and PDF-based output. You can also add support for other languages:

Globalizing DITA Content: Customizing Generated Text. For information about how to add a new language to the **Oxygen WebHelp Responsive** output, see Adding a New Language *(on page 1749)*.

Liability

Translation agencies usually do not assume any liability for incorrectly translated content. If possible, it is recommended to have someone who is familiar with the particular language be responsible for reviewing and accepting the translated content. For example, if your company has regional headquarters located in various countries, perhaps someone from each headquarters could review the translated content.

Other Resources

Here are some links to other resources that might help you with translating DITA projects:

- DITA Translation: Organizing Your DITA Files
- DITA Translation: Using XLIFF to Translate DITA Projects
- WhP Localization Services Blog Page
- Webinar: **DITA Project Management, Validation, and Translation in a Docs as Code Environment**

Main Files Support in DITA

Oxygen XML Editor includes a feature that allows you to define *Main Files (on page 3421)* at project level. This feature is typically used in Oxygen XML Editor for XML documents to determine the context for operations such as validation, content completion, refactoring, searches, or displaying components collected from various modules. For DITA projects, this feature has a more limited purpose in Oxygen XML Editor since it is mainly used to provide the means for updating references to moved or renamed resources.

Since you can move or rename DITA resources (such as topics and maps) in the **DITA Maps Manager** *(on page 3073)*, the *root map (on page 3424)* is used as the scope to update all the references to the moved or renamed resources. However, you do not have this option for non-DITA resources (such as folders, images, HTML files, audio, video, text files, Markdown documents) since they do not appear in the **DITA Maps Manager**. Also, when moving DITA resources in the **DITA Maps Manager**, you have to do it one at a time.

You can use the *Main Files* support in DITA to update all the references to moved or renamed resources in the scope of the *Main Files*, and since the *root map (on page 3424)* will be set as the *Main File*, you achieve the same result as if you were moving or renaming them in the **DITA Maps Manager**. It also allows you to move multiple DITA resources (or entire folders) at once in the **Project** view *(on page 413)*, instead of the **DITA Maps Manager**, while still giving you the option of updating all the references.

How to Enable Main Files Support in DITA

To use the *Main Files* support in DITA, follow these steps:

1. Go to the **Project** view *(on page 413)* and enable *Main Files* support with one of the following methods:
   - Select **Enable Main Files Support** from the **Settings** menu in the top-right corner.
   - Select **Enable Main Files Support** from the contextual menu of the project root folder. If a disabled *Main Files* folder exists, you can also select that option from its contextual menu.
   - Click the **Enable** button in the tooltip located at the bottom. This tooltip window is displayed when the *Main Files* support is disabled. Clicking the **Read more** link takes you to the user guide. Clicking the **Enable** button opens the **Enable Main Files** dialog box. This dialog box contains general information about the **Main Files Support** and allows you to enable it.

   > **Warning:**
   > Once you close this window tip, Oxygen XML Editor hides it for all projects. You can make the window tip reappear by resetting Oxygen XML Editor to its default settings *(on page 323)*. However, doing so will result in you losing your customized options.

2. Add the main DITA map (*root map*) *(on page 3424)* to the Main Files folder by doing one of the following:
   - Right-click the project root folder and select **Detect Main Files**.
   - Right-click the *Main Files* folder and select **Detect Main Files from Project**.
   - If you enabled the *Main Files* support from the tooltip at the bottom of the **Project** view, you can also use the **Detect and Enable** button in the resulting dialog box to detect the *main files* from the current project.
   - Manually add the *root map (on page 3424)* to the *Main Files* folder by doing one of the following:
     - Right-click a file from your project and select **Add to Main Files** from the contextual menu (or simply drag and drop it into the *Main Files* folder).
     - Select **Add Files** or **Add Edited File** from the contextual menu of the *Main Files* folder.

   > **Tip:**
   > You can set multiple maps in the *Main Files* folder and all of them will automatically be added to the list of root maps you can select from the drop-down menu in the **DITA Maps Manager** toolbar *(on page 3077)*.

3. [Alternative] If you have a defined DITA Open Toolkit project XML file *(on page 3362)* you can add it to the *Main Files* folder. Once you do that the application will know the dependencies between all resources directly and indirectly referenced from the project file, including DITA maps, topics, binary resources and DITAVAL filter files.

Moving or Renaming Non-DITA Resources and Updating the References to Them

With the *Main Files* support enabled, you can move or rename non-DITA resources (such as folders, images, HTML files, audio, video, text files, Markdown documents) or move multiple normal DITA resources (or entire

folders) in the **Project** view *(on page 413)* and Oxygen XML Editor will offer the option of updating all the references to the moved or renamed resources in the scope of the *Main Files* (in this case, the *main DITA map (root map) (on page 3424)*).

To move or rename non-DITA resources (or move multiple DITA resources) and update the references to them, follow these steps:

1. Enable *Main Files* support and add your *root DITA map (on page 3424)* to the *Main Files* folder as described in the How to Enable Main Files Support in DITA *(on page 3368)* section above.
2. Go to the **Project** view *(on page 413)*, and use one of the following methods to move or rename the resources:

   Moving Resources

   To move resources in the **Project** view *(on page 413)*, do one of the following:
   - Simply drag and drop the resource to the new location in the tree structure (the **Enable drag-and-drop in Project view** option must be selected in the **View** preferences page *(on page 315)*).
   - Use the **Cut**, **Copy**, and **Paste** actions from the contextual menu.
   - Right-click the resource and select **Refactoring > Move resource** action from the contextual menu. Note that this method also allows you to specify a new name and destination path in the **Move resource** dialog box.

   Result: In all cases, a **Move resource** dialog box will be presented.

   Renaming Resources

   To rename resources in the **Project** view *(on page 413)*, do one of the following:
   - Select the resource and press **F2**, or simply left-click again, until the in-place editor allows you to change the file name.
   - Right-click the resource and select **Rename** or **Refactoring > Rename resource** .

   Result: In all cases, a **Rename resource** dialog box will be presented.
3. Make sure the **Update references of the moved resource(s)** option is selected in the resulting **Move** or **Rename** dialog box and keep the scope as **main files** to make sure all the references to the moved or renamed resource are updated.

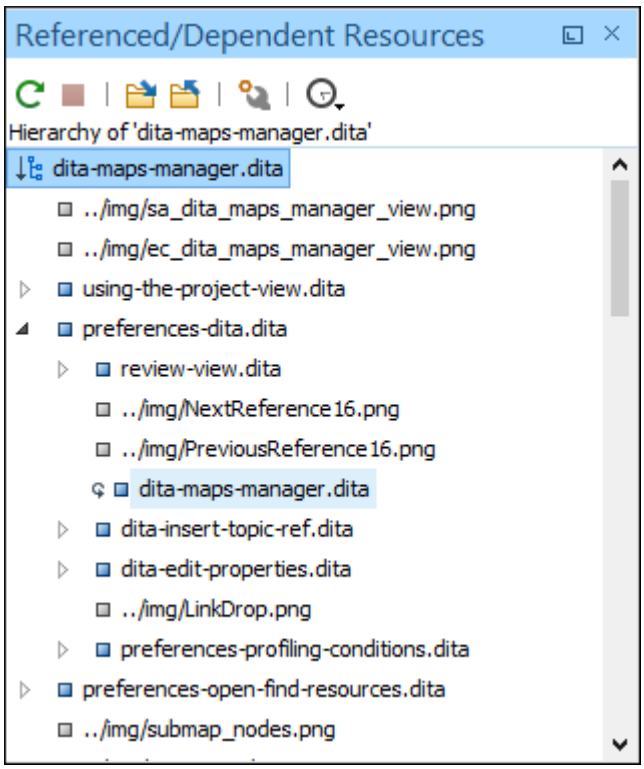
DITA Referenced/Dependent Resources View

The **Referenced/Dependent Resources** view displays the *hierarchy* or *dependencies* for resources included in an XML document. For DITA resources, it will only show direct references, so resources that are indirectly referenced through keys are not presented in the hierarchy or dependencies tree.

To see the references or dependencies for a DITA resource (maps or topics), right-click a resource in the **Project** view *(on page 413)* and either select **Show referenced resources** or **Show dependent resources**.

If you want to view the dependencies for a media resource (such as images) directly referenced in a DITA topic, click the **Show dependencies for** button on the toolbar of the **Referenced/Dependent Resources** view, select the **All files** filter in the file browser, find the particular resource, and double-click it.

Figure 839. Referenced/Dependent Resources View



The following actions are available on the toolbar of the **Referenced/Dependent Resources** view:

Refresh

Refreshes the hierarchical structure.

Stop

Stops the computing.

Show hierarchy for

Computes the hierarchical structure of the references for a resource.

Show dependencies for

Computes the structure of the dependencies for a resource.

Configure dependencies search scope

Allows you to configure a scope to compute the dependencies structure. You can restrict the scope to the current project or to one or multiple *working sets (on page 3425)*. If the **Use only Main Files, if enabled** checkbox is selected, the scope of the search is restricted to the **Main Files** directory *(on page 3368)*.

History

Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu for a resource listed in the **Referenced/Dependent Resources** view contains the following actions:

Open

Opens the resource. You can also double-click a resource in the hierarchical structure to open it.

Go to reference

Opens the source document where the resource is referenced.

Copy location

Copies the location of the resource.

Move resource

Opens the **Move resource** dialog box where the following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - As long as **Main Files** support is enabled *(on page 3368)*, you can select this option to update the references to the resource you are moving, in accordance with the new location and name. A **Preview** option is available that allows you to see what will be updated before selecting **Move** to process the operation.

Rename resource

Opens the **Rename resource** dialog box where the following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references of the renamed resource(s)** - As long as **Main Files** support is enabled *(on page 3368)*, you can select this option to update the references to the resource you are renaming. A **Preview** option is available that allows you to see what will be updated before selecting **Rename** to process the operation.

Show referenced resources

Shows the references for the selected resource.

Show dependent resources

Shows the dependencies for the selected resource.

Add to Main Files

Adds the currently selected resource in the **Main Files** directory.

Expand More

Expands more of the children of the selected resource from the structure.

Collapse All

Collapses all children of the selected resource from the structure.

Tip:
When a recursive reference is encountered in the view, the reference is marked with a special icon .

Search and Rename Actions for IDs in DITA

Oxygen XML Editor allows you to search references to ID attributes (either direct references using the `@href` and `@conref` attributes or indirect references using `@keyref` or `@conkeyref` attributes) or to rename the id attribute in all the declared and referenced locations. The main benefit of this feature is the fact that it allows you to rename `@id` attributes (or search for their references) in the scope of the entire project. It also works for IDs defined inside DITA maps and then referenced in maps and topics.

In **Author** mode, these operations are available for DITA documents in the contextual menu (grouped in the **Manage IDs** submenu). In **Text** mode, these actions are also available in the **Quick Assist** menu. To access it, place the cursor inside the value of an `@id` attribute and click the yellow light bulb icon.

The possible actions include:

Rename in

Renames the ID and all of its occurrences. Selecting this action opens a dialog box where you insert the new ID value and choose the scope of the rename operation. For a preview of the changes you are about to make, click **Preview**. This opens the **Preview** dialog box, which presents a list with the files that contain changes and a preview zone of these changes.

Rename in File (Available in the Text mode only)

Renames the ID you are editing and all its occurrences in the current file.

Search References

Searches for the references of the ID. By default, the scope of this action is the current project.

Search References in

Searches for the references of the ID and you can choose the scope of the operation or configure working sets to use for the scope.

Search Declarations (Available in the Text mode only)

Searches for the declaration of the ID reference. By default, the scope of this action is the current project.

Search Declarations in (Available in the Text mode only)

Searches for the declaration of the ID reference and you can choose the scope of the operation or configure working sets to use for the scope.

Search Occurrences in file

Searches for the declaration and references of the ID in the current document and presents the results in the message panel at the bottom of the application.

Change scope (Available in the Quick Assist menu in Text mode only)

Opens a dialog box where you can choose the scope of the operation or configure working sets to use for the scope.

Tip:
A quick way to go to the declaration of an ID in **Text** mode is to move the cursor over an ID reference and use the **Ctrl + Single-Click (Command + Single-Click on macOS)** navigation.

Selecting an ID that you use for search or refactor operations differs between the **Text** and **Author** modes. In the **Text** mode, you position the cursor inside the declaration or reference of an ID. In the **Author** mode, Oxygen XML Editor collects all the IDs by analyzing each element from the path to the root. If more IDs are available, you are prompted to choose one of them.

Related Information:
Main Files Support in DITA *(on page 3368)*

Metadata

Metadata is a broad concept that describes data that explains or identifies other data. Metadata can be used for many purposes, from driving automation of document builds to enabling authors and readers to find content more easily. DITA provides numerous types of metadata, each of which is used and created differently. Some of the most important forms of metadata in DITA are topic and taxonomy.

Topic Metadata

Topic metadata describes the topic and what it is about. Topic metadata can be inserted in the `<prolog>` element of a topic or inside the `<topicref>` element that points to a topic from a map. In other words, metadata about the topic can be asserted by the topic itself, or can be assigned to it by the map that includes it in the build. This allows multiple maps to assign different metadata to the same topic. This may be appropriate when you want to describe a topic differently in various documents.

Taxonomy and Subject Scheme

A taxonomy is a controlled vocabulary. It can be used to standardize how many things in your content and metadata are named. This consistency in naming can help ensure that automated processes work correctly, and that consistent terminology is used in content, and in metadata. In DITA, taxonomies are created using *subject scheme maps (on page 3424)*. When you are authoring, many of the values you choose from have been defined in *subject scheme maps*.

Migrating MS Office Documents to DITA

Oxygen XML Editor integrates the entire DITA for Publishers plugins suite and provides some possibilities for migrating content from Microsoft Office® (and other Office-type formats) to DITA. There are also possibilities for migrating various other types of formats. For more information, see Migrating Various Document Formats to and from DITA *(on page 3377)*.

Migration from Office-type formats to XML is rarely perfect and manual changes may need to be made to the converted content, but the methods described below should help you find the best approach for your particular case.

Oxygen's Batch Documents Converter Add-on (Multiple Documents)

The Oxygen Batch Documents Converter add-on *(on page 2657)* can be installed in Oxygen XML Editor to provide the ability to convert one or more documents to various formats.

For more details about the main stages of the Word to DITA migration using the Batch Documents Converter add-on, see the following blog post: Migrating MS Word to DITA using Batch Documents Converter.

Note:
The Batch Documents Converter add-on is the recommended way to convert one or more Word documents to DITA content.

Smart Paste (Single Document)

1. Open the document in MS Office (or other similar application), select all the content, and copy it.
2. Open Oxygen XML Editor and create a new DITA topic.
3. Paste the selected content in **Author** mode. The *Smart Paste* functionality *(on page 623)* will attempt to convert the content to DITA structure.

HTML to DITA (Single Document)

1. Save your document as HTML.
2. Once you have converted it to HTML, you have several possibilities:
   - In Oxygen XML Editor, select **File > Import/Convert > HTML File to XHTML** to import it as XHTML. Then, open the XHTML in Oxygen XML Editor and use one of the **XHTML to DITA** transformation scenarios *(on page 1411)* to convert the content to DITA structure.
   - Open the HTML file in any web browser, select all of its content, and copy it. Then, open Oxygen XML Editor, create a new **DITA** topic, and paste the selected content in **Author** mode. The *Smart Paste* functionality *(on page 623)* will attempt to convert the HTML content to DITA structure.

Word to *LibreOffice* to DITA (Single Document)

1. Open the document in the *LibreOffice* application and save it as **DocBook**.
2. Open the **DocBook** document in Oxygen XML Editor.

3. Run the built-in **DocBook to DITA** transformation scenario *(on page 1502)*.
4. You may need to make some manual adjustments for elements that could not be mapped.

Word to DITA using DITA For Publishers (Single Document)

1. Save the document in the MS Word DOCX format.
2. Open it in the **Archive Browser** view *(on page 2126)* in Oxygen XML Editor and then open the **document.xml** file contained in the archive.
3. Run the built-in **DOCX DITA** transformation scenario. This scenario runs a build file over the DOCX archive and should produce a DITA project that contains a *DITA map* and multiple topics.
4. You may need to do some manual reconfiguration to map DOCX styles to DITA content. The XSLT conversion is part of the **DITA For Publishers** plugin and there is documentation for it available here: http://www.dita4publishers.org/d4p-users-guide/user_docs/d4p-users-guide/word2dita/word2dita-intro.html.

Word to DocBook to DITA (Multiple Documents)

1. Use a tool to convert the documents to **DocBook**. For example, *Pandoc* is a free document converter engine that can convert **DOCX** documents to **DocBook** and according to *Pandoc's* manual, you can specify multiple input files and use wildcards in the commands.
2. Save the newly converted **DocBook** documents somewhere in your project.
3. Perform a batch transformation *(on page 1605)* on all the newly converted **DocBook** documents:
    a. Select all the **DocBook** documents in the **Project** view *(on page 413)*.
    b. Right-click the selected files and choose **Transform >** **Configure Transformation Scenario(s)**.
    c. Apply the built-in **DocBook to DITA** transformation scenario *(on page 1502)*.
4. You may need to make some manual adjustments in the resulting documents for elements that could not be mapped.

Word to HTML/Markdown to DITA (Multiple Documents)

1. Use a tool to convert the documents to **HTML** or **Markdown**. For example, Pandoc is a free document converter engine that can convert DOCX documents to those formats.
2. Use **Oxygen's Batch Converter add-on** *(on page 2657)* to convert the documents to **DITA**.
3. You may need to make some manual adjustments in the resulting documents for elements that could not be mapped.

Migrating Excel and Other Types of Spreadsheets to DITA

There are two possibilities for converting Microsoft Excel (or other similar types of documents) to DITA:

- Copy the spreadsheet content and paste it in a DITA topic in **Author** mode. The *Smart Paste functionality (on page 623)* will attempt to convert the content to DITA.
- Use **Oxygen's Batch Converter add-on** *(on page 2657)* to convert one or more spreadsheet documents to **DITA**.

Migrating Various Document Formats to and from DITA

When organizations decide to use DITA for structuring, developing, managing, or publishing content, they usually already have content written in other formats and need to convert it to DITA. There are a variety of possibilities for a conversion to DITA, depending on the original format of the content.

Migration from other formats to DITA is rarely perfect and manual changes may need to be made to the converted content, but the methods described below should help you find the best approach for your particular case.

Migrating Microsoft Office and Other Similar Types of Documents to DITA

There are various possibilities for migrating content from Microsoft Office® (and other Office-type formats) to DITA. For details, see Migrating MS Office Documents to DITA *(on page 3375)*.

Migrating DocBook Content to DITA

The Oxygen Batch Documents Converter add-on *(on page 2657)* can be used for migrating one or multiple DocBook documents to DITA.

The provided **DocBook to DITA** conversion contains an option named **Create DITA maps from DocBook documents containing multiple sections**. When this option is selected, all sections from your DocBook document will be separated into individual DITA topics and referenced in a DITA map.

Migrating Google Docs to DITA

There are several possibilities to convert Google Docs to DITA:

- Copy the content from Google Docs and paste it in an open DITA topic in **Author** mode. The *Smart Paste* functionality *(on page 623)* will attempt to convert the content to DITA.
- Save the Google document as OpenDocumentFormat (**ODF**), then open it in the free *LibreOffice* application and save it as **DocBook**. Next, open the **DocBook** document in Oxygen XML Editor and run the built-in transformation scenario called **DocBook to DITA** *(on page 1502)*.
- If you want to convert multiple Google documents at once, save the documents as HTML, then use **Oxygen's Batch Documents Converter add-on** *(on page 2657)* to convert the documents to **DITA**.

In all cases, you may need to make some manual adjustments in the resulting documents for elements that couldn't be mapped.

Migrating Markdown Content to DITA

There are several possibilities to convert Markdown content to DITA:

- The DITA Open Toolkit publishing engine bundled with Oxygen XML Editor allows you to reference Markdown files directly in a DITA map and either publish them directly or export the Markdown files to DITA one by one. For details, see Working with Markdown Documents in DITA *(on page 3203)*.
- If you want to convert multiple Markdown files at once, you can use **Oxygen's Batch Documents Converter add-on** *(on page 2657)* to convert the documents to **DITA**.

Migrating HTML Content to DITA

There are several possibilities to convert HTML content to DITA:

- Copy the HTML content and paste it in an open DITA topic in **Author** mode. The *Smart Paste* functionality *(on page 623)* will attempt to convert the content to DITA.
- Convert the HTML file to XHTML by selecting **File > Import/Convert > HTML File to XHTML**. Then, open the XHTML file and use one of the **XHTML to DITA** Transformation Scenarios *(on page 1411)* to convert the content to DITA.
- If you want to convert multiple HTML files at once, you can use **Oxygen's Batch Converter add-on** *(on page 2657)* to convert the documents to **DITA**.

Migrating Unstructured FrameMaker to DITA

There is a blog post that details various possibilities for converting Unstructured FrameMaker content to DITA: Migrating Unstructured FrameMaker to DITA.

Migrating MadCap Content to DITA

This open-source project contains such a stylesheet that attempts to convert a Flare project to DITA XML along with instructions on how to use it. As an alternative, some recent MadCap versions seem to have facilities to export content directly to DITA.

Migrating Confluence to DITA

To migrate Confluence content to DITA, first export the content to HTML. For this, log in to your Confluence account and navigate to the specific space that you want to export. Then go to **Space Settings > Export space** and choose to export it as HTML.

You can then use **Oxygen's Batch Documents Converter add-on** *(on page 2657)*, selecting the **Confluence to DITA** action, to convert the exported `index.html` file into a DITA map with topics.

Migrating LaTex to DITA

You may use a third-party application (such as Pandoc) to convert LaTex content to Word or HTML. Then, you can use the **Oxygen's Batch Documents Converter add-on** *(on page 2657)* to convert it to DITA XML.

Migrating Other Formats to DITA

You may find third-party applications (such as Pandoc) that can convert your content to HTML or to some kind of XML format like DocBook. Once you have HTML or DocBook content, you can convert them to DITA using one of the methods described above.

Migrate from DITA to Confluence and Other Formats

There are various possible methods available for converting DITA content to Confluence and other formats (such as Microsoft Word or HTML). For details and ideas for some of the possible methods, see the **DITA to Confluence** blog post.

Resources

For more information about migrating to DITA, see the following resources:

How to Count Words in DITA Topics or Maps

There are various ways to count words in Oxygen XML Editor:

- Open a DITA topic in the **Author** visual editing mode, right-click anywhere in the editor, and select **Text > Count Words**.
- Open a DITA map in the **DITA Maps Manager** view. Click the  **Open map in editor with resolved topics** toolbar button. In the newly opened DITA map, right-click anywhere in the editor and select **Text > Count Words**.

- Open a DITA map in the **DITA Maps Manager** view. Click the **Configure Transformation Scenarios** toolbar button and choose the **DITA Map Metrics Report** transformation scenario.

> **Tip:**
> Along with the word count, the DITA Map Metrics Report Transformation *(on page 3284)* provides additional information (such as the number of processed maps and topics, content reuse percentage, the number of elements, attributes, words, and characters used, and more).

DITA 1.3 Support

Starting with version 17.1, Oxygen XML Editor includes support for some DITA 1.3 features.

The Oxygen XML Editor publication of the full DITA 1.3 specifications can be found at https://www.oxygenxml.com/dita/1.3/specs/index.html#introduction/dita-release-overview.html.

The following table is a list of DITA 1.3 features and their implementation status in Oxygen XML Editor:

Table 55. DITA 1.3 Features Implementation Status

Feature	Editing	Publishing [DITA Open Toolkit 4.1.2 is used]
DITA 1.3 DTD, XML Schema, and Relax NG-based maps/topics/tasks/references, etc.	New DITA 1.3 document templates. By default, DITA topics and maps that do not specify version in the DOCTYPE declaration are also considered to be DITA 1.3 Specific annotations presented in the content completion assistance window and documentation tooltips for all new DITA 1.3 elements	N/A
Learning Object and Group maps	New document templates	No specific support implemented
Troubleshooting specialization	Create and edit new troubleshooting topics	No specific support implemented
XML markup domain	Validation and Content Completion	Special rendering in PDF and XHTML-based outputs
Equation and MathML domain	Validation and content completion Display and Insert equations	Special rendering in PDF and XHTML-based outputs

Table 55. DITA 1.3 Features Implementation Status (continued)

Feature	Editing	Publishing [DITA Open Toolkit 4.1.2 is used]
SVG domain	Validation and content completion Display referenced SVG content	Special rendering in PDF and XHTML-based outputs
Other new DITA 1.3 elements (**div**, **strike-through**, **overline**, etc.)	Validation and Content Completion	Special rendering in PDF and XHTML-based outputs
Release management domain	Validation and Content Completion	No specific support implemented
Scoped keys *(on page 3239)*	Define key scopes Validate and check for completeness Resolve **keyrefs** and **conkeyrefs** taking key scopes into account Key scope information is displayed in a tooltip when hovering over an item in the **DITA Maps Manager**	Partially implemented (Various issues may still be encountered)
Branch filtering *(on page 3241)*	Display, create, and edit `<ditavalref>` elements	Partially implemented (Various issues may still be encountered)
Key-based cross deliverable addressing	Special display for references to *DITA maps* with `scope="peer"` and a defined *keyscope* Gather and present keys from peer maps	Not implemented.
Shorthand to address syntax that identifies elements in the same topic	Properly resolved for validation, links, and conrefs	Implemented
Various table attributes (**orientation**, **rotation**, **scope**, and **headers** on cells)	Not implemented in the Table Properties action support. However, attributes can be changed from the Attributes view	Not implemented

Table 55. DITA 1.3 Features Implementation Status (continued)

Feature	Editing	Publishing [DITA Open Toolkit 4.1.2 is used]
New Map **topicref** attributes (**cascade**, **deliveryTarget**)	Allow setting new attributes, propose proper values for them	Implemented

Related information

Watch our DITA 1.3 video tutorial for more information about key scopes and branch filtering.

DITA 2.0 Support

Starting with version 23, Oxygen XML Editor includes support for some DITA 2.0 features. To enable this support, go to the **Options > Preferences > DITA** page and select the **Enable DITA 2.0 Editing Support (Experimental)** checkbox. Enabling it results in DITA 2.0 topic and map templates being available in the **New** document wizard *(on page 377)*.

The following table is a list of DITA 2.0 features and their implementation status in Oxygen XML Editor. The list of proposed DITA 2.0 changes is published here: https://www.oasis-open.org/committees/download.php/65626/DITA-2.0-proposals.pdf.

Table 56. DITA 2.0 Features Implementation Status

Feature	Editing	Publishing [DITA Open Toolkit 4.1.2 is used]
DITA 2.0 DTD, and Relax NG-based maps/topics/tasks/references, etc.	New DITA 2.0 document templates.	Also supported by the publishing engine.
Other new DITA 2.0 elements (include, etc.)	Validation and Content Completion.	Special rendering in PDF and XHTML-based outputs: https://www.dita-ot.org/dev/reference/dita-v2-0-support.html.
Profiling attributes defined using the new `@specializations` attribute.	Profiling attributes defined using the new `@specializations` attribute are recognized by the application.	Also supported by the publishing engine.

23.

Scripting Oxygen

Although Oxygen XML Editor is mostly intended to be a visual editing tool, the all platforms distribution is bundled with a `scripts` subfolder that contains scripts to automate and run various utilities from a command line.

To run any of these scripts, you are required to purchase a special scripting commercial license. Trial scripting licenses are also available, by request, for clients who are interested in testing the scripts for their particular workflows. Once you have a scripting license key available, you should copy the license key to a file named `scriptinglicensekey.txt` and save it in the main application directory (the parent directory of the "scripts" directory).

For more information about the **Oxygen Scripting** support, watch our Webinar: **Automate XML processing with Oxygen XML Scripting**.

DITA Validate and Check For Completeness

> **Attention:**
> This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

The **Validate and Check For Completeness** *(on page 3118)* action that is available on the toolbar of the **DITA Maps Manager** view provides the ability to validate a DITA map or a DITA Open Toolkit project file with a large array of settings. The settings dialog box has an **Export settings** option that can be used to export the settings to an XML configuration file. Once the settings are exported, you can use the `validateCheckDITA.sh` script (found in the `scripts` subfolder inside **Oxygen's** installation directory) to run a validation on a DITA map or DITA Open Toolkit project file and report the results in a separate XML document.

Sample Command-Line Arguments for the Validate and Check for Completeness Script:

```
sh scripts/validateCheckDITA.sh -i inputFile [-c contextId] [-s settingsFile] [-r reportFile]
```

A public example of using such a script as a GitHub action for reporting errors in pull requests on DITA project can be found here: https://github.com/oxygenxml/blog/blob/master/.github/workflows/validate-check-completion.yml. The GitHub action calls a Gradle script target named `runValidation`: https://github.com/oxygenxml/blog/blob/master/build/build.gradle.

Transform

Attention:

- This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.
- To execute a scenario based on WebHelp using this script, in addition to the scripting commercial license, you are required to purchase an Oxygen XML WebHelp license or a Oxygen Publishing Engine license.
- To execute a scenario based on Chemistry using this script, in addition to the scripting commercial license, you are required to purchase an Oxygen PDF Chemistry license or a Oxygen Publishing Engine license.

The **Transform** script (`transform.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) helps you to execute a transformation scenario. You can run the scenarios for the existing document types (frameworks) *(on page 3420)* without setting a scenarios file, but for others, you have to specify a specialized scenarios file or a project file that contains scenarios.

You can export transformation scenarios from Oxygen XML Editor into a specialized scenarios file by using the **Export selected scenarios** action from the **Transformation Scenarios** view or using the **Export Global Transformation Scenarios** action from the **Options** menu.

Arguments for the Transform Script

```
sh scripts/transform.sh -i inputFile -sn scenarioName [-s scenariosFile] [-v]
```

-i inputFile

The input file that the transformation scenario is applied to.

-sn scenarioName

The name of the transformation scenario to be executed.

-s scenariosFile

The name of a file that contains additional scenarios. It can be a specialized scenarios file or a project file that contains project transformation scenarios.

The scenarios from this file are merged with the scenarios from the document types (frameworks) *(on page 3420)*.

-v

This argument can be specified to activate verbose logging for DITA-OT and ANT scenarios. It is useful for debugging.

Tip:
For a GitHub use case sample of this script, see Oxygen Transformation Template.

Validate

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

All the validations possible in Oxygen XML Editor can also be performed from scripting. This includes validating various types of XML schemas, such as XSD, RNG, RNC, DTD, and NVDL, as well as JSON Schema, XProc, ANT, XSLT, XQuery, CSS, LESS, HTML, WSDL, OpenAPI, and of course, XML with XML schema, and JSON/YAML with JSON Schema.

The **Validate** script (`validate.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) can be used to validate a file or a directory and get the validation results in various formats.

Arguments for the Transform Script

```
sh scripts/validate.sh fileOrDirPath [-s schemaFilePath | -sn scenarioName] [-sf scenariosFilePath]
 [-if includeFilesFilter] [-ef excludeFilesFilter] [-ed excludeSubdirsFilter] [-rf reportFile]
 [-rft reportFormat] [-v] [-help | --help | -h | --h]
```

fileOrDirPath

Mandatory argument that specifies the path of the file or directory to validate (it can also be provided as a URL, but if you are validating directories, the only protocol considered is `'file://'`).

-s schemaFilePath

Optional argument that specifies the file path of the schema to validate against (it can also be provided as a URL).

-sn scenarioName

Optional argument that specifies the name of the validation scenario to be applied.

-sf scenariosFilePath

Optional argument that specifies the path of the file that stores the validation scenarios (either an **Oxygen** scenarios file or an **Oxygen** project file). It can also be provided as a URL.

Notes:

- The file that stores the validation scenarios must have a similar format to that generated from **Oxygen** by invoking **Export Global Validation Scenarios** from the **Options** menu. This type of **Oxygen**-generated scenarios files has a `.scenarios`

file extension by default and contains all the necessary information about custom validation scenarios created in **Oxygen**.

- **Oxygen** also saves the custom validation scenarios (as well as the scenario associations made explicitly for the files you work with) in special formatted **Oxygen** project files (usually with the `.xpr` file extension). Therefore, by using the arguments provided through **-sn** and **-sf** options, you can apply any scenario that was previously stored in either a scenarios file or an **Oxygen** project file.
- The **-s** and **-sn** options are mutually exclusive. Specifying both in the same command line is not allowed.

-if includeFilesFilter

Use this argument to only validate the files that match the specified pattern (e.g. `.xml,.json`). The default value is `*`.

-ef excludeFilesFilter

Excludes the files that match the specified pattern (e.g. `test.wsdl,draft.xsl`) from the validation.

-ed excludeSubdirsFilter

Excludes the sub-directories that match the specified pattern (e.g. `.svn,_svn,.git`).

-rf reportFile

Specifies the path for the report file to save the validation results, instead of presenting them in the console. The content of the report file is formatted according to the **-rft** argument. The report file path can also be provided as a URL.

-rft reportFormat

Specifies the format of the validation report. Possible values: `txt`, `text`, `xml`, `json`, `html`, `htm`. Default values: `txt`, `text`.

-v

Prints additional information to the console (Verbose mode).

-help | --help | -h | --h

Displays help text.

Additional Notes:

- Avoid activating the Verbose mode (**-v** option) when opting to redirect the console (and the validation report implicitly) to a specific file. That is done using the **>** operator instead of the **-rf** option. The additional information provided through verbose mode is also saved to the report file, making it to be reported as invalid when inspected in specialized editors. However, that information is placed at the beginning of the report, as plain text. If removed, the report should become valid.

- If the validation uses the **Saxon** engine and you do not have a commercial license, then the script automatically uses the **Saxon Home Edtion** distribution that does not require a license. However, if the validation involves specific **Saxon Personal / Enterprise Edition** advanced features, then the validation report clearly signals that an appropriate **Saxon** license was not found. Placing a valid **Saxon** license file in the `lib` directory from the **Oxygen** installation folder solves the problem and the validation operation works as expected.

Examples of the Validate Script

Example 1: Validate a File by Applying a Custom Validation Scenario

```
sh scripts/validate.sh "workspace/xmlFolder/xmlFile.xml" -sn "xmlValScn"
 -sf "workspace/scn/valScn.scenarios"
```

This command implies validating `xmlFile.xml` by applying the validation scenario named **xmlValScn**, described in the `valScn.scenarios` file. If you want to apply more than one validation scenario, you can use the `-sn scenarioName` construct multiple times.

Example 2: Validate a Directory by Applying an Oxygen Default Validation Scenario

```
sh scripts/validate.sh "workspace/DITAFolder" -sn "DITA"
```

A scenario name is provided, but without specifying a scenarios file. This command implies validating all files from `DITAFolder` by applying the **Oxygen** default validation scenario named **DITA** (in accordance with the association made in the **Document Type Configuration Dialog Box** *(on page 147)*).

Example 3: Validate a File by Applying Associated Scenarios Stored in an Oxygen Project File

```
sh scripts/validate.sh "workspace/mainFolder/main.xml" -sf "worksapce/proj/proj-1.xpr"
```

A scenarios file is provided, but without specifying a scenario name. In this case, the argument provided through the **-sf** option is assumed to be an **Oxygen** project file and it is used to search for validation scenario associations made for the `main.xml` file. This command line implies that if validation scenario associations for `main.xml` are found in `proj-1.xpr`, then those scenarios are identified and applied. Otherwise, the validation first considers the schema associations declared in `main.xml` (if any), or default **Oxygen** validation scenarios are applied in accordance with the type of the file to validate (e.g. XML in this example).

Example 4: Directory Default Validation and Custom Formatted Report Saved to a Specific Location

```
sh scripts/validate.sh ../important/xmlFolder -rft html
 -rf "../important/reports/validation rep.html"
```

No validation scenario name, no scenario file, and no schema provided. This command line involves validating all files from the `xmlFolder`. Each file is validated against the schema(s) internally associated (if any). Otherwise, the default **Oxygen** validation scenarios for the

respective file type are applied. Also, the validation report is formatted in HTML and is saved to the `validation rep.html` file at the specified location.

Figure 840. Example of an HTML Validation Report

SUMMARY

5 files verified in total
3 files reported with validation problems
6 problems found on aggregate

FILES WITH VALIDATION PROBLEMS

D:\workspace\library\lib-dir-final\library.json (4 problems)

Description	#/books/0/authors/0/short_bio: expected maxLength: 200, actual: 250
Severity	Error
Engine name	JSON Validator
System ID	D:\workspace\library\lib-dir-final\library.json
Main validation file	D:\workspace\library\lib-dir-final\library.json
Schema	D:\workspace\library\test-dir\lib.jschema
Start location	line: 10, column: 21
End location	line: 10, column: 32

Description	#/books/1/genre: ["Prose","Fiction"] is not a valid value. Expected: [Prose, Drama, Science, Romance, Poetry]
Severity	Error
Engine name	JSON Validator
System ID	D:\workspace\library\lib-dir-final\library.json
Main validation file	D:\workspace\library\lib-dir-final\library.json
Schema	D:\workspace\library\test-dir\lib.jschema
Start location	line: 20, column: 13
End location	line: 20, column: 20

Resources

For more information about the validation script, see the following resources:

- Video: **Validating XML and JSON Using Oxygen Command Line Scripts**
- Webinar: **Validating XML and JSON Documents Using Oxygen Scripting**

Tip:
For some GitHub use case samples of this script, see Oxygen Validation Template and Oxygen Validation Action.

XML Refactoring

Attention:

- This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.
- To execute an XQuery refactoring operation using this script, in additional to the scripting commercial license, you are required to purchase a Saxon EE license.

The **XML Refactoring** script (`xmlRefactoring.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) can be used to execute XML refactoring operations *(on page 852)*. You can run a refactoring operation by specifying the operation id of the operation. If, in addition to the refactoring operations provided by Oxygen XML Editor in the `OXYGEN_INSTALL_DIR/refactoring` folder and in framework configurations, you want to run a custom refactoring operation, you have to specify the directory that contains it, using the `od` (operations directory) argument.

Arguments for the XML Refactoring Script

```
sh scripts/xmlRefactoring.sh  -id operationId -i inputFilesOrDirectories [-f filesFilter]
[-od operationsDirectory] [-p param1=value1...] [-v]
```

-id operationId

The ID of the refactoring operation to be executed.

-i inputFilesOrDirectories

A list of space-separated input files or directories that the refactoring operation is applied to.

-f filesFilter

Specifies a filter for the input files by using a file pattern. For example, to restrict the operation to only analyze build files, you could use `build*.xml` for the file pattern.

-od operationsDirectory

A directory that contains additional refactoring operations.

-p param1=value1...

A list of space-separated pairs of a parameter's name and value used by the refactoring operation.

-v

This argument can be specified to activate verbose logging.

DITA Translation Package Builder

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

The **DITA Translation Package Builder** (`translationPackageBuilder.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) script helps you to build a translation package for DITA files that can be sent to translators. You can also extract the changed files back into your project once you receive the package back from the translators.

This script requires the **DITA Translation Package Builder** add-on to be installed in the all platforms distribution of Oxygen XML Editor. To install it the add-on, follow these instructions:

1. Go on the **DITA Translation Package Builder** plugin **Releases** page and download the latest translation-package-builder-{version}-plugin.jar package.
2. Unzip it inside `{oxygenInstallDir}/plugins`.

   Note:
   Do not create any intermediate folders. Afterwards, the file system should look like this: `{oxygenInstallDir}/plugins/translation-package-builder-{version}/plugin.xml`

Examples for the DITA Translation Package Builder Script

Example: Generating a Milestone File

```
sh scripts/translationPackageBuilder.sh -gm -i ditamapFile [-m milestoneFile] [-verbose]
```

This action is the first one to use. It will generate a unique hash for each documentation resource. This information will be used by the second action to detect which files have been modified. A milestone file should be generated the first time you install this plugin and henceforth, after each package is sent to translators.

-gm

Requests the generation of a milestone file.

-i ditamapFile

The main DITA map file.

-m milestoneFile

The path to the milestone file. If missing, it is assumed that the milestone will be saved in the DITA map parent folder with the following name: `{ditamapName}_translation_milestone.xml`.

-verbose

Generates a console log about the performed steps. It is useful for debugging.

Example: Creating a Package with the Modified Files to Send to Translation

```
sh scripts/translationPackageBuilder.sh  -gp -i ditamapFile [-m milestoneFile] -p package.zip
 [-verbose]
```

This action detects which files have been changed since the last generated milestone. These files are packed inside a ZIP file that can be sent to translators. After doing this, you can also generate a new milestone so that the next package will only contain new changes.

-gp

Requests the generation of a package with the modified files.

-i ditamapFile

The main DITA map file.

-m milestoneFile

The path to the milestone file. If missing, it is assumed that the milestone will be located in the DITA map parent folder with the following name: `{ditamapName}_translation_milestone.xml`.

-p package.zip

The path to the zip archive where all the modified files are collected.

-verbose

Generates a console log about the performed steps. It is useful for debugging.

Example: Applying a Translation Package Over a DITA Map

```
sh scripts/translationPackageBuilder.sh -ap -i ditamapFile -p package.zip [-verbose]
```

When the translated files arrive from the translator, you should open the DITA map that corresponds to the received language (e.g. open **dita-map-french.ditamap** if the package contains the french translation). Invoking this action will extract the changed files inside the map's directory.

-ap

Requests the application of a translation package over a DITA map.

-i ditamapFile

The main DITA map file that matches the received package language. For example, if the package contains topics translated into French, then this map is the French version of your DITA map.

-p package.zip

The path to the archive with all the translated files.

-verbose

Generates a console log about the performed steps. It is useful for debugging.

Batch Converter

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

The **Batch Converter** script (`batchConverter.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) helps you to convert between the following formats:

- HTML to XHTML
- HTML to DITA
- HTML to DocBook4 / DocBook5
- Markdown to XHTML
- Markdown to DITA
- Markdown to DocBook4 / DocBook5
- Word to XHTML
- Word to DITA
- Word to DocBook4 / DocBook5
- Excel to DITA
- Confluence to DITA
- DocBook to DITA
- OpenAPI to DITA
- JSON to XML
- JSON to YAML
- XML to JSON
- YAML to JSON

This script requires the **Oxygen Batch Documents Converter** add-on to be installed in the all platforms distribution of an **Enterprise** edition of Oxygen XML Editor.

To install the add-on, follow these instructions:

1. Go on the **Oxygen Batch Documents Converter** plugin **Releases** page and download the latest oxygen-batch-converter-{version}-plugin.jar package.
2. Unzip it inside `{oxygenInstallDir}/plugins`.

Note:
Do not create any intermediate folders. Afterwards, the file system should look like this:
`{oxygenInstallDir}/plugins/oxygen-batch-converter-{version}/plugin.xml`

Arguments for the Batch Converter Script

```
sh scripts/batchConverter.sh -i inputFiles -if inputFormat -o outputDirectory
-of outputFormat [-ss (true|false)] [-csd (true|false)] [-cs converterSettingsFile]
```

-i inputFiles

A list of space-separated input files or directories in file syntax form.

-if inputFormat

The format of the input files. The possible values are: **html**, **markdown**, **word**, **confluence**, **docbook**, **excel**, **openapi**, **json**, **yaml**, or **xml**.

-o outputDirectory

The output directory in file syntax form.

-of outputFormat

The format of the output files. The possible values are: **xhtml**, **dita**, **docbook4**, **docbook5**, **json**, **yaml**, or **xml**.

-ss (true|false) [only for Word to DITA, HTML to DITA, Markdown to DITA, DocBook to DITA, and OpenAPI to DITA conversions]

Splits sections marked by titles or headings to separate files and create a DITA map. The possible values are **true** or **false** (default).

-csd (true|false) [only for Markdown to DITA conversions]

Creates short description elements from the first paragraph before the headings. Possible values are **true** or **false** (default).

-cs converterSettingsFile

A file that contains the Batch Documents Converter add-on preferences settings. It can be an xpr file that contains project options or an xml file that contains global options. If not specified, the operation uses the application's default settings.

Confluence to DITA

The **Confluence to DITA** conversion processes the HTML content generated by the Confluence export process. For exporting, login to your Confluence account and navigate to the specific space that you want to export. Go to **Space Settings > Export space** and choose to export it as HTML. The `index.html` file resulting from this process has to be provided in the **inputFiles** argument.

Compile Framework Script

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor.

A custom *framework (on page 3420)* (document type) can be created using a special XML descriptor file *(on page 2249)*, either from scratch or by extending an existing built-in framework (such as DITA or DocBook) and then making modifications to it.

The **Compile Framework Script** (`compileFrameworkScript.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) helps you to compile the script into the `*.framework` file that represents the framework configuration. Although Oxygen XML Editor is now able to automatically compile and load scripts, you might want to compile it yourself to obtain the resulting `*.framework` file if your framework runs on a different version of Oxygen XML Editor.

Arguments for the Compile Framework Script

```
sh scripts/compileFrameworkScript.sh -i "script1.exf" "script2.exf" "frameworksDir"
```

-i inputFiles

A list of space-separated Framework Extension Script Files *(on page 2251)* (*.exf) or directories in file syntax form. If a directory is specified, the Framework Extension Script Files *(on page 2251)* are searched for inside it and in its child directories.

XSLT Stylesheets Documentation

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

You can generate documentation for XSLT Stylesheets from Oxygen XML Editor by using the **Tools > Generate Documentation > XSLT Stylesheet Documentation** main menu action. The settings dialog box has an **Export settings** option that can be used to export the settings to an XML configuration file. Once the settings are exported, you can use the `stylesheetDocumentation.sh` script (found in the `scripts` subfolder inside **Oxygen's** installation directory) to generate XSLT stylesheets documentation from the command line.

Sample Command-Line Arguments for the Generate XSLT Stylesheet Documentation Script

```
sh scripts/stylesheetDocumentation.sh xslFile [-cfg:configFile] | [-out:outputFile]
```

Tip:
For some GitHub use case samples of this script, see Oxygen Documentation Template and Oxygen Documentation Action.

XML Schema Documentation

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

You can generate documentation for XML Schemas from Oxygen XML Editor by using the **Tools > Generate Documentation > XML Schema Documentation** main menu action. The settings dialog box has an **Export settings** option that can be used to export the settings to an XML configuration file. Once the settings are exported, you can use the `schemaDocumentation.sh` script (found in the `scripts` subfolder inside **Oxygen's** installation directory) to generate XML Schema documentation from the command line.

Sample Command-Line Arguments for the Generate XML Schema Documentation Script

```
sh scripts/schemaDocumentation.sh  schemaFile [-cfg:configFile] [-out:outputFile]
[-format:<value>] [-xsl:xslFile] [-split:<value>] [-openInBrowser:<value>]
```

Tip:
For some GitHub use case samples of this script, see Oxygen Documentation Template and Oxygen Documentation Action.

JSON Schema Documentation

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

You can generate documentation for a JSON Schema file from Oxygen XML Editor by using the **Tools > Generate Documentation > JSON Schema Documentation** main menu action. This tool requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor presents a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **JSON Schema Documentation** action will invoke the tool.

You can use the `jsonSchemaDocGen.sh` script (found in the `scripts` subfolder inside **Oxygen's** installation directory) to generate documentation from a JSON schema file using the command line.

Tip:
For some GitHub use-case samples for this script, see Oxygen Documentation Template and Oxygen Documentation Action.

Arguments for the JSON Schema Documentation Script

```
sh scripts/jsonSchemaDocGen.sh filePath [-ofp outputFilePath] [-sb split by (location, components)]
 [-ea exclude annotations] [-ec exclude constraints] [-ep exclude properties] [-epp exclude pattern
 properties] [-ee exclude enumerations] [-es exclude source] [-eub exclude used by] [-ecp exclude
 compositions] [-ed exclude diagram] [-eim exclude image map] [-il include location] [-help |
 --help | -h | --h]
```

filePath

Mandatory argument specifying the path of the file that needs to generate documentation (it can also be provided as a URL).

-ofp output file path

Optional argument that specifies the path of the output file.

-sb split by (location, components)

Optional argument that specifies what type of split scenario is used (location, components). By default, one file scenario is used.

-ea exclude annotations

Optional argument that specifies if the JSON schema annotations should be present. Default value is true.

-ec exclude constraints

Optional argument that specifies if the JSON schema constraints should be present. Default value is true.

-ep exclude properties

Optional argument that specifies if the JSON schema properties should be present. Default value is true.

-epp exclude pattern properties

Optional argument that specifies if the JSON schema pattern properties should be present. Default value is true.

-ee exclude enumerations

Optional argument that specifies if the JSON schema enumerations should be present. Default value is true.

-es exclude source

Optional argument that specifies if the JSON schema source should be present. Default value is true.

-eub exclude used by

Optional argument that specifies if the JSON schema *used by* should be present. Default value is true.

-ecp exclude compositions

Optional argument that specifies if the JSON schema compositions should be present. Default value is true.

-ed exclude diagram

Optional argument that specifies if the JSON schema diagram should be present. Default value is true.

-eim exclude image map

Optional argument that specifies if the JSON schema image map should be present. Default value is true.

-il include location

Optional argument that specifies if the JSON schema location should be present. Default value is false.

-help | --help | -h | --h

Displays help text.

OpenAPI Documentation

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

You can generate documentation for an OpenAPI file from Oxygen XML Editor by using the **Tools > Generate Documentation > OpenAPI Documentation** main menu action. This tool requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor presents a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **OpenAPI Documentation** action will invoke the tool.

You can use the `openApiDocGen.sh` script (found in the `scripts` subfolder inside **Oxygen's** installation directory) to generate documentation from an OpenAPI file using the command line.

Tip:
For some GitHub use case samples of this script, see Oxygen Documentation Template and Oxygen Documentation Action.

Arguments for the OpenAPI Documentation Script

```
sh scripts/openApiDocGen.sh filePath [-ofp outputFilePath] [-sb split by (location, components)]
 [-ea exclude annotations] [-ec exclude constraints] [-ep exclude properties] [-epp exclude pattern
 properties] [-ee exclude enumerations] [-es exclude source] [-eub exclude used by] [-ecp exclude
 compositions] [-ed exclude diagram] [-eim exclude image map] [-il include location] [-help |
 --help | -h | --h]
```

filePath

Mandatory argument specifying the path of the file that needs to generate documentation (it can also be provided as a URL).

-ofp output file path

Optional argument that specifies the path of the output file.

-sb split by (location, components)

Optional argument that specifies what type of split scenario is used (location, components). By default, one file scenario is used.

-ea exclude annotations

Optional argument that specifies if the JSON schema annotations should be present. Default value is true.

-ec exclude constraints

Optional argument that specifies if the JSON schema constraints should be present. Default value is true.

-ep exclude properties

Optional argument that specifies if the JSON schema properties should be present. Default value is true.

-epp exclude pattern properties

Optional argument that specifies if the JSON schema pattern properties should be present. Default value is true.

-ee exclude enumerations

Optional argument that specifies if the JSON schema enumerations should be present. Default value is true.

-es exclude source

Optional argument that specifies if the JSON schema source should be present. Default value is true.

-eub exclude used by

Optional argument that specifies if the JSON schema *used by* should be present. Default value is true.

-ecp exclude compositions

Optional argument that specifies if the JSON schema compositions should be present. Default value is true.

-ed exclude diagram

Optional argument that specifies if the JSON schema diagram should be present. Default value is true.

-eim exclude image map

Optional argument that specifies if the JSON schema image map should be present. Default value is true.

-il include location

Optional argument that specifies if the JSON schema location should be present. Default value is false.

-help | --help | -h | --h

Displays help text.

WSDL Documentation (Deprecated)

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

You can generate documentation for WSDL documents from Oxygen XML Editor by using the **Tools > Generate Documentation > WSDL Documentation** main menu action. The settings dialog box has an **Export settings** option that can be used to export the settings to an XML configuration file. Once the settings are exported, you can use the `wsdlDocumentation.sh` script (found in the `scripts` subfolder inside **Oxygen's** installation directory) to generate XML Schema documentation from the command line.

Sample Command-Line Arguments for the Generate WSDL Documentation Script

```
sh scripts/wsdlDocumentation.sh wsdlFile [-cfg:configFile] | [-out:outputFile]
```

Tip:
For some GitHub use case samples of this script, see Oxygen Documentation Template and Oxygen Documentation Action.

XML Instance Generator

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

You can generate multiple XML documents from an XML Schema from Oxygen XML Editor by using the **Tools > Generate Sample XML Files** main menu action. The settings dialog box has an **Export settings** option that can be used to export the settings to an XML configuration file. Once the settings are exported, you can use the `xmlGenerator.sh` script (found in the `scripts` subfolder inside **Oxygen's** installation directory) to generate multiple XML instance files from the command line.

Sample Command-Line Arguments for the Generate Sample XML Files Script

```
sh scripts/xmlGenerator.sh path/to/config/file [-verbose]
```

Extended Version of the Script and its Arguments

```
sh scripts/xmlGenerator.sh [[path_to_config_file] [-s XML_schema_path -r root [-n ns] [-o
 output_dir]
[-f instance_name] [-i num_of_instances]] [-verbose]]
```

path_to_config_file

The path to the file that contains the configuration to be used.

-s XML_schema_path

The path to the XML schema to be used for generating the XML file(s). This argument can also be provided as a URL.

-n ns

The namespace used for the XML namespace declaration.

-r root

The root element for the generated file(s).

-o output_dir

The output directory to be used for storing the generated file(s).

-f instance_name

The pattern name to be used for the generated file(s). It is usually the name plus extension.

-i num_of_instances

The number of XML files to be generated.

-verbose

This argument can be specified to activate verbose logging.

Note:
Any value specified by the **-s**, **-n**, **-r**, **-o**, **-f**, or **-i** arguments overrides the corresponding value from the configuration file, if that file is specified in the **path_to_config_file** argument.

Flatten XML Schema

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

You can flatten an XML schema that contains multiple includes and redefines to a single schema file from Oxygen XML Editor by using the **Tools > Flatten Schema** main menu action. You can use the equivalent `flattenSchema.sh` script (found in the `scripts` subfolder inside **Oxygen's** installation directory) to flatten an XML schema from the command line.

Sample Command-Line Arguments for the Flatten Schema Script

```
sh scripts/flattenSchema.sh [-in:inputSchemaURL -outDir:outputDirectory
              [-flattenImports:<boolean_value>]
              | [-useCatalogs:<boolean_value>]
              [-flattenCatalogResolvedImports:<boolean_value>] [-verbose]]
```

Compare Directories

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

The **Compare Directories** script (`compareDirs.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) can be used to compare two directories and get the comparison results in various formats.

Arguments for the Compare Directories Script

```
sh scripts/compareDirs.sh firstDirPath secondDirPath [[baseDirPath] [-if includeFilesFilter]
 [-ia includeArchives] [-ef excludeFilesFilter] [-ed excludeSubdirsFilter] [-cm comparisonMode]
 [-alg comparisonAlg] [-als algStrength] [-iws ignoreWS] [-ipi ignorePI] [-icm ignoreComments]
 [-idt ignoreDocType] [-itn ignoreText] [-ins ignoreNS] [-ind ignoreNSDecl] [-inp ignorePrefixes]
 [-iao ignoreAttrOrder] [-iee ignoreExpStateForEmptyElems] [-enx XPathExprToExcludeNodes] [-out
 outputFormat] [-outfile outputFile] [-merge mergeOperation] [-mergeout outputDirPathForMerge]]
 [-help | --help | -h | --h]
```

firstDirPath

Mandatory argument that specifies the first directory path (it can also be provided as a URL using `'file://'` protocol).

secondDirPath

Mandatory argument that specifies the second directory path (it can also be provided as a URL using `'file://'` protocol).

baseDirPath

Optional argument that specifies the path of the base directory that the other two directories will be compared against in a 3-way comparison (it can also be provided as a URL). If present, it must appear immediately after the first two mandatory arguments.

-if includeFilesFilter

Use this argument to only include files that match the specified pattern in the comparison (e.g. `.xml`, `.json`). Default value = ***.

-ia includeArchives

If set to **true**, files from archives are included in the comparison. Default value = **false**.

-ef excludeFilesFilter

Use this argument to exclude files that match the specified pattern from the comparison (e.g. `*.jpg`).

-ed excludeSubdirsFilter

Use this argument to exclude sub-directories that match the specified pattern from the comparison (e.g. `.svn`, `_svn`, `.git`).

-cm comparisonMode

Specifies the comparison mode. There are three modes available: **content**, **binary**, and **timestamp**. Default value = **content**.

-alg comparisonAlg

Specifies the algorithm to be used for the comparison. Possible values: **auto**, **chars**, **words**, **lines**, **syntax_aware**, **xml_fast**, and **xml_accurate**. Default value = **auto**.

-als algStrength

Specifies the strength of the algorithm to be used for the comparison. Possible values: **low**, **medium**, **high**, and **very_high**. Default value = **medium**.

-iws ignoreWS

If set to **true**, whitespaces are ignored if differences consist only of whitespaces. Default value = **false**.

-ipi ignorePI (only for the XML-aware algorithms)

If set to **true**, processing instructions are ignored in the comparison. Default value = **false**.

-icm ignoreComments (only for the XML-aware algorithms)

If set to **true**, comments are ignored in the comparison. Default value = **false**.

-idt ignoreDocType (only for the XML-aware algorithms)

If set to **true**, DOCTYPE sections are ignored in the comparison. Default value = **false**.

-itn ignoreText (only for the XML-aware algorithms)

If set to **true**, text content is ignored in the comparison. Default value = **false**.

-ins ignoreNS (only for the XML-aware algorithms)

If set to **true**, namespaces are ignored in the comparison. Default value = **false**.

-ind ignoreNSDecl (only for the XML-aware algorithms)

If set to **true**, namespace declarations are ignored in the comparison. Default value = **false**.

-inp ignorePrefixes (only for the XML-aware algorithms)

If set to **true**, prefixes are ignored in the comparison. Default value = **false**.

-iao ignoreAttrOrder (only for the XML-aware algorithms)

If set to **true**, the order of attributes is ignored in the comparison. Default value = **false**.

-iee ignoreExpStateForEmptyElems (only for the XML-aware algorithms)

If set to **true**, the expansion state for empty elements is ignored in the comparison. Default value = **false**.

-enx XPathExprToExcludeNodes

Specifies an XPath expression to exclude certain nodes from the comparison.

Note:

The argument is only considered if you specify either `html/ifcr` or `htm/ifcr` as an option for the **-out** argument. These are the only script options that involve additional file comparisons, where exclusion of certain nodes from the comparison via XPath expressions can be applied.

-merge mergeOperation

If set to **true**, a merge operation is invoked after the comparison. Default value = **false**.

Notes:

- This argument is considered only for 3-way comparisons (i.e. only if the `baseDirPath` argument is provided).
- The merge operation is similar to the same process in any versioning system. Following the comparison between the first and second directories (relative to the base folder), all the differences of the type **incoming** are considered and the content of the first directory is updated accordingly.

- Conflicting changes are not addressed.
- After the comparison, a report is created that provides details about the changes that were made.

-mergeout outputDirPathForMerge

Invokes a merge operation after the comparison and also allows you to specify the output directory path for the merge operation. For example, it allows you to specify a specific existing or new directory where the results of the merge operation is saved, other than the first directory path for the comparison (which is what happens when using only the `-merge` argument). The path of the directory can also be provided as a URL using `file://` protocol. This argument and the `-merge` argument are not dependent on each other.

-out outputFormat

Specifies the format of the output. Possible values: **yaml/grouped**, **yaml/raw**, **json/grouped**, **json/raw**, **xml/grouped**, **xml/raw**, **html**, **html/ifcr**, **htm**, or **htm/ifcr**. Default value = **yaml/grouped**.

Notes:

- If you choose to save/redirect the console output to a file, this argument establishes the type of the output file and its content is formatted accordingly. If you skip specifying the "**/grouped**" or the "**/raw**" qualifiers, "**/grouped**" takes precedence.
- If you choose the **html** or **htm** output format, it is recommended that you also choose to save/redirect the console to the specified HTML file to view the comparison result in your preferred browser.
- The "**/ifcr**" qualifier for the **html** or **htm** values is considered only if the `-outfile` argument is also present. *IFCR* is an acronym for *Include File Comparison Reports* and it means that, along with generating the directory comparison report, separate file comparison reports will be generated for all modified file pairs. These reports are available through links from the main report and are saved to a specific directory based on the value provided by the `outfile` argument. It will have the same parent directory and the same name as the **outputFile** plus *-OXY-FC-REPORTS* added to the end of its name.
- The **html** value, as well as the **grouped**, **raw**, or **ifcr** qualifiers, are not considered if the `-merge` argument is present.

-outfile outputFile

Specifies the path for an output file to save the comparison results, instead of presenting them in the console. The content of the output file is formatted according to the `-out` argument. The output file path can also be provided as a URL using `file://` protocol.

-help | --help | -h | --h

Displays help text.

Notes:

- For boolean arguments, it is not necessary to provide the "true" value. Their presence in the argument list is equivalent to setting their value to "true" (and their absence from the argument list is equivalent to setting their value to "false"). However, constructs of the form `bool_option true|false` are accepted and interpreted accordingly.
- File markers used in reports are as follows: M = modified, O1 = only found in 1st directory, O2 = only found in 2nd directory.

Examples of Compare Directories Script

Example 1: Compare Directories and Include Archives While Excluding JPEGs

The following command results in archives being included in the comparison, while JPEGs are excluded:

```
sh scripts/compareDirs.sh dir1 dir2 -ia true -ef *.jpg
```

Example 2: Compare Directories Only Including XML Files While Excluding Comments and the Attribute Order

The following command only includes XML files (even from archives) in the comparison, while ignoring the comments and attribute order:

```
sh scripts/compareDirs.sh dir1 dir2 -if *.xml -ia -iao -icm
```

Example 3: Compare Directories Only Including XML Files While Excluding Comments and the Attribute Order

The following command redirects the comparison results to a JSON file named "**results.json**", with "**raw**" mode formatting:

```
sh scripts/compareDirs.sh dir1 dir2 -out json/raw > results.json
```

Example 4: Compare Directories and Generate Comparison Report

It is possible to generate a report in the form of an HTML file that contains the results of the comparison. The following command compares the directories and redirects the console to the specified HTML file to view the comparison results:

```
sh scripts/compareDirs.sh dir1 dir2 -out html -outfile results.html
```

Compare Files Script *(on page 3406)*

Compare Files

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

The **Compare Files** script (`compareFiles.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) can be used to compare files (2-way or 3-way) and get the comparison results in various formats.

Arguments for the Compare Files Script

```
sh scripts/compareFiles.sh firstFilePath secondFilePath [[baseFilePath] [-ct contentType]
 [-alg comparisonAlg] [-als algStrength] [-iws ignoreWS] [-ipi ignorePI] [-icm ignoreComments]
```

```
[-icd ignoreCDATA] [-idt ignoreDocType] [-itn ignoreText] [-ins ignoreNS] [-ind ignoreNSDecl]
[-inp ignorePrefixes] [-iao ignoreAttrOrder] [-iee ignoreExpStateForEmptyElems] [-enx
XPathExprToExcludeNodes] [-out outputFormat]] [-help | --help | -h | --h]
```

firstFilePath

Mandatory argument that specifies the first file path (it can also be provided as a URL).

secondFilePath

Mandatory argument that specifies the second file path (it can also be provided as a URL).

baseFilePath

Optional argument that specifies the path of the base file that the other two files will be compared against in a 3-way comparison (it can also be provided as a URL).

-ct contentType

Specifies the content type of the files to be compared. Possible values (based on known extensions of some of the most common file types): `.xml`, `.dtd`, `.css`, `.rnc`, `.xquery`, `.json`, `.yaml`, `.java`, `.js`, `.c`, `.cpp`, `.pl`, `.py`, `.php`, `.sql`, `.bat`, `.sh`, `.properties`, `.txt`. The option is used to force the file handling to the specific type of file. Otherwise, the file extension is auto-detected.

-alg comparisonAlg

Specifies the algorithm to be used for the comparison. Possible values: **auto**, **chars**, **words**, **lines**, **syntax_aware**, **xml_fast**, and **xml_accurate**. Default value = **auto**.

-als algStrength

Specifies the strength of the algorithm to be used for the comparison. Possible values: **low**, **medium**, **high**, and **very_high**. Default value = **medium**.

-iws ignoreWS

If set to **true**, whitespaces are ignored if differences consist only of whitespaces. Default value = **false**.

-ipi ignorePI (only for the XML-aware algorithms)

If set to **true**, processing instructions are ignored in the comparison. Default value = **false**.

-icm ignoreComments (only for the XML-aware algorithms)

If set to **true**, comments are ignored in the comparison. Default value = **false**.

-idt ignoreDocType (only for the XML-aware algorithms)

If set to **true**, DOCTYPE sections are ignored in the comparison. Default value = **false**.

-itn ignoreText (only for the XML-aware algorithms)

If set to **true**, text content is ignored in the comparison. Default value = **false**.

-ins ignoreNS (only for the XML-aware algorithms)

If set to **true**, namespaces are ignored in the comparison. Default value = **false**.

-ind ignoreNSDecl (only for the XML-aware algorithms)

If set to **true**, namespace declarations are ignored in the comparison. Default value = **false**.

-inp ignorePrefixes (only for the XML-aware algorithms)

If set to **true**, prefixes are ignored in the comparison. Default value = **false**.

-iao ignoreAttrOrder (only for the XML-aware algorithms)

If set to **true**, the order of attributes is ignored in the comparison. Default value = **false**.

-iee ignoreExpStateForEmptyElems (only for the XML-aware algorithms)

If set to **true**, the expansion state for empty elements is ignored in the comparison. Default value = **false**.

-enx XPathExprToExcludeNodes

Specifies an XPath expression to exclude certain nodes from the comparison.

-merge mergeOperation

If set to **true**, a merge operation is invoked after the comparison. Default value = **false**.

Notes:

- This argument is considered only for 3-way comparisons (i.e. only if the `baseFilePath` argument is provided).
- The merge operation is similar to the same process in any versioning system. Following the comparison between the first and second files (relative to the base file), all the differences of the type **incoming** are considered and the content of the first file is updated accordingly.
- If conflicting changes are detected, the merge operation is aborted and the first file remains unchanged.
- After the comparison and merge, a report is created that provides some details about the changes that were made.

-mergeout outputDirPathForMerge

Invokes a merge operation after the comparison and also allows you to specify the output directory path for the merged file. Instead of directly affecting the first compared file (which is what happens when using only the `-merge` argument), a new file is created with the same name as the first file and it is saved in the specified directory. The path of the output directory can also be provided as a URL. This argument and the `-merge` argument are not dependent on each other.

-out outputFormat

Specifies the format of the output. Possible values: **yaml**, **json**, **xml**, **html**, **htm**, **html/inlineCSS**, or **htm/inlineCSS**. Default value = **yaml**.

Notes:

- If you choose to save/redirect the console output to a file, this argument establishes the type of the output file and its content is formatted accordingly.
- If you choose any of the **html**, **html/inlineCSS**, **htm**, or **htm/inlineCSS** output formats, it is recommended that you also choose to save/redirect the console to the specified HTML file to view the comparison result in your preferred browser.
- The **inlineCSS** qualifier for the **html** and **htm** values implies that the CSS-based generated HTML code is more suitable to be directly inserted in emails (as most email clients only accept inline CSS styling for HTML emails.
- The **html** and **htm** values (with or without the **inlineCSS** qualifier) are not considered if the `-merge` argument is present.

-outfile outputFile

Specifies the path for an output file to save the comparison results, instead of presenting them in the console. The content of the output file is formatted according to the `-out` argument. The output file path can also be provided as a URL.

-help | --help | -h | --h

Displays help text.

Note:
For boolean arguments, it is not necessary to provide the "true" value. Their presence in the argument list is equivalent to setting their value to "true" (and their absence from the argument list is equivalent to setting their value to "false"). However, constructs of the form `bool_option true|false` are accepted and interpreted accordingly

Examples of Compare Files Script

Example 1: Compare Files and View Results in XML Format

The following command compares the files (ignoring the namespaces and prefixes) and redirects the console output to the `results.xml` file (XML-formatted):

```
sh scripts/compareFiles file1 file2 -ins -inp -ind -out xml > results.xml
```

Example 2: Compare Files with Line by Line Algorithm

The following command compares the files using the **lines** algorithm and ignores whitespaces:

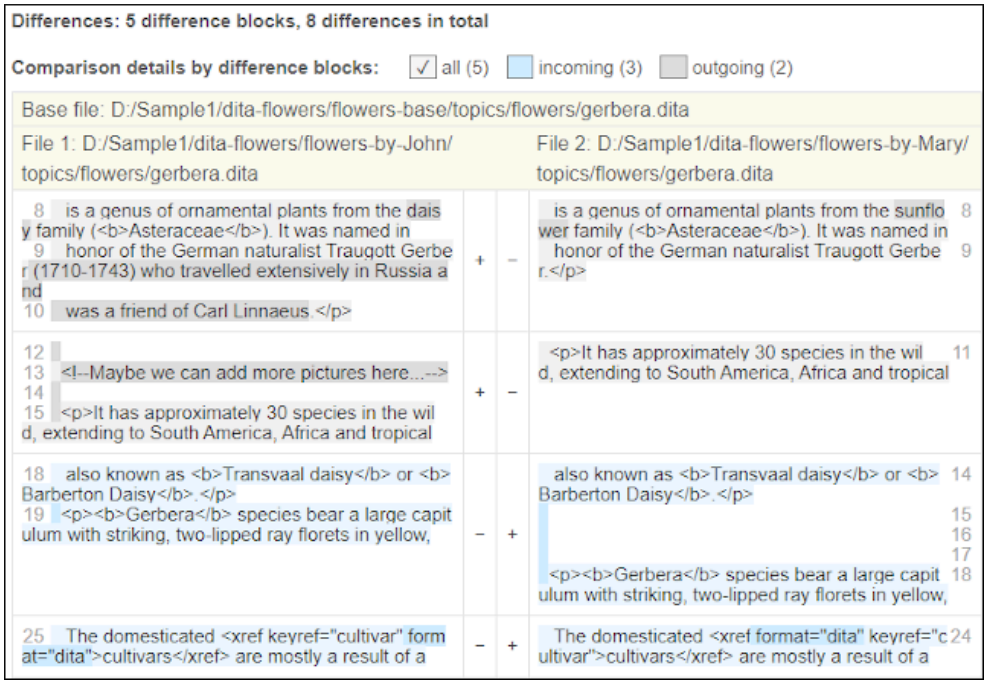
```
sh scripts/compareFiles.sh file1 file2 -alg lines -iws
```

Example 3: Compare Files and Generate Comparison Report

It is possible to generate a report in the form of an HTML file that contains the results of the comparison. The following command compares the files and redirects the console to the specified HTML file to view the comparison results:

```
sh scripts/compareFiles.sh file1 file2 -out html -outfile outFileName.html
```

Figure 842. Example of File Comparison Report in HTML Format



Resources

For more information about the file comparison script and how to generate comparison reports in various formats, see the following resources:

- Webinar: **The New Oxygen Compare and Merge Scripts**.
- Video: **Generating File Comparison Reports Using Command-Line Scripts**.

Related information

Compare Directories Script *(on page 3401)*

Merge Files with Change Tracking Highlights

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

The **Merge Files with Change Tracking Highlights** script (`mergeFilesTrackChanges.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) can be used to merge 2 XML files (based on a 2-way

comparison). The **Author** mode comparison results are saved as documents with highlighted tracked changes that can later be reviewed and accepted or rejected.

Notice:
This script is intended to be used for merging XML documents (Oxygen XML Editor creates change tracking markers only for XML file types. Using this script for document types other than XML, or for documents that are not XML well-formed, causes document parsing errors and the merge operation fails.

Arguments for the Merge Files with Change Tracking Highlights Script

```
sh mergeFilesTrackChanges.sh pathOfBaseFile pathOfFileToMergeWith [[pathOfOutFile] [-nb
 noBackupOfBaseFile]] [-help | --help | -h | --h]
```

pathOfBaseFile

Mandatory argument that specifies the path of the base file (it can also be provided as a URL).

pathOfFileToMergeWith

Mandatory argument that specifies the file to merge with (it can also be provided as a URL).

pathOfOutFile

Optional argument that specifies the path of the file where the merge operation results are saved to (it can also be provided as a URL). If present, it must appear immediately after the first two mandatory arguments. If absent, the merge results are saved to the base file, by overwriting it. You cannot choose the same file specified as the file to merge with as the output file (the merge process is aborted in this case). Also, if the output is a remote resource, its entire parent directory structure must already exist. Otherwise, an I/O exception is thrown and the merge results cannot be saved.

-nb noBackupOfBaseFile

Set to **true** if you do not want a backup copy of the base file on the hard disk. There are 2 situations when a backup of the base file is performed automatically and the backup operation must succeed to proceed with the merge. Otherwise, the merge process is aborted if the output file is not specified (i.e. the `pathOfOutFile` argument is not present) or the specified output file is the base file itself.

The backup copy will have the same parent directory as the base directory and its name will be the name of the base file suffixed by ".OXY.BAK". The default value is **false**, which means that for either of the 2 previously mentioned situations, a backup copy of the base file will be kept on the hard disk.

> **Note:**
> The backup copy can be deleted only if the base file and, implicitly, its backup copy are local resources (not remote).

-help | --help | -h | --h

Displays help text.

> **Note:**
> For boolean arguments, it is not necessary to provide the "true" value. Their presence in the argument list is equivalent to setting their value to "true" (and their absence from the argument list is equivalent to setting their value to "false"). However, constructs of the form `bool_option true|false` are accepted and interpreted accordingly

Examples of Compare Files Script

Example 1: Compare Files and View Results in XML Format

The following command results in merging `file1` and `file2` into `outfile` with changes highlighted:

```
sh scripts/mergeFilesTrackChanges.sh file1 file2 outfile
```

Example 2: Compare Files with Line by Line Algorithm

The following command results in merging `file1` and `file2` by overwriting `file1`. However, the `file1` is backed up first:

```
sh scripts/mergeFilesTrackChanges.sh file1 file2
```

Example 3: Compare Files and Generate Comparison Report

The following command results in merging `file1` and `file2` by overwriting `file1`. Although `file1` is initially backed up, the backup is eventually removed:

```
sh scripts/mergeFilesTrackChanges.sh file1 file2 -nb
```

Merge Directories with Change Tracking Highlights

> **Attention:**
> This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

The **Merge Directories with Change Tracking Highlights** script (`mergeDirsTrackChanges.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) can be used to merge 2 directories (based on a 2-way comparison). All pairs of modified XML files involved in the process are merged by saving the **Author**

mode comparison results as documents with highlighted tracked changes that can be later reviewed and accepted or rejected.

Arguments for the Merge Directories with Change Tracking Highlights Script

```
sh mergeDirsTrackChanges.sh pathOfBaseDir pathOfDirToMergeWith [[pathOfOutDir] [-nb
 noBackupOfBaseDir] [-nu noUpdateOfModifNonXMLFiles] [-na noAddingFilesOnlyPresentInDirToMergeWith]
 [-nd noDeletionOfFilesOnlyPresentInBaseDir] [-cm createChangeTrackingMarkersForAddedXMLFiles]]
 [-help | --help | -h | --h]
```

pathOfBaseDir

Mandatory argument that specifies the path of the base directory (it can also be provided as a URL using `file://` protocol).

pathOfDirToMergeWith

Mandatory argument that specifies the path of the directory to merge with (it can also be provided as a URL using `file://` protocol).

pathOfOutDir

Optional argument that specifies the path of the directory where the merge operation results are saved to (it can also be provided as a URL using `file://` protocol). If present, it must appear immediately after the first two mandatory arguments. If absent, the merge results are saved to the base directory, by overwriting it. You cannot choose the same directory specified as the directory to merge with as the output directory (the merge process is aborted in this case).

-nb noBackupOfBaseDir

Set to **true** if you do not want a backup copy of the base directory on the hard disk. There are 2 situations when a backup of the base directory is performed automatically and the backup operation must succeed to proceed with the merge. Otherwise, the merge process is aborted if the output directory is not specified (i.e. the `pathOfOutDir` argument is not present) or the specified output directory is the base directory itself.

The backup copy will have the same parent directory as the base directory and its name will be the name of the base directory suffixed by ".OXY.BAK". The default value is **false**, which means that for either of the 2 previously mentioned situations, a backup copy of the base directory will be kept on the hard disk.

-nu noUpdateOfModifNonXMLFiles

Set to **true** if you want to keep the non-XML files at their versions from the base directory. The default value is **false**, which means that all files in the output directory that are copies of non-XML files in the base directory will be replaced by their corresponding files in the directory to merge with.

-na noAddingFilesOnlyPresentInDirToMergeWith

Set to **true** if you want to skip adding the files that are only present in the directory to merge with to the output directory as well. The default value is **false**, which means that all files that are only present in the directory to merge with are also added to the output directory.

-nd noDeletionOfFilesOnlyPresentInBaseDir

Set to **true** if you want to preserve the files that are only present in the base directory. The default value is **false**, which means that all files that are only present in the base directory and initially copied to the output directory are deleted.

-cm createChangeTrackingMarkersForAddedXMLFiles

Set to **true** if you want to create change tracking markers for the XML files only present in the directory to merge with (that will be added to the output directory). Although these files have no counterparts in the base directory, change tracking markers of the type "entire content added/inserted" will be created. The option is not necessarily intended for the merge process itself, but it might prove a useful addition when you want to apply various *Oxygen* transformation scenarios to the resulting output directory. For example, if you merge 2 versions of a DITA project and then want a PDF to highlight the changes between those versions, you can apply a transformation on the resulting `ditamap` file. The `-am` option presents the new DITA files as "added content" in the resulting PDF. Note that the option is only considered if the `-na` argument is absent or is explicitly set to **false** (default value).

-help | --help | -h | --h

Displays help text.

Notes:

- The merge process has a preliminary phase where the entire structure and content of the base directory is copied to the output directory.
- For boolean arguments, it is not necessary to provide the "true" value. Their presence in the argument list is equivalent to setting their value to "true" (and their absence from the argument list is equivalent to setting their value to "false"). However, constructs of the form `bool_option true|false` are accepted and interpreted accordingly.
- Once the merge operation is complete, a report file is created and saved in the output directory (in a separate subdirectory named ".__OXY__MERGE__REPORT"). Loading the report file in Oxygen XML Editor provides additional functionality. Aside from the fact that the report provides an overview of the merge process, it also provides links to all the files in the resulting output directory. You can use the respective links to load the XML files in the editor, then switch to **Author** mode to review the tracked changes and accept or reject them.

Examples of Compare Directories Script

Example 1: Compare Directories Without Updating non-XML Files

The following command results in merging `dir1` and `dir2` into `outdir`, but without updating the non-XML files in `dir1` detected with changes to their version in `dir2`:

```
sh scripts/mergeDirsTrackChanges.sh dir1 dir2 outdir -nu
```

Example 2: Compare Two Directories and Overwrite the First One

The following command results in merging `dir1` and `dir2` by overwriting `dir1`. However, the `dir1` is backed up first:

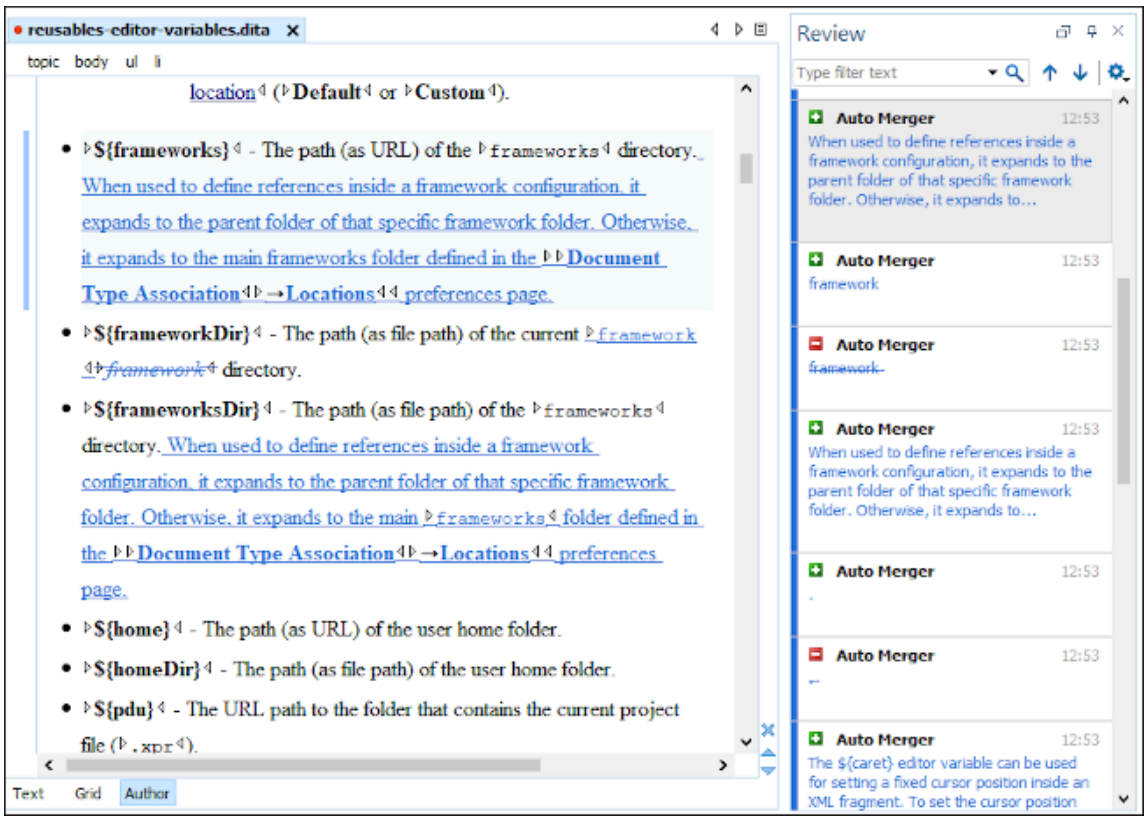
```
sh scripts/mergeDirsTrackChanges.sh dir1 dir2
```

Example 3: Compare Directories and Create Change Tracking Markers

The following command results in merging `dir1` and `dir2` into `outdir` and creating change tracking markers (of the type "entire content added/inserted") for all XML files that are only present in `dir2` (to be added to the `outdir`):

```
sh scripts/mergeDirsTrackChanges.sh dir1 dir2 outdir -cm
```

Figure 843. Example of a Merged File with Change Tracking Markers Opened in Author Mode



Format and Indent Files

Attention:
This script is bundled with the all platforms distribution of Oxygen XML Editor. To run the script, you are required to purchase a special scripting commercial license.

The **Format and Indent Files** script (`batchFormatAndIndent.bat`/`batchFormatAndIndent.sh`, found in the `scripts` subfolder inside **Oxygen's** installation directory) can be used to format and indent multiple files at once.

Arguments for the Format and Indent Files Script

```
batchFormatAndIndent -i inputFilesAndDirs [-f filesFilter] [-s formattingSettingsFile] [-r] [-ih]
 [-v]
```

-i inputFilesAndDirs

The input files and directories.

-f filesFilter

A filter for the input files, specified by using a file pattern (e.g. `*.xml`, `t_*.dita`).

-s formattingSettingsFile

A file that contains formatting settings. It can be an `.xpr` file that contains project options or an `.xml` file that contains global options. If not specified, the operation uses the application's default settings.

-r

Use this argument if the operation should be performed recursively for the specified input directories.

-ih

Use this argument if you want the operation to also format and indent hidden files.

-v

Activates verbose logging. It is useful for debugging purposes.

24.

Glossary

Active Cell

Active cell refers to the selected cell where data is entered when you begin typing. Only one cell is active at a time. The *active cell* is bounded by a heavy border.

Alternate CSS Style

The ***Alternate CSS Style*** refers to the choices in the bottom half of **Styles** drop-down menu (on the toolbar) that makes it easy to apply style changes to your documents as they appear in **Author** mode and the output without having to edit the CSS stylesheets. By default, the *alternate styles* are applied like layers, they are merged sequentially with the *main CSS style (on page 3421)*, and you can activate any number of them. However, if you deselect the **Enable multiple selection of alternate CSSs** option *(on page 154)* in the **CSS** subtab of the **Document Type** configuration dialog box *(on page 147)*, the *alternate styles* are treated like *main CSS styles (on page 3421)* and you can only select one at a time.

For more information, see Configuring and Managing Multiple CSS Styles for a Framework *(on page 2262)*.

Anchor

An ***Anchor*** is used in various types of links to take the user to a specific location within the target document. It is designated in a URL or in the value of the `@href` attribute with a # symbol followed by the anchor that is defined in a target ID (for example `href="MyTopic.dita#anchor`).

Apache Ant

Apache Ant (Another Neat Tool) is a software tool for automating software build processes.

Block Element

A ***block element*** is intended to be visually separated from its siblings, usually vertically. For instance, paragraphs and list items are *block elements*. It is distinct from a *inline element*, which has no such separation.

Bookmap

A ***bookmap*** is a specialized *DITA map* used for creating books. A *bookmap* supports book divisions such as chapters and book lists such as indexes.

Callout

A ***callout*** is a string of text inside a graphic and is connected to a specific location in a document by a line. Oxygen XML Editor uses callouts to present comments and other types of review modifications.

Canonicalize

To ***canonicalize*** something means to convert it to a standard format that everyone generally uses. When using the term with regard to XML, it refers to the process of converting data that has more than one possible representations into a standardization that conforms to the specification of an XML document or document subset. It is helpful for applications that require the ability to test whether or not the content of an XML document or subset has been changed.

Content Completion Assistant

The ***Content Completion Assistant*** refers to a very helpful mechanism in Oxygen XML Editor that offers a list of proposed items that could be inserted at the current location, depending on the current context, editing mode, and type of document. It also tries to determine the most logical choice in the current editing context and displays that proposal at the beginning of the list.

For more information about this feature and how to invoke it, depending on your editing context, see the following:

- Content Completion Assistant in Author Mode *(on page 626)*
- Content Completion Assistant in Text Mode *(on page 542)*
- Content Completion Assistant in Grid Mode *(on page 596)*
- Content Completion in XSLT Stylesheets *(on page 905)*
- Content Completion in Ant Build Files *(on page 950)*
- Content Completion in XML Schema *(on page 1004)*
- Content Completion in XQuery *(on page 1048)*
- Content Completion Assistance in WSDL Documents *(on page 1066)*
- Content Completion in CSS Stylesheets *(on page 1090)*
- Content Completion in LESS Stylesheets *(on page 1094)*
- Content Completion in Relax NG Schemas *(on page 1102)*
- Content Completion in NVDL Schemas *(on page 1118)*
- Content Completion in JavaScript Documents *(on page 1222)*
- Content Completion in Schematron Documents *(on page 1244)*
- Content Completion in SQF *(on page 1281)*

Dockable

A ***Dockable*** window is one that can be moved and resized, and either floated or pinned to a location, allowing you to configure the workspace according to your preferences.

Document Fragment

A ***document fragment*** represents a portion of an XML document's tree of nodes or content.

Document Type Association

In general terms, a ***Document Type Association*** is a set of rules that associate a document type with a *framework (on page 3420)*. In Oxygen XML Editor, ***Document Type Association*** also specifically refers to a preferences page *(on page 145)* where you can create new custom *frameworks* or edit existing ones. Note that *frameworks* (document types) that come built-in with Oxygen XML Editor are read-only, but you can **Extend** *(on page 146)* or **Duplicate** *(on page 146)* them to configure them as custom *frameworks*.

DITA Map

A ***DITA map*** is a component of the DITA *framework (on page 3420)* that provides the means for a hierarchical collection of DITA topics that can be processed to form an output. Maps do not contain the content of topics, but only references to them. These are known as topic references. Usually, the maps are saved on disk or in a CMS with the extension `.ditamap`.

Maps can also contain relationship tables that establish relationships between the topics contained within the map. Relationship tables are also used to generate links in your published document.

You can use your map or *bookmap (on page 3417)* to generate a deliverable using an output type such as XHTML, PDF, HTML Help, or Eclipse Help.

DITA Open Toolkit

DITA Open Toolkit is an open-source publishing engine for content authored in the Darwin Information Typing Architecture. It is a vendor-independent, open-source implementation of the DITA standard, released under the Apache License, Version 2.0.

The toolkit supports all versions of the OASIS DITA specification, including 1.0, 1.1, 1.2, and 1.3.

DITA-OT

Related information

http://www.dita-ot.org/

DITA-OT-DIR

DITA_OT_DIR refers to the default directory that is specified for your DITA Open Toolkit distribution in the **Options > Preferences > DITA** preferences page *(on page 277)*.

For example, if you are using DITA-OT 4.1.2 that comes bundled with Oxygen XML Editor, the default directory is: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/`*DITA-OT*. You can also specify a custom directory.

Foldable Element

A ***foldable element*** refers to elements that can be collapsed and expanded in Oxygen XML Editor. *Foldable elements* are marked with a small triangle (/) on the left side of the editor panel and you can use that triangle to quickly collapse or expand them. This feature is helpful when you are working with large documents and you want to temporarily hide blocks of content. You can right-click the triangle to access additional collapse and expand actions (**Collapse Other Folds**, **Collapse Child Folds**, **Expand Child Folds**, **Expand All**).

Framework

A ***framework*** refers to a package that contains resources and configuration information to provide ready-to-use support for a vocabulary or document type. A *framework* is associated to a document type according to a set of rules. It also includes a variety of settings that improve editing capabilities for its particular file type. Oxygen XML Editor includes a **Document Type Configuration Dialog Box** *(on page 147)* that allows you to define the set of rules and customize various authoring mechanisms for new or existing *frameworks*.

For advanced details about customizing your own *framework*, see the Creating and Configuring Custom Frameworks *(on page 2248)* section.

Global Options

Global Options refers to the storage option *(on page 320)* in the Oxygen XML Editor preference pages (**Options > Preferences**). If you select **Global Options** *(on page 321)*, the options in that particular preferences page are stored locally on your computer and are not accessible to other users (unless you export them into an XML options file *(on page 322)* that can then be shared).

IDML

IDML is an abbreviation for Adobe InDesign Markup files.

Inline Element

An ***inline element*** is intended to be displayed in the same line of text as its siblings or the surrounding text. For instance, strong and emphasis in HTML are *inline elements*. It is distinct from a *block element*, which is visually separated from its siblings.

Java Archive

Java Archive (JAR) is an archive file format. *JAR* files are built on the ZIP file format and have the `.jar` file extension. Computer users can create or extract *JAR* files using the `jar` command or an archive tool.

Key Space

The concept of a ***Key Space*** in DITA refers to a set of all possible keys that can be used in a *DITA map* structure. A ***Key Space*** is established when a *root map (on page 3424)* defines a set of effective key bindings. When Oxygen XML Editor processes key references, it determines the effective binding of a given key to a resource in the context of the specified *root map (on page 3090)*.

Keystore

A ***Keystore*** is an encrypted file that contains private keys and certificates. There are two types of *keystores* that are supported in Oxygen XML Editor:

- **Java Key Store (JKS)**
- **Public-Key Cryptography Standards version 12 (PKCS-12)**

Main CSS Style

The ***Main CSS Style*** refers to the selection in the top half of the **Styles** drop-down menu (on the toolbar) that makes it easy to quickly change the look of your documents as they appear in **Author** mode and the output without having to edit the CSS stylesheets. The *main CSS* applies to the whole document and you can also select one or more *alternate styles (on page 3417)* (listed in the bottom half of the drop-down menu) that behave like layers and are merged sequentially with the *main CSS style*.

For more information, see Configuring and Managing Multiple CSS Styles for a Framework *(on page 2262)*.

Main File

A ***Main File*** typically refers to the root of an imported or included tree of modules and this support helps you simplify the configuration and development of XML projects. For more information, see the Contextual Project Operations Using 'Main Files' Support *(on page 428)* section.

Oxygen Publishing Template

Oxygen Publishing Template defines all the aspects related with the **look and feel(layout and styles)** for the **WebHelp Responsive** output.

The template is self-contained and packed as a ZIP archive making it easy t share with others. It represents the main method for customizing the *WebHelp Responsive* output.

Related Information:
Publishing Template Package Contents for WebHelp Responsive Customizations *(on page 1661)*

Perspective

In Oxygen XML Editor, a ***perspective*** refers to an interface layout geared towards a specific editing environment. Each *perspective* includes a unique set of interface objects, toolbars, views, and features.

You can change the *perspective* by selecting the respective icon () in the top-right corner of Oxygen XML Editor or by selecting the *perspective* from the **Window > Open Perspective** menu.

The *perspectives* that are available in Oxygen XML Editor are:

- **Editor** *(on page 353)* - The most commonly used *perspective* and it is used to edit XML documents.
- **DITA** *(on page 355)* - Provides an editing environment with default side-views and other interface components that are optimal for working with DITA projects.
- **XSLT Debugger** *(on page 356)* - Used to detect problems in an XSLT transformation by executing the process step by step in a controlled environment.
- **XQuery Debugger** *(on page 358)* - Used to detect problems in an XQuery transformation process by executing the process step by step in a controlled environment
- **Database** *(on page 359)* - Used to browse and manage databases.

Plugin

In Oxygen XML Editor, a ***plugin*** is a component that adds extended functionality using a series of extension points and can be installed as an *add-on*. For more information, along with a full list of *add-ons* that are officially supported for Oxygen XML Editor, see Oxygen XML Add-on Repositories.

For more information, see the following topics:

- Installing and Updating Add-ons *(on page 126)*
- Automatic and Manual Methods for Installing Plugins *(on page 2533)*
- Packing and Deploying Plugins as Add-ons *(on page 2565)*
- Add-ons Preferences *(on page 144)*
- Extending Oxygen XML Editor with Plugins *(on page 2530)*
- General Configuration of an Oxygen XML Editor Plugin *(on page 2530)*

Pretty-Print

Pretty-print refers to formatting and indenting the source code in **Text** mode to make the content easier to view and analyze. The formatting actions that are available in Oxygen XML Editor include:

- **Format and Indent Element** - Available in the **Source** submenu of the contextual menu for the current element.
- **Format and Indent** - Available on the toolbar for the entire current document.
- **Format and Indent Files** - Available in the contextual menu of the **Project** view *(on page 413)* for one or more selected files.

Project Options

Project Options refers to the storage option *(on page 320)* in the Oxygen XML Editor preference pages (**Options > Preferences**). If you select **Project Options** *(on page 321)*, the options in that particular preferences page are stored at project level in the project file (`.xpr`), which can easily be shared with other users *(on page 321)*.

QName

QName stands for "qualified name" and defines a valid identifier for elements and attributes. *QNames* are used as URI references to reference particular elements or attributes within XML documents.

Quick Assist

The ***Quick Assist*** feature gives you easy access to some of the most commonly used actions for the specific type of document you are editing. If one or more actions are available in the current context, they are accessible via a yellow bulb help ( ) placed at the current line in the stripe on the left side of the editor in **Text** mode. You can also invoke the quick assist menu by using the **Alt + 1** (**Meta + Alt + 1** on macOS) keyboard shortcuts.

Quick Fix

The ***Quick Fix*** support in Oxygen XML Editor helps you resolve errors that appear in an XML document by offering proposals to fix problems such as missing required attributes or invalid elements. *Quick Fixes* are available in **Text** mode and **Author** mode and they can be presented and activated in several ways.

- When hovering over an area of text where a validation error or warning occurs, the *Quick Fix* proposals can be presented as links in a tooltip pop-up window.
- When hovering over an error or warning in **Author** mode, the *Quick Fix* proposals are presented in a small drop-down menu.
- If you place the cursor in the highlighted area where a validation error or warning occurs, a *Quick Fix* icon ( ) is displayed in the stripe on the left side of the editor. Clicking that icon will allow you select from the available proposals.
- If you place the cursor in the highlighted area where a validation error or warning occurs, you can also access the *Quick Fix* menu by pressing **Alt + 1 (Command + Option + 1 on macOS)** on your keyboard.

Oxygen XML Editor also provides support for defining and customizing a library of *Quick Fixes* using the Schematron language *(on page 1270)*.

Root Map

A ***Root Map*** (or main map) specifies a *DITA map (on page 3419)* that defines a hierarchical structure of submaps that are contained within the *root map*. Essentially, the *root map* defines a scope and provides the mechanism to allow your defined keys to be propagated throughout the entire map structure (this mechanism is also known as a *key space (on page 3421)*).

In Oxygen XML Editor, the **DITA Maps Manager** includes an option on its toolbar where you can easily specify the *root map (on page 3077)*, but there are also several other ways to select or change the *root map (on page 3090)*.

Space-Preserved Element

A ***spaced-preserved element*** refers to elements that require white spaces and line endings to be preserved (for example, DITA `<codeblock>` and `<pre>` elements).

Subject Scheme Map

A ***Subject Scheme Map*** allows you to create custom controlled attribute values and to manage metadata. *Subject scheme maps* use a key definition to define a collection of controlled values rather than a collection of topics. The highest level of map that uses the set of controlled values must reference the *subject scheme map* where those controlled values are defined.

A controlled value is a keyword that can be used as a value in a metadata attribute. For example, the `@audience` metadata attribute may take a value that identifies the user group associated with a particular content unit (for medical equipment, that might include *therapist*, *oncologist*, *surgeon*, *radiologist*, and so on). In a *subject scheme map*, you can define a list of these audience values and you can then use these values to profile your content. For more information, see Customizing Profiling Values with a Subject Scheme Map *(on page 3337)*.

.

Track Changes

The *Track Changes* feature allows you to review changes that you or other authors have made and then accept or reject them. You can also manage the visualization mode of the tracked changes, add comments to changes, and mark them as being done. These actions are easily accessible from contextual menus, the toolbar, or the **Review** view *(on page 675)*.

For more information about this feature, see Managing Tracked Changes *(on page 654)*.

WebHelp Output Directory

WebHelp_OUTPUT_DIR refers to the output directory where WebHelp transformation files will be generated.

The output directory can be specified using the **Output Directory** text field in the **Output** tab of the transformation scenario dialog box.

When running the WebHelp transformation from a command line, the output directory can be specified using the `-o` or `--output` option.

Working Set

A ***Working Set*** refers to a set of files that will be used for the scope of search and refactoring operations. Many of the search and refactoring wizards include a step where you can specify the scope for the operation and you can choose one or more *working sets* to restrict the scope to that specified set of files.

XML Catalog

An ***XML Catalog*** maps a system ID or a URI reference for a resource (stored either remotely or locally) to a local copy of the same resource. Whenever XML processing relies on external resources (such as referenced schemas and stylesheets), the use of an *XML Catalog* becomes a necessity when Internet access is not available or the connection is slow.

Oxygen XML Editor includes default global catalogs as well as default catalogs for each of the built-in *frameworks (on page 3420)*, and you can also create your own. Oxygen XML Editor uses these *XML Catalogs* to resolve references for document validation and transformations. For more information, see Working with XML Catalogs *(on page 838)*.
